                                      struct security_attr_info_t *p_attr);
```

Parameters	
p	Base address of the target memory region
s	Size of the target memory region
p_attr	Pointer to the security_attr_info_t to be filled
Return	
void	None

tfm_get_secure_mem_region_attr()

tfm_get_secure_mem_region_attr() retrieves general secure memory protection configuration information of the target memory region according to the static system-level memory layout and fills the mem_attr_info_t.

```
void tfm_get_secure_mem_region_attr(const void *p, size_t s,
                                    struct mem_attr_info_t *p_attr);
```

Parameters	
p	Base address of the target memory region
s	Size of the target memory region
p_attr	Pointer to the mem_attr_info_t to be filled
Return	
void	None

tfm_get_ns_mem_region_attr()

tfm_get_ns_mem_region_attr() retrieves general non-secure memory protection configuration information of the target memory region according to the static system-level memory layout and fills the mem_attr_info_t.

```
void tfm_get_ns_mem_region_attr(const void *p, size_t s,
                                struct mem_attr_info_t *p_attr);
```

Parameters	
p	Base address of the target memory region
s	Size of the target memory region
p_attr	Pointer to the mem_attr_info_t to be filled
Return	
void	None

Secure Services

Secure Partition Manager

This document describes the Secure Partition Manager (*SPM*) implementation design in Trusted Firmware-M (*TF-M*).

Note:

- The FF-M in this document refers to the accumulated result of two specifications: FF-M v1.1 Update on FF-M v1.0.
- The words marked as *interpreted* are defined terms. Find the terms in referenced documents if it is not described in this document.

Introduction

The service access process of FF-M:

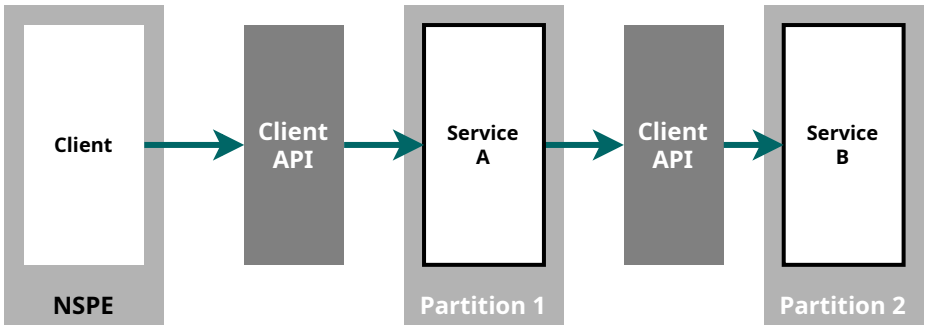

Fig. 5: FF-M service access process

Secure services (aka *Service*) is the component providing secure functionalities in *SPE*, and *Client* is the user of the *Service*. A service acts as a client when it is accessing its depending services.

Services are grouped into *Secure Partition* (aka *partition*). A partition:

- Contains services with the same purpose.
- Provides implementation required isolation boundaries.
- Is a software development unit.

Each service exposes its *Service ID* (*SID*) and *Handle* for client access usage. Clients access services by *SID* or *Handle* through FF-M *Client API*. Partitions use FF-M *Secure Partition API* when it needs to operate on client data or reply to a client.

SPM is the centre of an FF-M compliant implementation, which sets up and maintains a firmware framework that:

- Implements *Client API* and *Secure Partition API*.
- Manages partition runtime to follow FF-M.
- Involves necessary implementation-defined items to support the implementation.

SPM interfaces consist of these two categories:

- FF-M defined API.
- Extended API to support the implementation.

Both API categories are compliant with FF-M concepts and guidelines. The core concept of TF-M SPM surrounds the FF-M defined service management and access process. Besides this, another important implementation part is partition runtime management.

Partition runtime model

One partition must work under as *ONE* of the runtime models: *Inter-process communication* (*IPC*) model or *Secure Function* (*SFN*) model.

A partition that runs under the *IPC* model looks like a classic *process*. There is *ONE* thread inside the partition keeps waiting for signals. SPM converts the service accessing info from the *Client API* call into messages and assert a signal to the partition. The partition calls corresponded service function indicated by the signal and its bound message, and reply service returned result to the client. The advantages of this model:

- It provides better isolation by limiting the interfaces on data interactive. Data are preferred to be processed in a local buffer.
- It provides a mechanism for handling multiple service access. There is no memory mapping mechanism in the MCU system, hence it is hard to provide multiple function call contexts

when serving multiple-threaded clients if the service access is implemented in a function-call based mechanism. This model converts multiple service accesses into messages, let the partition handles the service access in messages one by one.

The *Secure Function* (*SFN*) model partition is close to a *library*. Each service is provided as a function entry inside the partition. SPM launches the target service function after the service is found. The whole procedure (from client to service function) is a function call. This model:

- Saves the workloads spent on *IPC* scheduling.

Meanwhile, it relaxes the data interactive mechanism, for example, allow direct memory access (MMIOVEC). And it is hard to enable multiple-threaded clients service access because of multiple call context-maintenance difficulties.

An implementation contains only *SFN* partitions fits better in the resource-constrained devices, it is called an *SFN model implementation*. And it is an *IPC model implementation* when *IPC* partitions exist in the system.

Note: *IPC model implementation* can handle access to the services in the *SFN* partition.

Components and isolation levels

There are *THREE* isolation levels defined in *FF-M*. These levels can fulfil different security requirements by defining different isolation boundaries.

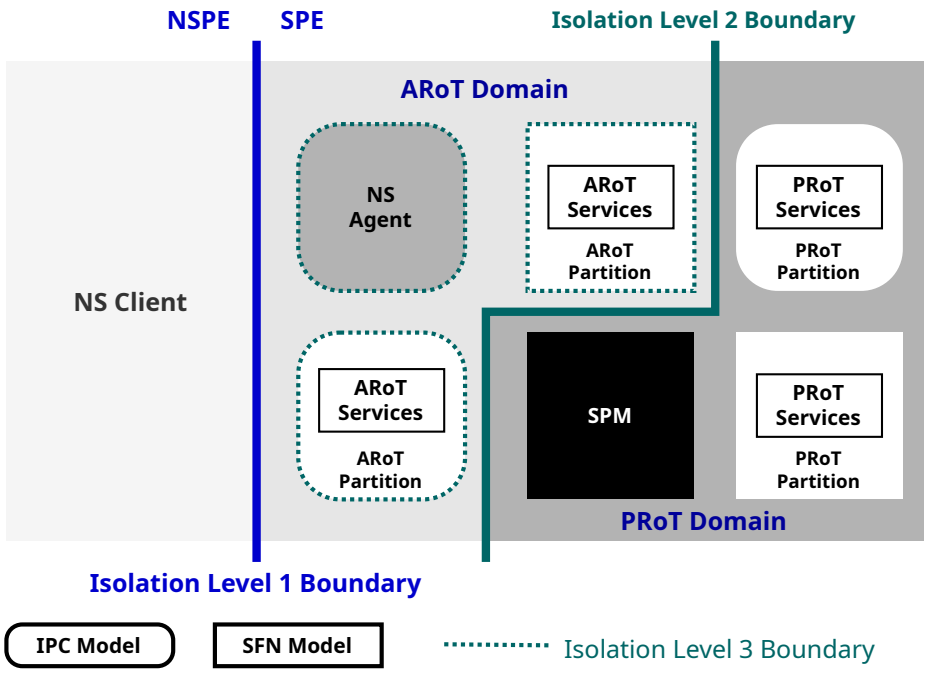

Fig. 6: Components and isolation boundaries

Note: Concept *ARoT*, *PRoT*, *domain*, and boundaries are in the *FF-M* specification.

Not like an *SPE* client that can call *Client API* to access the secure services in one step, an *NSPE* client needs to cross the secure boundaries first before calling *Client API*. The component *NS Agent* in fig-modelisolation represents *NSPE* clients after they crossed the secure boundaries. This could help *SPM* handles the request in a unified way instead of care about the special boundaries.

Note: *NS Agent* is a necessary implementation-defined component out of FF-M specification. *NS Agent* has a dedicated stack because secure and non-secure can not share the stack. It also has dedicated execution bodies. For example, RPC-based *NS Agent* has a while loop that keeps waiting for messages; and Trustzone-based *NS Agent* has veneer code to take over *NSPE* secure call. This makes *NS Agent* to be a component more like a *process*. Hence in the simplest implementation (*SFN model implementation* mentioned above), *NS Agent* is the only process in the system, the scheduling logic can be extremely simplified since no other process execution needs to be scheduled. But the scheduling interface is still necessary to SPM, this could help SPM treat both *SFN* and *IPC* model implementation in a unified way.

Check *NS Agent* for details.

Implementation principle

The principles for TF-M SPM implementation:

Important:

- SPM can treat these components as the client: NS Agent, SFN Partition, and IPC partition.
- These components can provide services: SFN Partition, IPC partition, and built-in services. A built-in service is built up with SPM together.
- All partition services must be accessed by *Client API*.
- Partitions interact with client data by *Secure Partition API*.
- Built-in services are strongly recommended to be accessed by *Client API*. Customized interfaces are restricted.
- Built-in services can call SPM internal interfaces directly.

Runtime management

The runtime execution runs among the components, there are **4** runtime states:

- *Initializing* state, to set up the SPM runtime environment after system powers up
- *IDLE* state, when SPM runtime environment is set up and partitions are ready for service access.
- *Serving* state, when partition is under initializing or service access handling.
- *Background* state, such as the arrival of secure interrupt or unexpected faults. *Background* state returns to the state it preempts. *Background* state can be nested.

The state transition diagram:

Initializing

The goal of TF-M initializing is to perform necessary initialization and move to the *Serving* state. This state starts with platform-specific power on sequence, then *SPM* takes over the execution to perform these operations:

1. A preparation initialization process before SPM runtime initialization.
2. SPM runtime initialization.
3. A post initialization happens after the SPM runtime initialization and before the first partition gets launched.

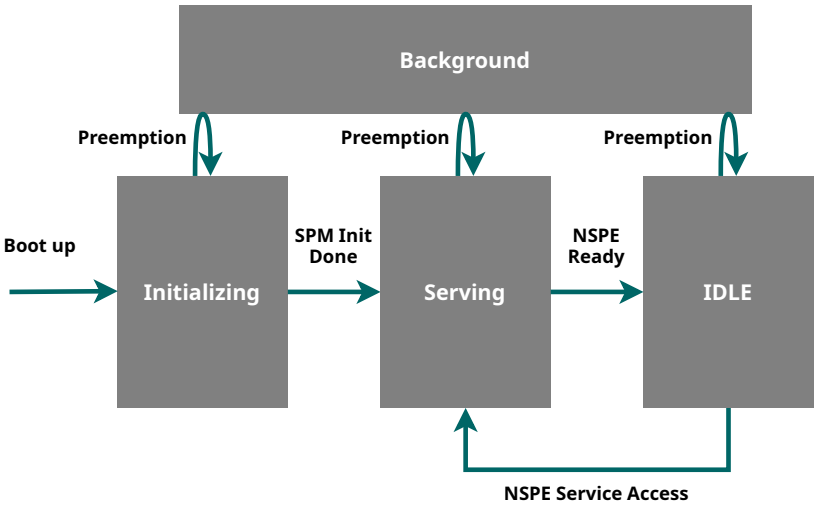

Fig. 7: SPE runtime execution states

Note: These procedures and their sub-routines are recommended to be applied with execution measurement mechansim to mitigate the *Hardware Fault Injection* attack.

Preparation initialization

The purpose of this preparation initialization is to provide a chance for performing those security required but generic platform power-on skipped operations, such as:

- Restrict *SPM* execution, for example, set up memory overflow settings for SPM runtime memory, or set code out of SPM as un-executable, even though SPM is a privileged component in general.

Note: The logging-related peripheral can be set up **AT THIS STEP**, if logging is enabled and it needs peripheral support. There is no standalone initializing HAL API proposed for logging, so here is an ideal place for initializing them.

This procedure is abstracted into one *HAL*, and a few example procedures are implemented as its sub-routines for reference:

- Architecture extensions initialization, Check chapter *Architecture security settings* for detailed information.
- Isolation and lifecycle initialization.

The load isolation boundaries need to be set up here, such as SPE/NSPE boundary, and ARoT/PRoT boundary if isolation level 2 is applied.

The lifecycle is initiated by a secure bootloader usually. And in this stage of SPM initializing, SPM double-checks the lifecycle set up status (following a specific lifecycle management guidelines). Note that the hardware debugger settings can be part of lifecycle settings.

Important: Double-check debugger settings when performing a product release.

SPM runtime initialization

This procedure initializes necessary runtime operations such as memory allocator, loading partitions and partition-specific initialization (binding partitions with platform resources).

The general processes:

1. Initialize runtime functionalities, such as memory allocator.
2. Load partitions by repeating below steps:
    - Find a partition load information.
    - Allocate runtime objects for this partition.
    - Link the runtime objects with load information.
    - Init partition contexts (Thread and call context).
    - Init partition isolation boundaries (MMIO e.g.).
    - Init partition interrupts.

After no more partitions need to be loaded, the SPM runtime is set up but partitions' initialization routines have not run yet - the partition runtime context is initialized for the routine call.

The partition initialization routine is a special service that serves SPM only, because:

- SPM needs to call the initialization routine, just like it calls into the service routine.
- The partition initialization routine can access its depending services. Putting initialization routine in the same runtime environment as common service routines can avoid special operations.

Hence a *Partition initialization client* needs to be created to initialize the SFN partitions, because:

- *SPM runtime initialization* happen inside a special runtime environment compare to the partition runtime execution, then an environment switching is needed.
- IPC partitions are initialized by the scheduler and dependencies are handled by signals and messages asynchronously, hence IPC partitions can process the dependencies by their own.

The *Partition initialization client* is created differently based on the implementation runtime model:

- A SFN client is created under the SFN model implementation.
- A IPC client is created under the IPC model implementation. This client thread has the highest priority.

As the other partitions, the client is created with context standby, and it is executed after the *Post initialization* stage.

Post initialization

Platform code can change specific partition settings in this procedure before partitions start. A few SPM API is callable at this stage, such as set a signal into a specific partition, or customized peripheral settings.

Serving

Two execution categories work under this state:

- *Partition initialization routine execution*.
- *Secure service access*.

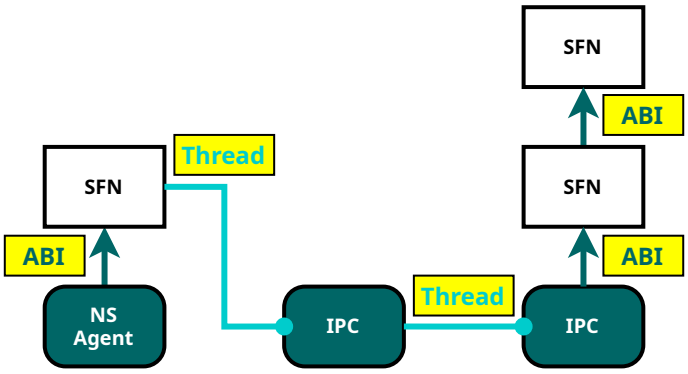
This state indicates the serving is ongoing. It is mainly the service routine execution, plus a few SPM executions when SPM API gets called.

Important: The service access process introduced in this chapter (Such as *Secure service access*) is abstracted from the FF-M specification. Reference the FF-M specification for the details of each step.

Partition initialization routine execution

The partition initialization routines get called. One partition may access its depending services during initializing, then this procedure is a *Secure service access*.

The initialization routine gets called initially by *Partition initialization client*, also can be called by Client API before service access, if the target partition is not initialized but a service access request is raised by one client.



Secure service access

The process of service access:

1. A *client* calls an FF-M Client API.
2. *SPM* validates inputs and looks up for the targeted service.
3. *SPM* constructs the request to be delivered under a proper runtime mechanism.
4. The target service gets executed. It can perform internal executions or access depending services to prepare the response. It also can wait for specific signals.
5. The target service calls FF-M Secure Partition API to request a reply to the client.
6. SPM delivers the response to the client, and the API called by the client returns.

The mechanism of how SPM interact with the target partition depends on the partition runtime model.

- Access to a service in an SFN partition is a function call, which does not switch the current process indicator.
- Access to a service in an IPC partition leads to scheduling, which switches the current process indicator.
- When the execution roams between components because of a function call or scheduling, the isolation boundaries NEED to be switched if there are boundaries between components.

No matter what kind of partition a client is trying to access, the SPM API is called firstly as it is the interface for service access. There are two ABI types when calling SPM API: Cross-boundary or No-cross-boundary.

Calling SPM API

SPM is placed in the PRoT domain. It MAY have isolation boundaries under particular isolation levels. For example:

- There are boundaries between ARoT components and SPM under isolation level 2 and 3.

The API SPM provided needs to support the function call (no boundary switching) and cross-boundary call. A direct call reaches the API entrance directly, while a cross-boundary call needs a mechanism (Supervisor call e.g.) to cross the boundary first before reaching the API entrance.

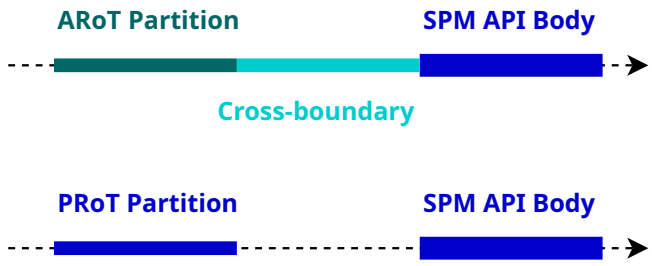


Fig. 8: SPM call types

SPM internal execution flow

SPM internal execution flow as shown in diagram:

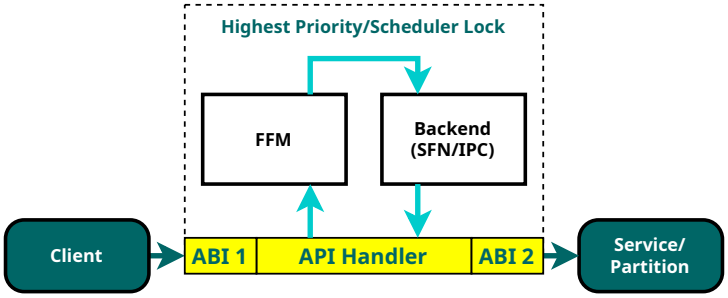

Fig. 9: SPM API runtime

The process:

- PSA API gets called by one of the ABI mentioned in the last chapter as *ABI 1* in the diagram.
- The unified API Handler calls FF-M and backend subroutines in sequence.
- The *FF-M* subroutine performs *FF-M* defined operations.
- The backend operations perform target partition runtime model decided operations. For example, enqueue message into the target partition under the IPC runtime model, or prepare to call context with the message as the parameters under the SFN runtime model.
- API Handler triggers different ABI based on the result of the backends.

The API handler:

- Can process the *PROGRAMMER_ERROR* in a unified place.
- Can see the prepared caller and callee context, with exited SPM context. It is an ideal place for subsequent operations such as context switching.

An example code:

```
void abi(void *p)
{
    status = spm_api(p);
    /*
     * Now both the caller and callee contexts are
     * managed by spm_api.
     */
    if (status == ACTION1) {
        /*
         * Check if extra operations are required
         * instead of a direct return.
         */
        exit_action1();
    }
}
```

The explanation about *Scheduler Lock*:

Some FF-M API runs as a generic thread to prevent long time exclusive execution. When a preemption happens, a new partition thread can call SPM API again, makes SPM API nested. It needs extra memory in SPM to be allocated to store the preempted context. Lock the scheduler while SPM API is executing can ensure SPM API complete execution after preemption is handled. There can be multiple ways to lock the scheduler:

- Set a scheduler lock.
- Set SPM API thread priority as the highest.

Backend service messaging

A message to service is created after the target service is found and the target partition runtime model is known. The preparation before ABI triggers the final accessing:

- The message is pushed into partition memory under a specific ABI mechanism if the target partition model is *SFN* and there are boundaries between SPM and the target partition. After this, requests a specific call type to the SPM ABI module.
- The target service routine is called with the message parameter if there are no boundaries between SPM and the target partition and the partition runtime is *SFN*.
- The message is queued into the partition message list if the target partition runtime model is *IPC*.
- IPC partition replies to the client by *psa_reply*, which is another SPM API call procedure.
- SFN partition return triggers an implied *psa_reply*, which is also another SPM API call procedure.

Note: The backends also handle the isolation boundary switching.

Sessions and contexts

FF-M API allows multiple sessions for a service if the service is classic connection-based. The service can maintain multiple local session data and use *rhandle* in the message body to identify which client this session is bound with.

But this does not mean when an ongoing service accessing is preempted, another service access request can get a chance for new access. This is because of the limited context storage - supporting multiple contexts in a common service costs much memory, and runtime operations (allocation and re-location). Limited the context content in the stack only can mitigate the effort, but this requirement requires too much for the service development.

The implementation-decisions are:

- IPC partitions handles messages one by one, the client gets blocked before the service replying to the client.
- The client is blocked when accessing services are handling a service request in an SFN partition.

ABI type summary

The interface type is decided by the runtime model of the target component. Hence PSA API has two types of ABI: *Cross-boundary ABI* and *Function call ABI*. After SPM operations, one more component runtime type shows up: The IPC partition, hence *schedule* is the mechanism when accessing services inside an IPC partition.

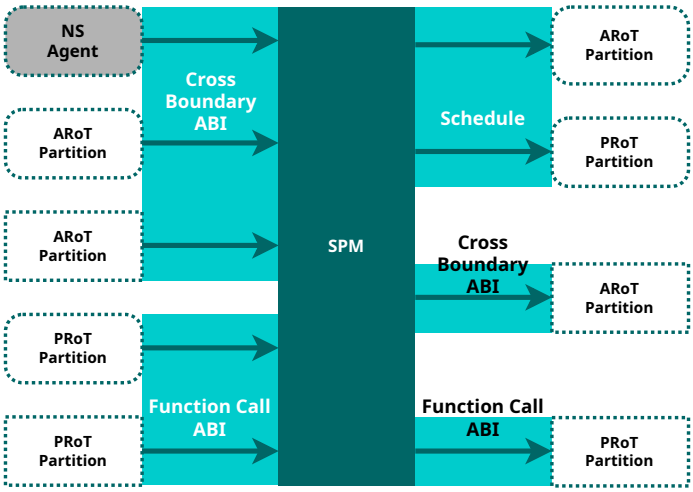

Fig. 10: ABI types

Note: The API that does not switch context returns directly, which is not covered in the above diagram.

IDLE state

The *IDLE state* can be represented by the *NS Agent* action:

- Launching NSPE software (Trustzone case, e.g.), or send a signal to NSPE software (RPC case, e.g.).

It is because *NS Agent* is the last component being initialized in the system. Its execution indicates other partitions' initialization has accomplished.

Background state

Background execution can happen at any time when the arrival of interrupts or execution faults. An ongoing background execution indicates the state is a *Background state*. The characteristics:

- The background state has a higher execution priority than other states - other states stall when the background state is executing.
- Background execution can be nested. For example, an interrupt handler can preempt an ongoing interrupt execution.
- Particular partition code can be involved in the background state, for example, the *First Level Interrupt Handler (FLIH)* of one partition.
- Background state MUST return to the state it preempts.

Note: Interrupt handling is a common background state example. Check Interrupt design document for details.

Practical implementation items

This chapter describes the practical implementation contents.

Important: Arm M-profile architecture is the default hardware architecture when describing architecture-specific items.

The general M-profile programming is not involved in this document. The following chapters introduce the mandatory settings for security requirements.

Architecture security settings

When an *Armv8m Security Extension* (Aka *Trustzone-M*) is available in the system, these settings are required to be set:

- The MSPLIM needs to be set correctly to prevent stack overflow.
- The exception handler priority needs to be decided.
- Boost the secure handler mode priority to prevent NSPE from preempting SPE handler mode execution(*AIRCR.PRIS*).
- Disable NSPE hardware faults when a secure fault is happening. Trap in the secure fault with the highest priority can be a valid option.
- Push seals on the stack top when a stack is allocated (*TFMV-1*). Also check *Stack seal* chapter for details.

Besides *Armv8m Security Extension*, these settings need to care when *Floatpoint Extension* is enabled for partition usage:

- *FPCCR.TS*, *FPCCR.CLRONRET* and *FPCCR.CLRONRETS* need to be set when booting.
- *CPACR.CP10* and *CPACR.CP11* need to be set when booting.

Important: Floatpoint usage is prohibited in SPM and background execution.

Stack seal

When Trustzone-M is applied, the architecture specification recommends sealing the secure stack by:

- Push two *SEAL* values (*0xFEF5EDA5*) at the stack bottom, when a stack is allocated.
- Push two *SEAL* values on the stack pointer which is going to be switched out.

Check architecture specification and vulnerability *TFMV-1* for details.

Trustzone-M reentrant

The Trustzone-M has characteristics that:

- SPE keeps the last assigned stack pointer value when execution leaves SPE.
- SPE execution can be preempted by NSPE which causes an execution left.

It is possible that NSPE preemption caused a second thread calls into SPE and re-uses the secure stack contains the first thread's context, which obviously causes information leakage and runtime state inconsistent.

Armv8.1-M provides the hardware setting *CCR_S.TRD* to prevent the reentrant. On an Armv8.0-M architecture, extra software logic needs to be added at the veneer entry:

- Check if the local stack points to a *SEAL* when veneer code get executed.

```
/* This is a theoretical code that is not in a real project. */
veneer() {
    content = get_sp_value();
    if (context != SEAL) /* Error if reentrant detected */
        error();
}
```

SPM Runtime ABI

This chapter describes the runtime implementation of SPM.

Scheduling

The scheduling logic is put inside the PendSV mode. PendSV mode's priority is set as one level higher than the default thread mode priority. If *Trustzone-M* is present, the priority is set as the lowest just above NS exception priority to prevent a preemption in secure exceptions.

PendSV is an ideal place for scheduling logic, because:

- An interrupt triggered scheduling during PendSV execution lead to another PendSV execution before exception return to the thread mode, which can find the latest run-able thread.

Function call ABI

In the diagram fig-abi_scheduler, the ABI can have two basic types: cross-boundary and direct call (No-cross-boundary).

When applying *SVCall* (*SVC*) as the cross-boundary mechanism, the implementation can be straight like:

- The SVC handler calls SPM internal routines, and eventually back to the handler before an exit.

Under the IPC model implementation, to re-use *ABI 2* in *No-cross-boundary*, a software ABI needs to be provided.

While under the SFN model plus isolation level 1, both *ABI 1* and *ABI 2* can be a direct function call.

NS Agent

The *NS Agent* (*NSA*) forwards NSPE service access request to SPM. It is a special *partition* that:

- It does not provide FF-M aligned secure services.
- It runs with the second-lowest priority under *IPC model implementation* (The IDLE thread has the lowest priority).
- It has isolation boundaries and an individual stack.
- It requires specific services and mechanisms compared to common partitions.

There are two known types for NS Agent:

- Trustzone-M based.
- Remote Procedure Call (RPC) based.

This process is put inside the ARoT domain, to prevent assign unnecessary PRoT permissions to the NSPE request parsing logic.

Trustzone-M specific

The functionalities of a Trustzone-M specific NSA is:

- Launch NSPE when booting.
- Wait in the veneer code, and get executed when NSPE accesses services.

As there may be multiple NSPE threads calling into SPE, and SPM wants to identify them, special mechanisms can be proposed to provide the identification. Check specific NS ID client ID or context related documents for details.

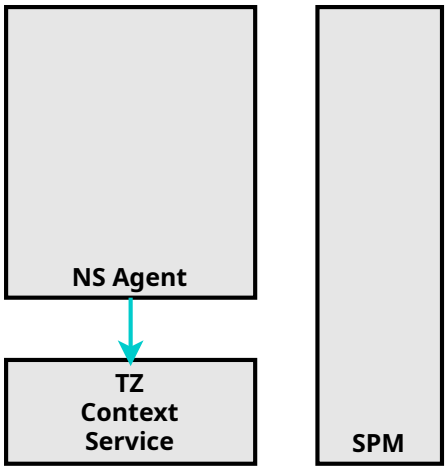

Fig. 11: TZ NSA and specific service

RPC specific

Compared to Trustzone-M NSA, RPC NSA looks closer to a generic partition:

- It has a message loop, keep waiting for RPC events.
- It converts received RPC events into FF-M API call to target services.

And compared to generic partitions, the differences are:

- It parses RPC messages to know which NSPE thread is accessing services. Hence it needs special interfaces to help SPM to identify the NSPE clients.
- It needs to check NSPE client memory and map to local before calling SPM API.
- It cannot be blocked during API calls, which affects handling the RPC requests.

Partition

A partition is a set of services in the same scope. Services are generally implemented as functions, and the partition exposes the services in different ways based on the partition model: *IPC* or *SFN*.

A partition build generates these outputs:

- A partition load information, used by SPM.
- A partition program containing service interface and logic, typically a library.
- An optional service API set for easier client usage, by encapsulating the low-level *FF-M* Client API. These API needs to be integrated into client space.

Partition loading

SPM needs to set up runtime objects to manage partitions by parsing the load information of partitions. In general, the partition load information is stored in a const memory area can be random read directly, hence SPM can direct link runtime objects to the load information without a copy operation. This is called a *Static Load* mechanism.

Each partition has different numbers of dependencies and services, this makes the load information size of each partition different, it would be hard to put such variable size elements in an array. The solution here is putting these elements in a dedicated section, for SPM enumerating while loading. Each partition can define variable size load information type based on the common load info type.

The common load information:

```
struct partition_load_info_t {
    uint32_t        psa_ff_ver;     /* Encode the version with magic    */
    int32_t         pid;            /* Partition ID                     */
    uint32_t        flags;          /* ARoT/PRoT, SFN/IPC, priority     */
    uintptr_t       entry;          /* Entry point                      */
    size_t          stack_size;     /* Stack size                       */
    size_t          heap_size;      /* Heap size                        */
    uint32_t        ndeps;          /* Dependency number                */
    uint32_t        nservices;      /* Service number                   */
    uint32_t        nassets;        /* Asset numbers                    */
    uint32_t        nirqs;          /* Number of IRQ owned by Partition */
};

And the example for a specific partition load info:
struct partition_example_load_info_t {
    struct partition_load_info_t ldi;      /* Common info info         */
    uint32_t                     deps[10]; /* Dependencies             */
    /*                 ... other infos ...                             */
};
```

Peripheral binding

A partition can declare multiple peripherals (Interrupts are part of peripherals). The peripherals binding process:

- The tooling references symbols in a fixed pattern in the partition load information.
- The HAL implementation needs to provide the symbols being referenced.
- SPM calls HAL API to bind the partition info with devices when the partition gets loaded.
- The platform HAL acknowledges the binding if validation pass on SPM given load information.

Integration and development

These modules are expected to be object/library level modularised, each module should be generated into object/library at build time:

Table 40: Object level modularization

Name	Description
SPM	All SPM related modules such as SPM, system, and so on.
Platform	Platform sources are switchable.
Services and Secure Partition	These items should be standalone.
Service Runtime Library	This is a shared runtime library.

HAL

The HAL here mainly refers to the SPM HAL. The SPM HAL implementation is running with the same privilege level and hardware mode with SPM. The implementation is object level modularized with SPM.

Check the *HAL* design document for details.

Configurations

The same TF-M code base is flexible to address different implementation requirements, from the simplest device with isolation level 1 to the most complicated device with isolation level 3 and optional isolation rules.

These configurations are set by switches, during the build time, as runtime support costs extra resources. The common configurations are named *profile*. There are several profiles defined.

History

Table 41: Revision

Date	Description
2021 Apr-Sep	Updated to cover the implementation for *FF-M v1.1* features.
2018	Created as 'TF-M Inter-Process Communication' which is deprecated as this document covers whole SPM content.

Secure Partition Runtime Library

Organization
Arm Limited

Contact
tf-m@lists.trustedfirmware.org

Background

Trusted Firmware - M (TF-M) uses a toolchain provided runtime library and supervisor calls to easily implement the PSA Firmware Framework (PSA FF) API. This working model works well under isolation level 1 since there are no data isolation requirements. While TF-M is evolving, this model is not suitable because:

- The high-level isolation requires isolating data but some toolchain library interfaces have their own global data which cannot be shared between the Secure Partitions.
- The toolchain libraries are designed without taking security as a core design principle.

A TF-M specific runtime library is needed for the following reasons:

- Easier evaluation or certification by security standards.
- Source code transparency.
- Sharing code to save ROM and RAM space for TF-M.

PSA FF specification also describes the requirements of C runtime API for Secure Partitions.

This runtime library is named the Secure Partition Runtime Library, and the abbreviation is SPRTL.

Design Principle

The following requirements are mandatory for SPRTL implementation:

Important:

- **CODE ONLY** - No read-write data should be introduced into runtime library implementation.
- **Thread safe** - All functions are designed with thread-safe consideration. These APIs access caller stack and caller provided memory only.
- **Isolation** - Runtime API code is set as executable and read-only in higher isolation levels.
- **Security first** - SPRTL is designed for security and it may come with some performance loss.

API Categories

Several known types of functions are included in SPRTL:

- C runtime API.
- RoT Service API.
- PSA Client and Service API.
- [Future expansion, to be detailed later] other secure API.

Security Implementation Requirements

If malloc/realloc/free are provided, they must obey additional requirements compared to the C standard: newly allocated memory must be initialized to ZERO, and freed memory must be wiped immediately in case the block contains sensitive data.

The comparison API ('memcmp' e.g.), they should not return immediately when the fault case is detected. The implementation should execute in linear time based on input to avoid execution timing side channel attack.

The pointer validation needs to be considered. In general, at least the 'non-NULL' checking is mandatory. A detection for invalid pointer leads to a psa_panic().

The following section describes the first 3 API types and the implementation requirements.

C Runtime API

PSA FF describes a small set of the C standard library. Part of toolchain library API can be used as default if these APIs meet the *Design Principle* and *Security Implementation Requirements*. The toolchain 'header' and 'types' can be reused to simplify the implementation.

These APIs can take the toolchain provided version, or separately implemented in case there are extra requirements:

Note:

- 'memcpy()/memmove()/memset()'
- String API

These APIs are proposed to be implemented with the security consideration mentioned in *Security Implementation Requirements*:

Note:

- 'memcmp()'

- Other comparison API if referenced ('strcmp' e.g.).

The following functions are optional, but if present, they must conform to additional *Security Implementation Requirements*:

Note:

- 'malloc()/free()/realloc()'
- 'assert()/printf()'

The following APIs are coupled with toolchain library much so applying toolchain library implementation is recommended:

Note:

- Division and modulo - arithmetic operations.
- Other low level or compiler specific functions (such as 'va_list').

Besides the APIs mentioned above, the following runtime APIs are required for runtime APIs with private runtime context ('malloc' e.g.):

Note:

- '__sprtmain()' - partition entry runtime wrapper.

RoT Service API

The description of RoT Service API in PSA FF:

Note: Arm recommends that the RoT Service developer also defines an RoT Service API and implementation to encapsulate the use of the IPC protocol, and improve the usability of the service for client firmware.

Part of the RoT Service API have proposed specifications, such as the PSA Cryptography API, PSA Storage API, and PSA Attestation API. It is suggested that the service developer create documents of their RoT Service API and make them publicly available.

The RoT Service API has a large amount and it is the main part of SPRTL. This chapter describes the general implementation of the RoT Service API and the reason for putting them into SPRTL.

In general, a client uses the PSA Client API to access a secure service. For example:

```
/* Example, not a real implementation */
caller_status_t psa_example_service(void)
{
  ...
  handle = psa_connect(SERVICE_SID, SERVICE_VERSION);
  if (INVALID_HANDLE(handle)) {
    return INVALID_RETURN;
  }

  status = psa_call(handle, type, invecs, inlen, outvecs, outlen);

  psa_close(handle);
```

(continues on next page)

(continued from previous page)

```
  return TO_CALLER_STATUS(status);
}
```

This example encapsulates the PSA Client API, and can be provided as a simpler and more generic API for clients to call. It is not possible to statically link this API to each Secure Partition because of the limited storage space. The ideal solution is to put it inside SPRTL and share it to all Secure Partitions. This would simplify the caller logic into this:

```
if (psa_example_service() != STATUS_SUCCESS) {
  /* do something */
}
```

This is the simplest case of encapsulating PSA Client API. If a RoT Service API is connect heavy, then, the encapsulation can be changed to include a connection handle inside a context data structure. This context data structure type is defined in RoT Service headers and the instance is allocated by API caller since API implementation does not have private data.

Note:

- Even the RoT Service APIs are provided in SPRTL for all clients, the SPM performs the access check eventually and decides if the access to service can be processed.
- For those RoT Service APIs only get called by a specific client, they can be implemented inside the caller client, instead of putting it into SPRTL.

PSA Client and Service API

Most of the PSA APIs can be called directly with supervisor calls. The only special function is psa_call, because it has **6** parameters. This makes the supervisor call handler complex because it has to extract the parameters from the stack. The definition of psa_call is the following:

```
psa_status_t psa_call(psa_handle_t handle, int32_t type,
                      const psa_invec *in_vec, size_t in_len,
                      psa_outvec *out_vec, size_t out_len);
```

The parameters need to be packed to avoid passing parameters on the stack, and the supervisor call needs to unpack the parameters back to **6** for subsequent processing.

Privileged Access Supporting

Due to specified API (printf, e.g.) need to access privileged resources, TF-M Core needs to provide interface for the resources accessing. The permission checking must happen in Core while caller is calling these interface.

Secure Partition Local Storage

There are APIs that need to reference specific partition private data ('malloc' references local heap, e.g.), and the APIs reference the data by mechanisms other than function parameters. The mechanism in TF-M is called 'Secure Partition Local Storage'.

A straight way for accessing the local storage is to put the local storage pointer in a known position in the stack, but there is a bit of difficulty in particular scenarios.

Note:

- The partition's stack is not fixed-size aligned, using stack address aligning method can not work.

- It requires privileged permission to *access* special registers such as *PSPLIMIT*. And Armv6-M and Armv7-M don't have *PSPLIMIT*.'

Another common method is to put the pointer in one shared global variable, and the scheduler maintains the value of this variable to point to the running partition's local storage in runtime. It does not fully align with SPRTL design prerequisites listed above, hence extra settings are required to guarantee the isolation boundaries are not broken.

Important:

- This variable is put inside a dedicated shared region and it can not hold information not belonging to the owner.

And this mechanism has disadvantages:

- It needs extra maintenance effort from the scheduler and extra resources for containing the variable.

TF-M chooses this common way as the default option for local storage and can be expanded to support more methods.

Tooling Support on Partition Entry

PSA FF requires each Secure Partition to have an entry point. For example:

```
/* The entry point function must not return. */
void entry_point(void);
```

Each partition has its own dedicated local_storage for heap tracking and other runtime state. The local_storage is designed to be saved at the read-write data area of a partition with a specific name. A generic entry point needs to be available to get partition local_storage and do initialization before calling into the actual partition entry. This generic entry point is defined as '__sprtmain':

```
void ___sprtmain(void)
{
  /* Get current SP private data from local storage */
  struct p_sp_local_storage_t *m =
          (struct p_sp_local_storage_t *)tfm_sprt_local_storage;

  /* Potential heap init - check later chapter */
  if (m->heap_size) {
    m->heap_instance = tfm_sprt_heap_init(m->heap_sa, m->heap_sz);
  }

  /* Call thread entry 'entry_point' */
  m->thread_entry();

  /* Back to tell Core end this thread */
  SVC(THREAD_EXIT);
}
```

Since SPM is not aware of the '__sprtmain' in SPRTL, it just calls into the entry point listed in partition runtime data structure. And the partition writer may be not aware of running of '__sprtmain' as the generic wrapper entry, tooling support needs to happen to support this magic. Here is an example of partition manifest:

```
{
  "name": "TFM_SP_SERVICE",
  "type": "PSA-ROT",
```

(continues on next page)

(continued from previous page)

```
  "priority": "NORMAL",
  "entry_point": "tfm_service_entry",
  "stack_size": "0x1800",
  "heap_size": "0x1000",
  ...
}
```

Tooling would do manipulation to tell SPM the partition entry as '__sprtmain', and TF-M SPM would maintain the local storage at run time. Finally, the partition entry point gets called and run, tooling helps on the decoupling of SPM and SPRTL implementation. The pseudo code of a tooling result:

```
struct partition_t sp1 {
  .name = "TFM_SP_SERVICE",
  .type = PSA_ROT,
  .priority = NORMAL,
  .id = 0x00000100,
  .entry_point = ___sprtmain, /* Tell SPM entry is '___sprtmain' */
  .local_storage = { /* struct sprt_local_storage_t */
    .heap_sa = sp1_heap_buf,
    .heap_sz = sizeof(sp1_heap_buf),
    .thread_entry = sp1_entry, /* Actual Partition Entry */
    .heap_instance = NULL,
  },
}
```

Implementation

The SPRTL C Runtime sources are put under: '$TFM_ROOT/secure_fw/partitions/lib/runtime/'

The output of this folder is a static library named as 'libtfm_sprt.a'. The code of 'libtfm_sprt.a' is put into a dedicated section so that a hardware protected region can be applied to contain it.

The RoT Service API are put under service interface folder. These APIs are marked with the same section attribute where 'libtfm_sprt.a' is put.

The Formatting API - 'printf' and variants

The 'printf' and its variants need special parameters passing mechanism. To implement these APIs, the toolchain provided builtin macro 'va_list', 'va_start' and 'va_end' cannot be avoided. This is because of some scenarios such as when 'stack canaries' are enabled, only the compiler knows the format of the 'canary' in order to extract the parameters correctly.

To provide a simple implementation, the following requirements are defined for 'printf':

- Format keyword 'xXduscp' needs to be supported.
- Take '%' as escape flag, '%%' shows a '%' in the formatted string.
- To save heap usage, 32 bytes buffer in the stack for collecting formatted string.
- Flush string outputting due to: a) buffer full b) function ends.

The interface for flushing can be a logging device.

Function needs implied inputs

Take 'malloc' as an example. There is only one parameter for 'malloc' in the prototype. Heap management code is put in the SPRTL for sharing with caller partitions. The heap instance belongs to each partition, which means this instance needs to be passed into the heap management code as a parameter. For allocation API in heap management, it needs two parameters - 'size' and 'instance', while for 'malloc' caller it needs a 'malloc' with one parameter 'size' only. As

mentioned in the upper chapter, this instance can be retrieved from the Secure Partition Local Storage. The implementation can be:

```
void *malloc(size_t sz)
{
    struct p_sp_local_storage_t *m =
        (struct p_sp_local_storage_t *)tfm_sprt_local_storage;

    return tfm_sprt_alloc(m->heap_instance, sz);
}
```

Terminology

IPC - Inter-Process Communication

For more terminology please check *Reference* document.

Design Overview

Components for implementing IPC:

- SPM – for partition information and isolation actions
- Core – for exception handling
- Memory pool
- Message manager
- Thread
- Synchronization objects
- PSA API

Implementation Details

Listed modules are all internal modules except PSA API. Prototypes and definitions are not listed for internal modules in this document. For PSA API definitions, check them in PSA Firmware Framework specification in the reference chapter.

SPM and Core

SPM manages Secure Partition information. Enhancements need to be done in SPM data structure for Secure Partition for IPC due to:

- IPC model requires each Secure Partition has its own stack area.
- Multiple services are holding in same Secure Partition and each service has its own information like message queue, SID and priority.
- Changed information related manifest items need to be changed, too.

Modifications in Core:

- More SVC calls need to be added into list since PSA API are implemented as SVC calls in TF-M.
- New PendSV handler for thread scheduling.
- Arch-related context stacking and switching.

Memory Pool

Handles of connection and messages for Secure Partition needs to be allocated dynamically. A memory pool is provided in the system to handle dynamic allocation. Each memory pool item contains below information:

- A list iterator to chain all of memory pool items.
- An information member to record information like size and types.
- The memory item body for caller usage.

A memory area needs to be provided in SPM for the memory pool. It could be an array of memory areas defined in the linker script. Two chains are available to manage the items: free chain and used chain. And an LRU (Last recent used) mechanism is applied for fast seeking while item allocating and destroying.

Message Manager

Message Manager handles message creating, pushing, retrieving and destroy. A message contains below information:

- Message sender and destination
- Message status
- IO vectors for service
- 'psa_msg_t' for service

A checking needs to be performed in SPM before creating a message to detect if a message with the same sender and destination is ongoing. This avoids repeat messages are available in the queue.

Thread

Each Secure Partition has a thread as execution environment. Secure Partition is defined statically in TF-M manifest, which indicates that a number of threads are statically defined. Threads are chained in SPM and sorted with its priority, and there is an extra indicator point to first running thread with the highest priority. This helps fast seeking of running threads while the scheduler is switching threads.

Thread context contains below information:

- Priority
- Status
- Stack pointer
- Stack pointer limitation
- Entry
- Parameter
- Entry return value
- Context

- List iterator

Thread API provides below functions:

- Thread creating and destroying
- Thread status retrieving and changing
- Current thread retrieving
- Thread context switching

PendSV exception in TF-M core is the place thread context APIs been called. Before thread switching taking place, isolation status needs to be changed based on Secure Partition change and current isolation level – a thread is a member of partition which means thread switching caused a partition switching.

Synchronization API

A first synchronization object is an event. This could be applied into event waiting in the partition, and message response handling in IPC. The event object contains below members:

- Owner thread who is waiting for this event
- Event status (Ready or Not-Ready)
- List iterator for synchronization objects management

Event API Limitation: could be waited by one thread only.

PSA API

This chapter describes the PSA API in an implementation manner.

- API type: could be Client API and Service Partition API
- Block-able: Block-able API may block caller thread; Non-Block API does not block caller thread.
- Description: The functionality description and important comments.

```
uint32_t psa_framework_version(void);
uint32_t psa_version(uint32_t sid);
```

- Client API
- Non-Block API
- These 2 functions are finally handled in SPM and return the framework version or version to the caller.

```
psa_handle_t psa_connect(uint32_t sid, uint32_t version);
psa_status_t psa_call(psa_handle_t handle, int32_t type,
                      const psa_invec *in_vec, size_t in_len,
                      psa_outvec *out_vec, size_t out_len);
void psa_close(psa_handle_t handle);
```

- Client API
- Block-able API
- These 3 APIs are implemented in the same manner and just different parameters. SPM converts each call into a corresponding message with a parameter in the message body and pushes the message into service queue to wait for the response. Scheduler switches to a specified thread (partition) and makes Secure Partition to have chance retrieving and process message. After a message response is returned to the caller, the waiting caller gets to go and get the result.

```
psa_signal_t psa_wait(psa_signal_t signal_mask, uint32_t timeout);
```

- Secure Partition API
- Block-able API
- This API blocks caller partition if there is no expected event for it. This function is implemented based on event API.

```
void psa_set_rhandle(psa_handle_t msg_handle, void *rhandle);
psa_status_t psa_get(psa_signal_t signal, psa_msg_t *msg);
size_t psa_read(psa_handle_t msg_handle, uint32_t invec_idx,
                void *buffer, size_t num_bytes);
size_t psa_skip(psa_handle_t msg_handle, uint32_t invec_idx,
                size_t num_bytes);
void psa_write(psa_handle_t msg_handle, uint32_t outvec_idx,
               const void *buffer, size_t num_bytes);
void psa_reply(psa_handle_t msg_handle, psa_status_t status);
void psa_clear(void);
void psa_eoi(psa_signal_t irq_signal);
```

- Secure Partition API
- Non-Block
- These APIs do not take the initiative to change caller status. They process data and return the processed data back to the caller.

```
void psa_notify(int32_t partition_id);
```

- Secure Partition API
- Non-Block
- This API sets DOORBELL bit in destination partition's event. This API does not take the initiative to change caller status.

```
void psa_panic(void);
```

- Secure Partition API
- Block-able API
- This function will terminate execution within the calling Secure Partition and will not return.

Stateless Root of Trust Services Reference

Author
Mingyang Sun

Organization
Arm Limited

Contact
mingyang.sun@arm.com

Introduction

This document describes the implementation for the FF-M v1.1 feature - 'Stateless RoT Service', and the related references when developing RoT services.

It is recommended to refer to the FF-M v1.0 specification[1] and FF-M v1.1 extension[2] for background and rationale details.

Implementation Details

This chapter describes the implementation-defined items, including stateless handle value definition, tooling update, and programming API changes.

Stateless Handle Value Definition

The index, stateless indicator, and service version information are encoded into a handle by the manifest tooling, and then generated to header file sid.h.

Table 42: Bit Fields of Stateless Handle

Bits	Field Description
bit 31	reserved
bit 30	stateless handle indicator bit, always 1
bit 29 - bit 16	reserved
bit 15 - bit 8	service version requested by client - for client version check
bit 7 - bit 5	reserved
bit 4 - bit 0	the handle index, [0, 31]

Since connection-based services and stateless services share the same PSA API psa_call(), an indicator bit is set in the handle indicate the type of the handle. If it is set, the handle is stateless, and definition is as described in the table above. Maximum connection-based handle is 0x3FFFFFFF, thus the indicator bit is always 0.

The index is used for organizing stateless services in manifest tool and locating a stateless service in SPM logic. A range of index [0, 31] is the initial implementation. Future expansion is possible.

Tooling Support

TF-M provides a tool (tools/tfm_parse_manifest_list.py) to generate source header files required by partition and services. For example, the generated sid.h contains service ID and version. The tooling is extended to generate stateless handle from partition manifests automatically.

The stateless_handle attribute in manifest is only supported by partitions with firmware framework version 1.1.

- If stateless_handle in manifest is set to an integer, the index is stateless_handle - 1.
- If it is auto or not set, the first empty index in range [0, 31] is assigned.
- Other settings - tooling reports an error.

Finally, the tooling encodes the handle according to definitions in *Stateless Handle Value Definition* section, and writes them to sid.h header file.

Changes in Programming API

[1] FF-M v1.0 Specification
[2] FF-M v1.1 Extension

This chapter describes the changes in programming API for stateless services. The following APIs' behavious and message data structure members are updated to support the stateless service.

psa_connect()

According to FF-M v1.1, client calling psa_connect() with the SID of a stateless RoT Service is a PROGRAMMER_ERROR.

psa_close()

According to FF-M v1.1, client passing a stateless handle to call this API is a PROGRAMMER_ERROR.

psa_call()

```
psa_status_t psa_call(psa_handle_t handle, int32_t type,
                      const psa_invec *in_vec, size_t in_len,
                      psa_outvec *out_vec, size_t out_len)
```

API parameters and behaviour change:

1. The handle parameter must be a stateless handle defined in psa_manifest/sid.h when requesting a stateless service.
2. This API validates stateless handle, decodes index and service version information from it. SPM uses the index to know which stateless service is requested.
3. This API performs some operations as psa_connect() does, such as the authorization check, service and client version check, and handle space allocation.

Service behaviour change during a "psa_call":

Service does not accept connection and disconnection messages. After a "psa_call" request is serviced, it calls psa_reply(), frees the connection handle to handle pool.

psa_set_rhandle()

According to FF-M v1.1, stateless service calling this API on a message is a PROGRAMMER_ERROR and it will never return.

psa_msg_t type

The rhandle member of a psa_msg_t type received by a stateless RoT Service is always NULL.

Application Recommendation

There are particular services that do not need sessions. The access to the service is a one-shot connection. These services provide standalone operations that do not require any non-volatile state of resources to be maintained by the RoT service itself or do not expose any kind of context or session to the caller. Such services are recommended to be implemented as stateless, to provide quick access and to avoid extra overheads.

In this case, rhandle access would be prohibited as it is used for saving state or non-volatile resources while stateless services do not need them.

Update Feasibility of Existing Services

TF-M native services are used widely. They only need standalone operations and do not need to keep state between sessions. For example, the service in Crypto partition does not do anything during psa_connect() or psa_close() process. Same for services in other partitions, thus all of them can be implemented as stateless.

Analysis for them:

Table 43: TF-M Partition Services Update Possibility

Partition	Number of Services	Can be Stateless
ITS	4	All
PS	5	All
Crypto	1	All
FWU	6	All
Platform	4	All
Initial Attestation	2	All

Other services are not analyzed here.

Grouping Services

Stateless service table is stored statically, and TF-M supports 32 stateless services currently.

Similar stateless services in a partition could be grouped, and assign one SID for the group. The type parameter in psa_call() could be extended to identify the service in group. In this case, it is recommended to use consecutive values for type.

It is recommended that each Secure Partition declares one stateless service and uses the type parameter to distinguish different stateless services. Therefore, more stateless services can be supported.

Migrating to Stateless Services

Please refer to Chapter 4 “Stateless Root of Trust services”, Appendix B.3.2 “Using a stateless RoT Service”, and Appendix D “Implementing session-less RoT Services” in FF-M v1.1 document for details on which kind of service can be stateless and how to implement a stateless service.

Uniform Secure Service Signature

Author
Miklos Balint

Organization
Arm Limited

Contact
Miklos Balint <miklos.balint@arm.com>

Declaring secure service interface

The following alternative secure service signature is proposed as an amendment to existing implementation.

Individual signatures - current method

A <service_name>_veneers.c file is created in the secure_fw/ns_callable directory, that specifies the signature for each veneer function, and calls the secure function from the veneers. The respective interface/include/<service_name>_veneers.h file with the veneer declarations have to be created and maintained manually. Note that at present TF-M framework limits the range of valid return values a secure service can provide, reserving a range for framework error codes.

Uniform signatures - proposal

The proposal is to use a uniform signature for all the secure functions of the secure service. There are multiple advantages of this method:

- TF-M Core can do a sanity check on the access rights of the veneer parameters, and there is no need for the secure services to make these checks individually. Please note that in the present implementation sanity check is only fully supported for level 1 isolation.
- The veneer declarations and implementations for the secure functions can be generated automatically from a template (using the secure function list in the secure service's manifest)

The signature for such secure services would look like this:

```
psa_status_t secure_function_name(struct psa_invec *in_vec, size_t in_len,
                                  struct psa_outvec *out_vec, size_t out_len);
```

where

Return value:

psa_status_t is a status code whose values are described in PSA Firmware Framework (as in version 1.0-beta-0 chapter 4.3.3).

Note:

The return value limitations imposed by TF-M framework for proprietary secure service veneers would not apply to secure services using the uniform signature. This is analogous to how PSA Firmware Framework handles values returned by psa_reply() function.

Arguments:

```
/**
 * A read-only input memory region provided to a RoT Service.
 */
typedef struct psa_invec {
    const void *base;   /*!< the start address of the memory buffer */
    size_t len;         /*!< the size in bytes */
} psa_invec;

/**
 * A writable output memory region provided to a RoT Service.
 */
typedef struct psa_outvec {
    void *base;         /*!< the start address of the memory buffer */
    size_t len;         /*!< the size in bytes */
} psa_outvec;

/**
 * in_len: the number of input parameters, i.e. psa_invecs
 * out_len: the number of output parameters, i.e. psa_outvecs
 */
```

The number of vectors that can be passed to a secure service is constrained:

```
in_len + out_len <= PSA_MAX_IOVEC
```

The veneer function declarations and implementations are generated in the interface/include/tfm_veneers.h and secure_fw\ns_callable\tfm_veneers.c files respectively. The veneer functions are created with the name tfm_<secure_function_name>_veneer

Services that implement the uniform signature do not need to manually fill the template veneer function to call TFM_CORE_SFN_REQUEST macro.

Compatibility

Note that the proposal is for the two types of services (those with proprietary signatures and those with uniform signatures) to co-exist, with the intention of eventually phasing out proprietary signatures in favour of the more robust, uniform signature.

Abstract

This document describes the design of the TF-M Cryptographic Secure Service (in short, TF-M Crypto service).

Introduction

The TF-M Crypto service provides an implementation of the PSA Certified Crypto APIs in a PSA RoT secure partition in TF-M. It is based on the Mbed TLS project, which provides a reference implementation of the PSA Crypto APIs as a *C* software library. For more details on the PSA Crypto APIs refer to[1], while for the Mbed TLS reference software refer to[2] and[3]

[1] PSA Certified Crypto API specifications: https://arm-software.github.io/psa-api/crypto/
[2] Using PSA - Getting started in Mbed TLS: https://mbed-tls.readthedocs.io/en/latest/getting_started/psa/
[3] Mbed TLS repository which holds the reference implementation as a *C* software library: https://github.com/Mbed-TLS

The service can be requested by other services running in the SPE, or by applications running in the NSPE, and its aim is to provide cryptographic primitives in a secure and efficient way, either via software or by routing the calls to any underlying crypto hardware accelerator or secure element that the platform might provide.

Components

The TF-M Crypto service is implemented by a number of different firmware components residing in the Crypto partition, which are listed below:

Table 44: Components table

Component name	Description	Location
Client API interface	This module exports the PSA Crypto API to be callable from the users, which are called also *clients*. They could be either other secure partitions or Non Secure world based callers.	interface/src/tfm_crypto_api.c
Mbed TLS libmbedcrypto.a	The Mbed TLS libmbedcrypto.a library is used in the service as a cryptographic *backend* library which provides the APIs to implement a PSA Crypto *core*, SW based crypto primitives and wrappers for HW crypto accelerators and Secure Elements. It exposes those through the PSA Crypto APIs	Needed as dependency specified by the MBEDCRYPTO_PATH CMake configuration option
Init module	This module handles the initialisation of the service objects during TF-M boot and provides the infrastructure to service requests when TF-M is built for IPC or SFN model. The dispatching mechanism of IPC requests is based on a look up table of function pointers. This design allows for better scalability and support of a higher number of Secure functions with minimal overhead and duplication of code. This module is in charge of providing an ID of the caller of each API in the backend, allowing to enforce key ownership policies.	secure_fw/partitions/crypto/crypto_init.c
Alloc module	This module handles the allocation of contexts for multipart operations in the Secure world. This is required because the caller view of contexts, i.e. *clients*, does not contain any sensible information but just a number handle which is then used by the service itself to match the context to the actual context information which will be stored securely in the TF-M crypto partition private memory. This is enabled by setting MBEDTLS_PSA_CRYPTO_CLIENT option on the caller side. Note that setting this option on the client side is a hard requirement in order for the clients to work correctly	secure_fw/partitions/crypto/crypto_alloc.c
Service modules	These modules (AEAD, Asymmetric, Cipher, Hash, Key Derivation, Key Management, MAC, Random Number Generation) represent a thin layer which is in charge of servicing the calls from the clients. They provide parameter sanitization and context retrieval for multipart operations, and dispatching to the corresponding backend library function exposed by the underlying library.	secure_fw/partitions/crypto/crypto_aead.c secure_fw/partitions/crypto/crypto_asymmetric.c secure_fw/partitions/crypto/crypto_cipher.c secure_fw/partitions/crypto/crypto_hash.c secure_fw/partitions/crypto/crypto_key_derivation.c secure_fw/partitions/crypto/crypto_key_management.c secure_fw/partitions/crypto/crypto_mac.c secure_fw/partitions/crypto/crypto_rng.c
Backend library abstraction	This module contains several APIs to abstract the interface towards the backend library, which must provide the PSA Crypto core layer, key management, SW based crypto and possibly interfaces for HW crypto accelerators and Secure Elements	secure_fw/partitions/crypto/crypto_library.*

The interaction between the different components is described by the block diagram in block_diagram-label

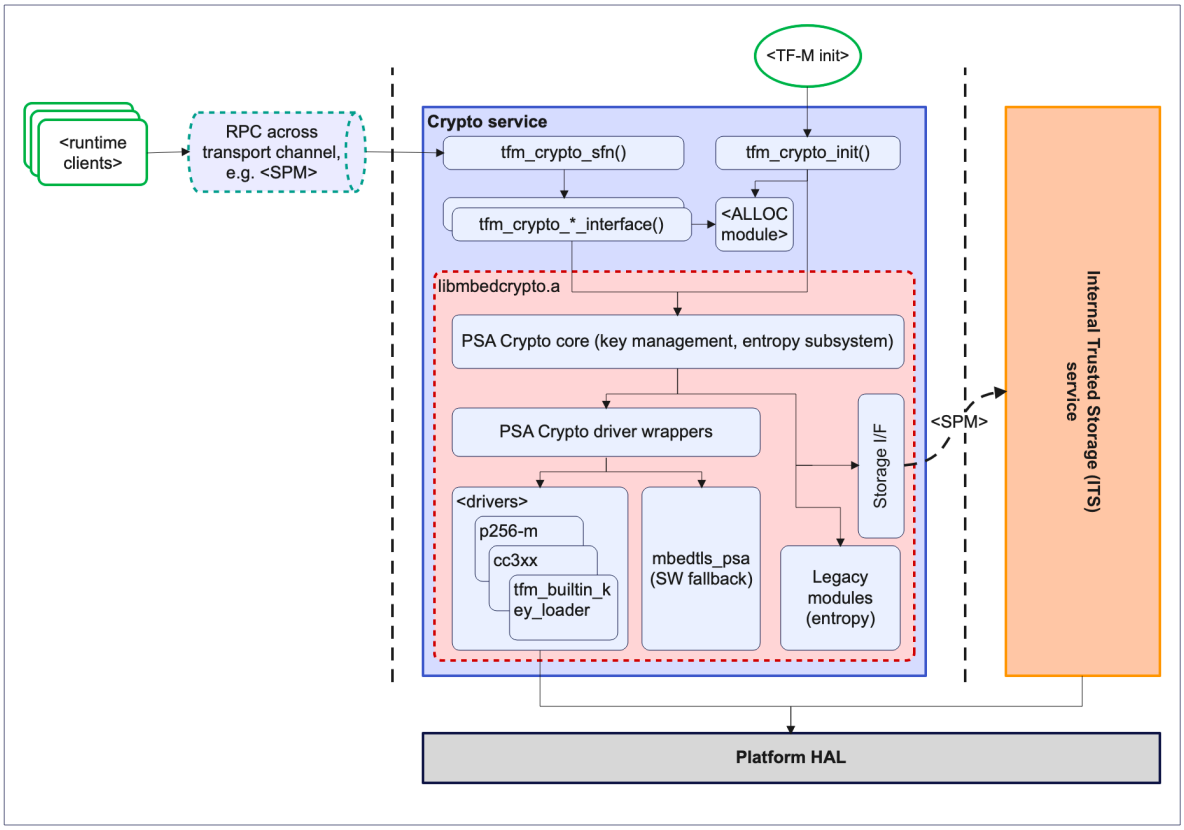

Fig. 12: Block diagram of the firmware architecture of the TF-M Crypto service. Dotted lines between services represent isolation boundaries once runtime firmware is initialized, i.e. TF-M init phase has completed. The diagram is simplified and shows only the major functional blocks, for a more detailed libmbedcrypto.a architecture please refer to[Page 1164, 3].

Relationship between Mbed TLS and the TF-M Crypto service

TF-M Crypto as a particular configuration of Mbed TLS

Up until *TF-Mv2.0*, the TF-M Crypto service used to provide its own separate implementation of the PSA Certified Crypto APIs, i.e. it provided its own version of the implementation defined aspects of the specifications. Starting from *TF-Mv2.1*, the TF-M Crypto service fully aligns to the implementation defined by the Mbed TLS project, i.e. its implementation defined aspects are the same as the ones defined by Mbed TLS.

As a consequence, starting from *TF-Mv2.1* the PSA Crypto headers available in TF-M are a copy of those distributed by the Mbed TLS project. TF-M just uses them and won't accept any contribution to them, as those need to be discussed in the scope of the Mbed TLS project.

TF-M then represents just a configuration of the Mbed TLS reference implementation where the TF-M Crypto APIs are provided as a remote call across a transport channel, which might be represented by a TrustZone boundary (in Armv8.x-M systems), by a mailbox channel in heterogeneous systems, e.g. Cortex-A + Cortex-M systems, by an SPM mediated interface, e.g. partition to partition calls or, in general, through a mechanism which provides process separation between the client and the service sides of the API. In this context, the client must always define the Mbed TLS config option MBEDTLS_PSA_CRYPTO_CLIENT, while the service must always have MBEDTLS_PSA_CRYPTO_SPM, mainly to avoid symbol clashing at link time between the library interface and the tfm_crypto_api.c interface. When there is a component on

the service side which is able to identify the client through an ID, it is recommended to also define MBEDTLS_PSA_CRYPTO_KEY_ID_ENCODES_OWNER option in order to provide separation in the key space.

Usage of Mbed TLS configuration headers

Mbed TLS uses two different configuration headers, specified through the setting of the MBEDTLS_CONFIG_FILE, i.e. Mbed TLS config, and the setting of MBEDTLS_PSA_CRYPTO_CONFIG_FILE, i.e. the PSA configuration. In order to be able to perform header inclusion for psa/crypto.h, the configuration files must be visible to the compilation unit through the include hierarchy. If none of the macros are defined, the fall back strategy is to include the default config files available in the Mbed TLS repo, i.e. include/mbedtls/mbedtls_config.h and include/psa/crypto_config.h, which contain a set of default values for the macros.

Usage of the default header config when using the TF-M Crypto service is highly discouraged, mainly because both on the client side and on the service side a set of options must always be defined (or undefined), as described in the previous section. TF-M provides example _profiles_ which show the options and how they should be used on both client and service side of the integration. Note that to avoid falling back to the default PSA configuration, the Mbed TLS config file must always define the symbol MBEDTLS_PSA_CRYPTO_CONFIG. The symbol to enable the Mbed TLS config MBEDTLS_CONFIG_FILE instead must be available to the unit being compiled which is including psa/crypto.h, i.e. passed by the build system config stage.

Hardware acceleration

The TF-M Crypto partition must handle all HW related crypto tasks, if the platform is capable of offering hardware acceleration or if a complete Secure Element is present. The main difference between the two is that a hardware accelerator does not store keys but just accelerates operations, while a Secure Element is capable of storing keys and the PSA Crypto core running on the host must interface with it to store, retrieve or use them for crypto tasks, etc.

There are currently two methods to interface an accelerator into the Crypto service, and both rely on the Crypto partition fully owning the Crypto hardware, i.e. the memory mapped IO space must be bound the Crypto partition only. Both methods are implemented through the capability of the _backend_ library to either:

1. Provide a link time mechanism to replace pure SW implementations for algorithms with HW assisted implementations. In this case, the TF-M platform provides some additional HW abstraction through the usage of crypto_hw_accelerator_*() APIs. This is dubbed the *_ALT* approach and will be soon to be deprecated potentially starting from the release of Mbed TLS 4.0
2. Provide a cleanly defined interface specification[4] to describe the APIs that a driver must expose to the PSA Crypto core in order for the core to be able to offload operations to hardware. This is the preferred method for interfacing with HW.

Both solutions are currently handled at build time (either compilation or linking) by Mbed TLS. For details on how to integrate a driver please refer directly to the documentation referenced above and to the Mbed TLS repo.

Builtin keys

A particular driver using the interface described inPage 1168, 4 is the TF-M Builtin Key Loader driver[5]. The goal of the driver is to make Mbed TLS aware of *transparent builtin keys*, i.e. keys which can be read from the core (i.e. not fully opaque keys), but that are normally bound to the platform and provisioned in it, for which it would be more appropriate to treat them as standard

[4] PSA Unified Driver Interface for Cryptoprocessors: https://github.com/Mbed-TLS/mbedtls/blob/development/docs/proposed/psa-driver-interface.md

[5] TF-M Builtin Key Loader driver, normally described as *tfm_builtin_key_loader*

transparent keys. The concept of *transparent builtin keys* is not defined in the spec so it is specifically a non standard extension added by TF-M to the Mbed TLS implementation, which might be changed between releases until a standard solution is adopted. TF-M patches Mbed TLS on the fly to enable such behaviour using patches available in lib/ext/mbedcrypto. Implementations might disable the tfm_builtin_key_loader and then must provide their own alternative storage location for all of the TF-M required builtin keys, e.g. by having them stored in a Secure Element with a corresponding opaque driver.

Service API description

The Alloc and Init modules implement public APIs which are specific to the TF-M Crypto service, and are available only internally to other components of the TF-M Crypto partition. For a detailed description of the prototypes please refer to the tfm_crypto_api.h header.

Table 45: Init and Alloc modules APIs

Function	Module	Calle	Scope
tfm_cry	Init	SPM	Called during TF-M boot for initialisation. It does modules initialisation (it initializes the Alloc module) and initializes the *backend* library. Being the partition enabled for the SFN model, it does not implement any IPC specific message handler, instead it relies on the SPM being able to schedule SFN partitions using the SFN dispatcher with little overhead
tfm_cry	Init	SPM	Function to handle an SFN request or to interface with the message handler when running in IPC model
tfm_cry	Alloc	Init	Called by tfm_crypto_init(), it initialises the internal memory storage in the TF-M Crypto partition that the service uses to store multipart operation contexts as requested by clients.
tfm_cry	Alloc	Service modules	It allocates a new operation context for a multipart operation. It returns an handle to the allocated context in secure memory.
tfm_cry	Alloc	Service modules	It retrieves a previously allocated operation context of a multipart operation, based on the handle given as input.
tfm_cry	Alloc	Service modules	It releases a previously allocated operation context of a multipart operation, based on the handle given as input.
tfm_cry	*	Init	Interface functions called by the dispatcher to service PSA Crypto APIs requests

Configuration parameters

The TF-M Crypto service exposes some configuration parameters to tailor the service configuration in terms of supported functionalities and hence FLASH/RAM size to meet the requirements of different platforms and use cases. These parameters can be provided via CMake parameters during the CMake configuration step and as a configuration header to allow the configuration of the Mbed TLS library. When using Kconfig they are also exported in the Kconfig menus.

Table 46: Configuration parameters table

Parameter	Type	Description	Default
*CRYPTO_*	CMake build configuration parameter	Buffer used by Mbed TLS for its own allocations at runtime. This is a buffer allocated in static memory.	8096 (bytes)
*CRYPTO_*	CMake build configuration parameter	This parameter defines the maximum number of possible concurrent operation contexts (cipher, MAC, hash and key deriv) for multi-part operations, that can be allocated simultaneously at any time.	8
*CRYPTO_*	CMake build configuration parameter	This parameter applies only to IPC model builds. In IPC model, during a Service call, input and outputs are allocated temporarily in an internal scratch buffer whose size is determined by this parameter.	5120 (bytes)
*CRYPTO_*	CMake build configuration parameter	Defines the stack size assigned to the crypto partition in higher level of isolation configurations (L1 isolation has a common stack shared by all partitions)	6912 (bytes)
*CRYPTO_*	CMake build configuration parameter	Uses the Mbed TLS Crypto NV seed feature to provide entropy in case there is no HW acceleration providing HW entropy	Defined for platforms which don't have CRYPTO_HW_ACCELERATOR
*CRYPTO_*	CMake build configuration parameter	Defines the size of scratch buffers to handle input/outputs if the Memory Mapped IOVEC feature is not enabled	5120 (bytes)
*CRYPTO_*	CMake build configuration parameter	When enabled, only the multipart, i.e. non-integrated APIs will be available in the service	Not defined (Profile default)
*CRYPTO_*	CMake build configuration parameters	When enabled, the correspoding shim layer module and relative APIs are available in the service	Defined (Profile default)
MBEDTLS	Configuration header	The Mbed TLS library can be configured to support different algorithms through the usage of a configuration header file at build time. This allows for tailoring FLASH/RAM requirements for different platforms and use cases.	lib/ext/mbedcrypto/mbedcrypto_config/tfm_mbedcrypto_config_default.h (Profile default)
MBEDTLS	Configuration header	This header file specifies which cryptographic mechanisms are available through the PSA API when *MBEDTLS_PSA_CRYPTO_CONFIG* is enabled, and is not used when *MBEDTLS_PSA_CRYPTO_CONFIG* is disabled. Configuring TF-M always involves having the define enabled.	lib/ext/mbedcrypto/mbedcrypto_config/crypto_config_default.h (Profile default)

Symmetric key algorithm based Initial Attestation

Author

david.hu@arm.com

Introduction

This document proposes a design of symmetric key algorithm based Initial Attestation in TF-M.

Symmetric key algorithm based Initial Attestation (*symmetric Initial Attestation* for short) signs and verifies Initial Attestation Token (IAT) with a symmetric cryptography signature scheme, such as HMAC. It can reduce TF-M binary size and memory footprint on ultra-constrained devices without integrating asymmetric ciphers.

This proposal follows PSA Attestation API document[1].

Note: As pointed out by PSA Attestation API[Page 1171, 1], the use cases of Initial Attestation based on symmetric key algorithms can be limited due to the associated infrastructure costs for key management and operational complexities. It may also restrict the ability to interoperate with scenarios that involve third parties.

Design overview

The symmetric Initial Attestation follows the existing IAT generation sequence for Initial Attestation based on asymmetric key algorithm (*asymmetric Initial Attestation* for short).

As Profile Small design[2] requests, a configuration flag SYMMETRIC_INITIAL_ATTESTATION selects symmetric initial attestation during build.

The top-level design is shown in *Overall design diagram* below.

Symmetric Initial Attestation adds its own implementations of some steps in IAT generation in Initial Attestation secure service. More details are covered in *IAT generation in Initial Attestation secure service*.

The interfaces and procedures of Initial Attestation secure service are not affected. Refer to Initial Attestation Service Integration Guide[3] for details of the implementation of Initial Attestation secure service.

Symmetric Initial Attestation invokes t_cose library to build up COSE_Mac0 structure. COSE_Mac0 support is added to t_cose library in TF-M since official t_cose hasn't supported COSE_Mac0 yet. The design of COSE_Mac0 support is covered in *COSE_Mac0 support in t_cose*.

Note: The COSE_Mac0 implementation in this proposal is a prototype only for Proof of Concept so far. It may be replaced after t_cose officially supports COSE_Mac0 message.

---

[1] PSA Attestation API 1.0 (ARM IHI 0085)
[2] *Trusted Firmware-M Profile Small Design*
[3] *Initial Attestation Service Integration Guide*

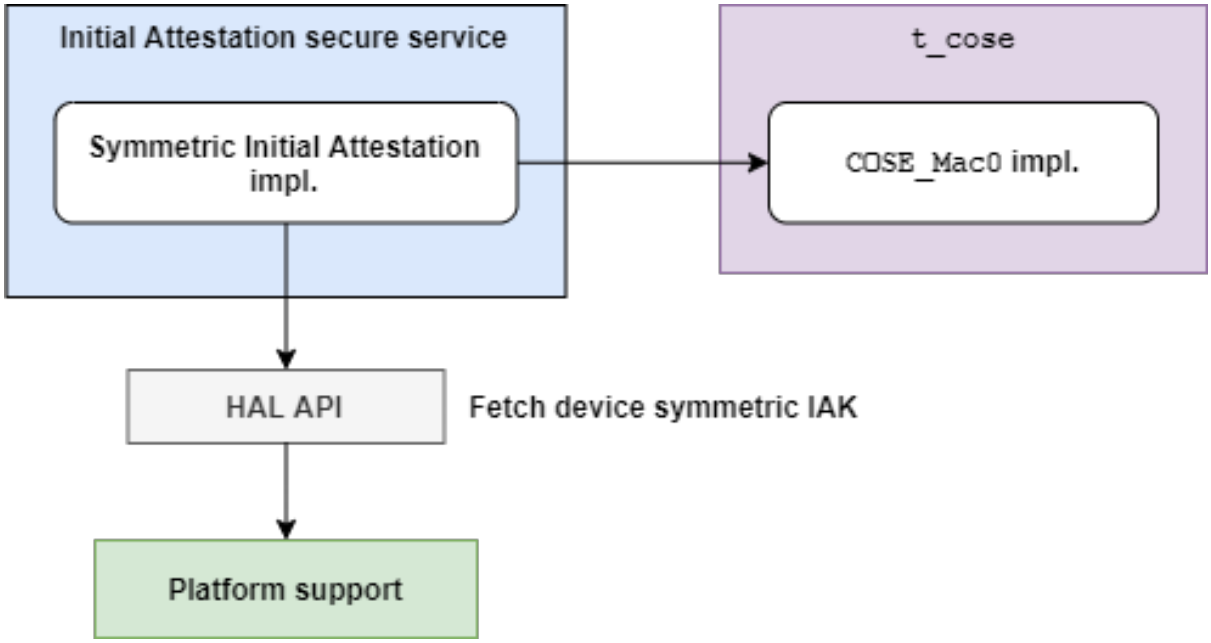

Fig. 13: Overall design diagram

Several HAL APIs are defined to fetch platform specific assets required by Symmetric Initial Attestation. For example, tfm_plat_get_symmetric_iak() fetches symmetric Initial Attestation Key (IAK). Those HAL APIs are summarized in *HAL APIs*.

Decoding and verification of symmetric Initial Attestation is also included in this proposal for regression test. The test suites and IAT decoding are discussed in *TF-M Test suite*.

QCBOR library and Crypto service are also invoked. But this proposal doesn't require any modification to either QCBOR or Crypto service. Therefore, descriptions of QCBOR and Crypto service are skipped in this document.

IAT generation in Initial Attestation secure service

The sequence of IAT generation of symmetric Initial Attestation is shown in *Symmetric IAT generation flow in Initial Attestation secure service* below. Note that the Register symmetric IAK stage is no longer required due to changes in the Crypto partition (attest_symmetric_key.c is now responsible only for calculating the instance ID).

In Initial Attestation secure service, symmetric Initial Attestation implements the following steps in attest_create_token(), which are different from those of asymmetric Initial Attestation.

- attest_token_start()
- Instance ID claims
- attest_token_finish()

If SYMMETRIC_INITIAL_ATTESTATION is selected, symmetric Initial Attestation dedicated implementations of those steps are included in build. Otherwise, asymmetric Initial Attestation dedicated implementations are included instead.

Symmetric Initial Attestation implementation resides a new file attest_symmetric_key.c to handle symmetric Instance ID related operations. Symmetric Initial Attestation dedicated attest_token_start() and attest_token_finish() are added in attestation_token.c.

The details are covered in following sections.

Symmetric Instance ID

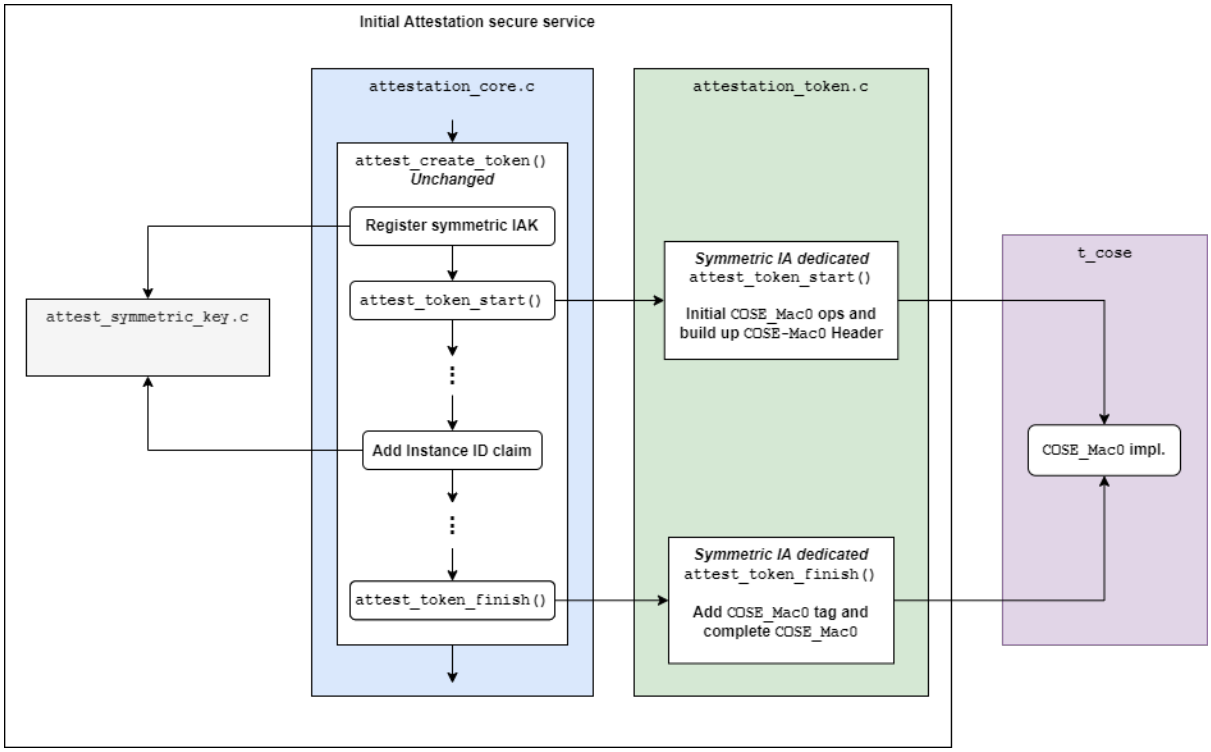

Fig. 14: Symmetric IAT generation flow in Initial Attestation secure service

Symmetric Initial Attestation dedicated attest_symmetric_key.c implements the attest_get_instance_id() function. This function returns the Instance ID value, calculating it if it has not already been calculated. Refer to *Instance ID claim_* for more details.

Note: Only symmetric IAK for HMAC algorithm is allowed so far.

Instance ID calculation

In symmetric Initial Attestation, Instance ID is also calculated the first time it is requested. It can protect critical symmetric IAK from being frequently fetched, which increases the risk of asset disclosure.

The Instance ID value is the output of hashing symmetric IAK raw data *twice*, as requested in PSA Attestation API[1]. HMAC-SHA256 may be hard-coded as the hash algorithm of Instance ID calculation.

Note: According to RFC2104[4], if a HMAC key is longer than the HMAC block size, the key will be first hashed. The hash output is used as the key in HMAC computation.

In current design, HMAC is used to calculate the authentication tag of COSE_Mac0. Assume that symmetric IAK is longer than HMAC block size (HMAC-SHA256 by default), the Instance ID is actually the HMAC key for COSE_Mac0 authentication tag generation, if Instance ID value is the output of hashing IAK only *once*. Therefore, attackers may request an valid IAT from device and fake malicious ones by using Instance ID to calculate valid authentication tags, to cheat others.

As a result, symmetric IAK raw data should be hashed *twice* to generate the Instance ID value.

The Instance ID calculation result is stored in a static buffer. Token generation process can call attest_get_instance_id() to fetch the data from that static buffer.

[4] HMAC: Keyed-Hashing for Message Authentication

attest_token_start()

Symmetric Initial Attestation dedicated attest_token_start() initializes the COSE_Mac0 signing context and builds up the COSE_Mac0 Header.

The workflow inside attest_token_start() is shown in *Workflow in symmetric Initial Attestation attest_token_start()* below.

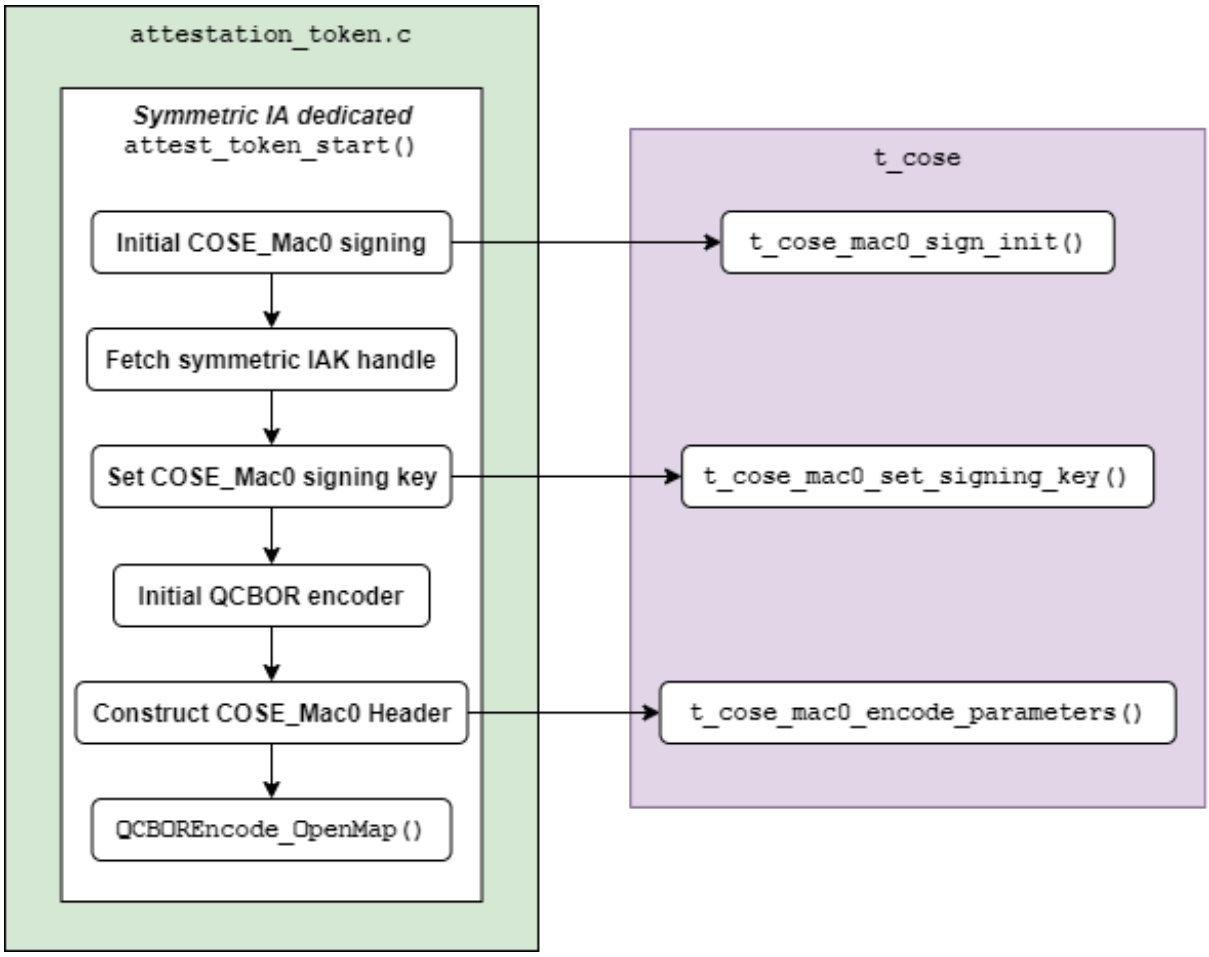

Fig. 15: Workflow in symmetric Initial Attestation attest_token_start()

Descriptions of each step are listed below:

1. t_cose_mac0_sign_init() is invoked to initialize COSE_Mac0 signing context in t_cose.
2. The symmetric IAK handle is set into COSE_Mac0 signing context via t_cose_mac0_set_signing_key().
3. Initialize QCBOR encoder.
4. The header parameters are encoded into COSE_Mac0 structure in t_cose_mac0_encode_parameters().
5. QCBOREncode_OpenMap() prepares for encoding the COSE_Mac0 payload, which is filled with IAT claims.

All the COSE_Mac0 functionalities in t_cose are covered in *COSE_Mac0 support in t_cose*.

Instance ID claim

Symmetric Initial Attestation also implements Instance ID claims in attest_add_instance_id_claim().

The Instance ID value is fetched via attest_get_instance_id(). The value has already been calculated during symmetric IAK registration. See *Instance ID calculation* for details.

The other steps are the same as those in asymmetric Initial Attestation implementation. The UEID type byte is set to 0x01.

attest_token_finish()

Symmetric Initial Attestation dedicated attest_token_finish() calls t_cose_mac0_encode_tag() to calculate and encode the authentication tag of COSE_Mac0 structure.

The whole COSE and CBOR encoding are completed in attest_token_finish().

The simplified flow in attest_token_finish() is shown in *Workflow in symmetric Initial Attestation attest_token_finish()* below.

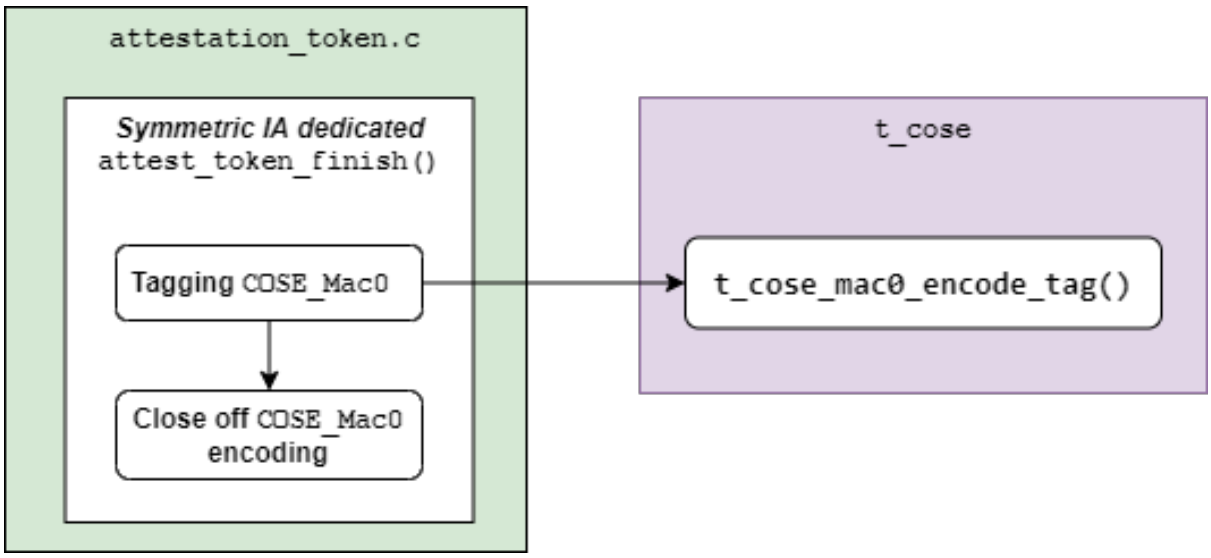

Fig. 16: Workflow in symmetric Initial Attestation attest_token_finish()

COSE_Mac0 support in t_cose

COSE_Mac0 supports in t_cose in TF-M include the following major functionalities:

- Encoding COSE_Mac0 structure
- Decoding and verifying COSE_Mac0 structure
- HMAC computation to generate and verify authentication tag
- Short-circuit tagging for test mode

According to RFC8152[5], COSE_Mac0 and COSE_Sign1 have similar structures. Therefore, the prototype follows COSE_Sign1 implementation to build up COSE_Mac0 file structure and implement COSE_Mac0 encoding and decoding.

Although COSE_Mac0 can share lots of data types, APIs and encoding/decoding steps with COSE_Sign1 in implementation, this prototype separates COSE_Mac0 implementation from COSE_Sign1. COSE_Mac0 owns its dedicated signing/verification contexts, APIs and encoding/decoding process. The purposes of separating COSE_Mac0 and COSE_Sign1 are listed below

- It can keep changes to COSE_Sign1 as small as possible and avoid conflicts with development in COSE_Sign1`. It can decrease conflicts if t_cose in TF-M is synchronized with original t_cose repository later.

[5] CBOR Object Signing and Encryption (COSE)

- COSE_Mac0 and COSE_Sign1 are exclusive in TF-M use cases. It cannot decrease TF-M memory footprint by extracting the common components shared by COSE_Mac0 and COSE_Sign1 but can make the design over-complicated.

Note: Only HMAC is supported in current COSE_Mac0 prototype.

File structure

New files are added to implement the functionalities listed above. The structure of files is shown in the table below.

Table 47: New files in t_cose

Directory	Files	Descriptions
src	t_cose_mac0_sig c	Encode COSE_Mac0 structure
	t_cose_mac0_ve c	Decode and verify COSE_Mac0 structure.
inc	t_cose_mac0_sig h	Data type definitions and function declarations of encoding and signing COSE_Mac0 message.
	t_cose_mac0_ve h	Data type definitions and function declarations of verifying COSE_Mac0 message.

Other t_cose files may also be changed to add COSE_Mac0 associated data types and function declarations.

HMAC operations are added in crypto_adapters/t_cose_psa_crypto.c. Preprocessor flags are added to select corresponding crypto for COSE message signing and verification.

- T_COSE_ENABLE_SIGN1 selects ECDSA and Hash operations for COSE_Sign1.
- T_COSE_ENABLE_MAC0 selects HMAC operations for COSE_Mac0.

Encoding COSE_Mac0

Following COSE_Sign1 implementation, COSE_Mac0 encoding exports similar functions to Initial Attestation secure service. The major functions are listed below.

Initialize signing context

t_cose_mac0_sign_init() initializes COSE_Mac0 signing context and configures option flags and algorithm used in signing.

```
static void
t_cose_mac0_sign_init(struct t_cose_mac0_sign_ctx *me,
                      int32_t                     option_flags,
                      int32_t                     cose_algorithm_id);
```

The COSE_Mac0 signing context is defined as

```
struct t_cose_mac0_sign_ctx {
   /* Private data structure */
   uint8_t              protected_parameters_buffer[
                          T_COSE_MAC0_MAX_SIZE_PROTECTED_PARAMETERS];
   struct q_useful_buf_c protected_parameters; /* The encoded protected parameters */
   int32_t              cose_algorithm_id;
   struct t_cose_key    signing_key;
```

(continues on next page)

(continued from previous page)

```
    int32_t                 option_flags;
    struct q_useful_buf_c kid;
    ...
};
```

Set signing key

t_cose_mac0_set_signing_key() sets the key used in COSE_Mac0 signing. Optional kid, as a key identifer, will be encoded into COSE_Mac0 Header unprotected bucket.

```
static void
t_cose_mac0_set_signing_key(struct t_cose_mac0_sign_ctx *me,
                            struct t_cose_key            signing_key,
                            struct q_useful_buf_c        kid);
```

Encode Header parameters

t_cose_mac0_encode_parameters() encodes the COSE_Mac0 Header parameters and outputs the encoded context to cbor_encode_ctx.

```
enum t_cose_err_t
t_cose_mac0_encode_parameters(struct t_cose_mac0_sign_ctx *context,
                              QCBOREncodeContext          *cbor_encode_ctx);
```

Calculate and add authentication tag

t_cose_mac0_encode_tag() calculates the authentication tag and finishes the COSE_Mac0 message.

```
enum t_cose_err_t
t_cose_mac0_encode_tag(struct t_cose_mac0_sign_ctx *context,
                       QCBOREncodeContext          *cbor_encode_ctx);
```

Decoding COSE_Mac0

Following COSE_Sign1 implementation, COSE_Mac0 decoding exports similar functions to test suite of Initial Attestation. The major functions are listed below.

Initialize verification context

t_cose_mac0_verify_init() initializes COSE_Mac0 verification context and configures option flags in verification.

```
static void
t_cose_mac0_verify_init(struct t_cose_mac0_verify_ctx *context,
                        int32_t                        option_flags);
```

The COSE_Mac0 verification context is defined as

```
struct t_cose_mac0_verify_ctx {
    /* Private data structure */
    struct t_cose_key      verification_key;
    int32_t                option_flags;
};
```

Set verification key

t_cose_mac0_set_verify_key() sets the key for verifying COSE_Mac0 authentication tag.

```
static void
t_cose_mac0_set_verify_key(struct t_cose_mac0_verify_ctx *context,
                           struct t_cose_key              verify_key);
```

Decode and verify COSE_Mac0

t_cose_mac0_verify() decodes the COSE_Mac0 structure and verifies the authentication tag.

```
enum t_cose_err_t
t_cose_mac0_verify(struct t_cose_mac0_verify_ctx *context,
                   struct q_useful_buf_c          cose_mac0,
                   struct q_useful_buf_c         *payload,
                   struct t_cose_parameters      *parameters);
```

Short-circuit tagging

If T_COSE_OPT_SHORT_CIRCUIT_TAG option is enabled, COSE_Mac0 encoding will hash the COSE_Mac0 content and add the hash output as an authentication tag. It is useful when critical symmetric IAK is unavailable or cannot be accessed, perhaps because it has not been provisioned or configured for the particular device. It is only for test and must not be used in actual use case. The kid parameter will either be skipped in COSE_Mac0 Header.

If T_COSE_OPT_ALLOW_SHORT_CIRCUIT option is enabled, COSE_Mac0 decoding will only verify the hash output, without requiring symmetric key for authentication tag verification.

TF-M Test suite

Symmetric Initial Attestation adds dedicated non-secure and secure test suites. The test suites also follow asymmetric Initial Attestation test suites implementation but optimize the memory footprint. Symmetric Initial Attestation non-secure and secure test suites request Initial Attestation secure service to generate IATs. After IATs are generated successfully, test suites decode IATs and parse the claims. Secure test suite also verifies the authentication tag in COSE_Mac0 structure.

Symmetric Initial Attestation implements its dedicated attest_token_decode_validate_token() in attest_symmetric_iat_decoded.c to perform IAT decoding required by test suites. If SYMMETRIC_INITIAL_ATTESTATION is selected, attest_symmetric_iat_decoded.c is included in build. Otherwise, asymmetric Initial Attestation dedicated implementations are included instead.

The workflow of symmetric Initial Attestation dedicated attest_token_decode_validate_token() is shown below.

If the decoding is required from secure test suite, attest_token_decode_validate_token() will fetch symmetric IAK to verify the authentication tag in COSE_Mac0 structure. If the decoding is required from non-secure test suite, attest_token_decode_validate_token() will decode COSE_Mac0 only by setting T_COSE_OPT_DECODE_ONLY option flag. Non-secure must not access the symmetric IAK.

HAL APIs

HAL APIs are summarized below.

Fetch device symmetric IAK

tfm_plat_get_symmetric_iak() fetches device symmetric IAK.

```
enum tfm_plat_err_t tfm_plat_get_symmetric_iak(uint8_t *key_buf,
                                               size_t buf_len,
                                               size_t *key_len,
                                               psa_algorithm_t *key_alg);
```

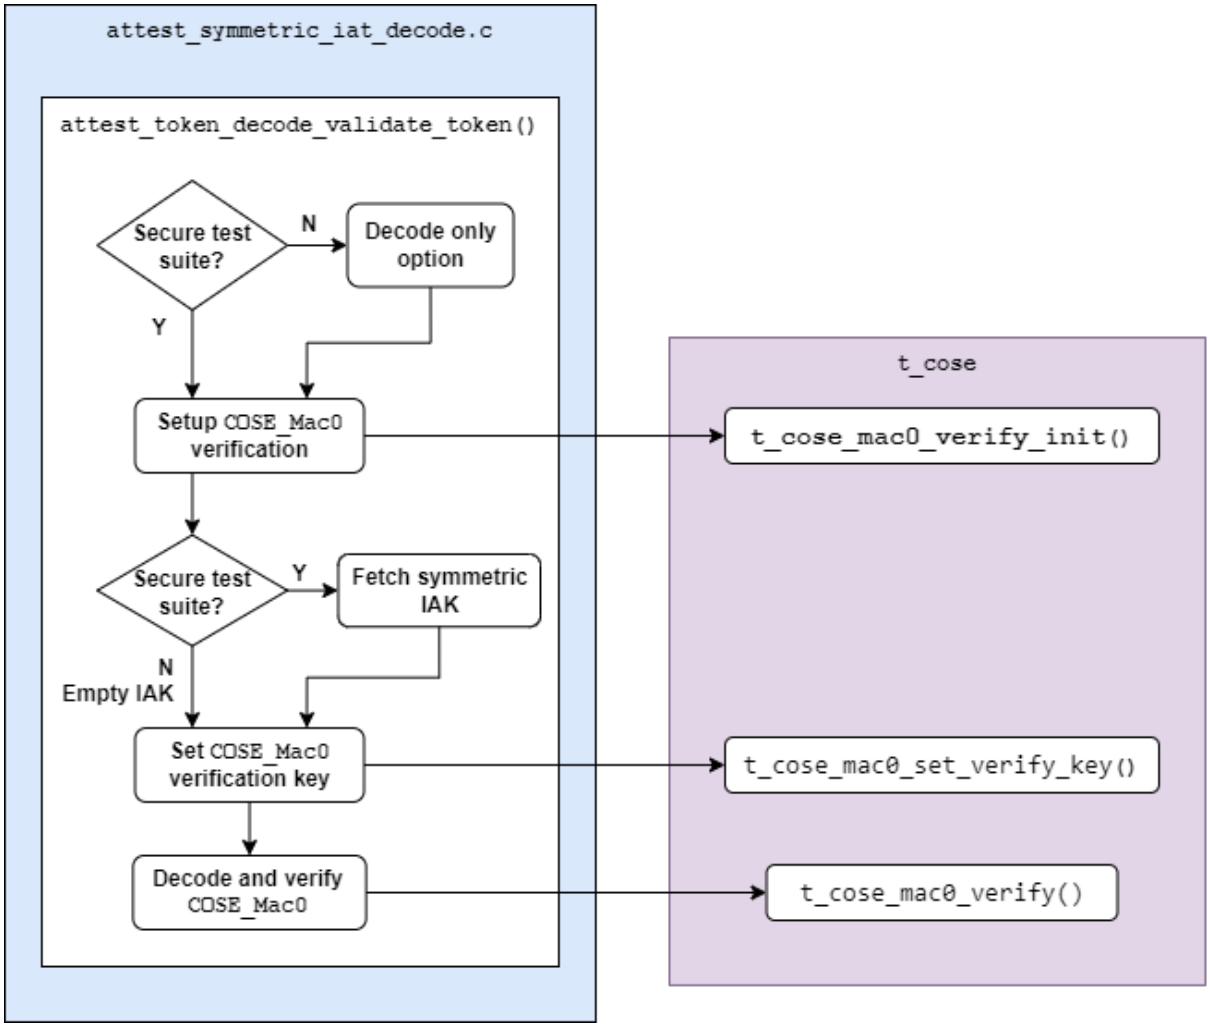

Fig. 17: Workflow in symmetric Initial Attestation attest_token_decode_validate_token()

Parameters:

key_buf	Buffer to store the symmetric IAK.
buf_len	The length of key_buf.
key_len	The length of the symmetric IAK.
key_alg	The key algorithm. Only HMAC SHA-256 is supported so far.

It returns error code specified in enum tfm_plat_err_t.

Get symmetric IAK key identifier

attest_plat_get_symmetric_iak_id() gets the key identifier of the symmetric IAK as the kid parameter in COSE Header.

Optional if device doesn't install a key identifier for symmetric IAK.

```
enum tfm_plat_err_t attest_plat_get_symmetric_iak_id(void *kid_buf,
                                                     size_t buf_len,
                                                     size_t *kid_len);
```

Parameters:

kid_buf	Buffer to store the IAK identifier.
buf_len	The length of kid_buf.
kid_len	The length of the IAK identifier.

It returns error code specified in enum tfm_plat_err_t.

Add support for block-aligned flash in Internal Trusted Storage

Author
Minos Galanakis

Organization
Arm Limited

Contact
Minos Galanakis <minos.galanakis@arm.com>

Abstract

The proposal is describing a mechanism to enable the use of larger flash devices, imposing a requirement for word-aligned full-block program operations, in Trusted Firmware-M.

Requirements

- Allow page-aligned writes for up to 512 Bytes per page.
- Guarantee data integrity and power-failure reliability.
- Do not alter existing supported platform behaviour.

Current implementation

In the current ITS filesystem design, each filesystem create or write operation requires two flash blocks to be updated: first the data block and then the metadata block. Buffering is avoided as much as possible to reduce RAM requirements.

However, if the ITS_FLASH_PROGRAM_UNIT is 512 Bytes then the data will have to stored in a temporary memory location in order to be able to write that much data in one-shot.

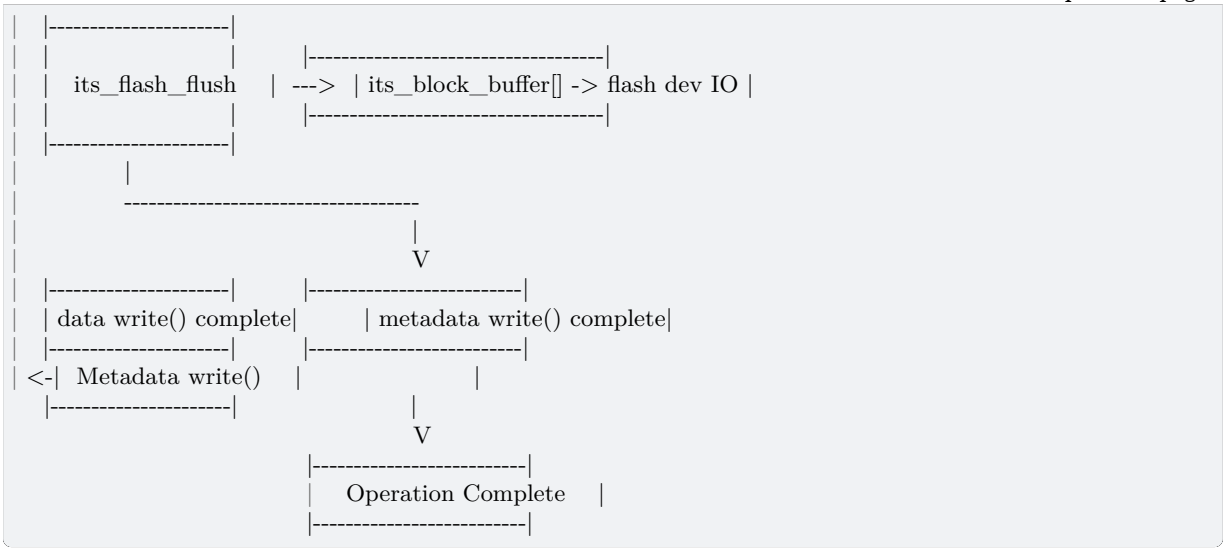
Proposed implementation overview

1. A new block-sized static buffer should be added to its_flash.c when ITS_FLASH_PROGRAM_UNIT is larger than currently supported.
2. Methods calling the flash API such as its_flash_write() or its_flash_block_to_block_move() will populate the buffer instead of directly programming the flash.
3. A new method its_flash_flush(), should be provided in order to flush the block buffer to the device.
4. its_flash_flush() should be called twice: Once after a data block update and once more after the metadata block update is completed.
5. The proposed design should require that the data block update is always completed before the metadata block update starts
6. Writes to the block buffer should be atomic, and guarded against corruption by data from different blocks.

Considerations

- The proposed implementation will increase the RAM usage of ITS by the size of a block, only for platforms which require block-aligned writes.
- Currently power-failure is detected by software by incrementing an 8-bit metadata header field (swap_count), as the last written byte. When the proposed block-buffer is used, the block is programmed in one-shot and the order the bytes are written on the physical device, is hardware dependent.
- A set of guarantees are required by the supported flash ECC devices. The device's flash APIs should provide a mechanism to capture and raise incomplete program operations, as well as write bytes in a sequential order.

For example, if a board powers down through a 512 page program operation, the next read operation should return an error rather than read invalid data.



Functional flow diagram

The logic of the proposal is described in the following diagram

```
   |----------------------|
   |  data write()        |
   |----------------------|
   |                      |       |------------------------------|
|-> |  its_flash_write   |    --->  | data[] -> its_block_buffer[] |
|   |                      |       |------------------------------|
```

PSA Internal Trusted Storage

PSA Internal Trusted Storage (ITS) is a PSA RoT Service for storing the most security-critical device data (e.g. cryptographic keys) in internal storage, which is trusted to provide data confidentiality and authenticity. This contrasts with PSA Protected Storage, which is an Application RoT service that allows larger data sets to be stored securely in external flash, with the option for encryption, authentication and rollback protection to protect the data-at-rest.

Current TF-M Secure Storage

Currently, the TF-M Secure Storage service implements PSA Protected Storage version 1.0-beta2. There is not yet an implementation of PSA Internal Trusted Storage in TF-M.

New TF-M service

The proposal is to implement the *PSA Internal Trusted Storage API* with the *TF-M Internal Trusted Storage service*. It can be abbreviated to *TF-M ITS service* in general and to `its` in code. This name has the advantage of making clear the correspondence between the service and the API it implements.

If this name is adopted, then it may make sense to rename the *Secure Storage service* to the *Protected Storage service* in the future to match. Then "secure storage" could refer to the two services as a collective.

The TF-M ITS service will implement PSA ITS version 1.0. It will be provided by a separate partition to Protected Storage, for a couple of reasons:

- To permit isolation between the services.
  - ITS is a PSA RoT Service, while Protected Storage is an Application RoT Service.
- To avoid circular dependencies.
  - The PSA Firmware Framework does not permit circular dependencies between partitions, which would occur if Protected Storage and ITS were provided by the same partition. Protected Storage depends on Crypto, which in turn depends on ITS.

The existing SST filesystem will be reused to provide the backend of the service, with the flash layer modified to direct storage to internal flash, rather than external.

Compared to Protected Storage, encryption, authentication and rollback protection are not required, so the SST encrypted object layer and the crypto and NV counter interfaces are not required. The rollback protection feature of the object table is also not required.

Code structure

The code structure of the service will be as follows:

TF-M repo:

interface/

- include/psa/internal_trusted_storage.h - PSA ITS API
- src/tfm_its_api.c - PSA ITS API implementation for NSPE

secure_fw/ns_callable/tfm_veneers.c - ITS veneers (auto-generated from manifest)

secure_fw/partitions/internal_trusted_storage/

- tfm_internal_trusted_storage.yaml - Partition manifest
- tfm_its_secure_api.c - PSA ITS API implementation for SPE
- tfm_its_req_mngr.c - Uniform secure functions and IPC request handlers
- tfm_internal_trusted_storage.h - TF-M ITS API (with client_id parameter)
- tfm_internal_trusted_storage.c - TF-M ITS implementation, using the flash_fs as a backend
- its_crypto_interface.h - APIs for encrypting ITS assets used by ITS implementation (optional)
- its_crypto_interface.c - Implementation for ITS encryption (optional)
- platform/ext/target/.../tfm_hal_its_encryption.c - Platform implementation for ITS encryption HAL APIs (optional)
- flash_fs/ - Filesystem
- flash/ - Flash interface

tf-m-tests repo:

test/secure_fw/suites/its/

- non_secure/psa_its_ns_interface_testsuite.c - Non-secure interface tests
- secure/psa_its_s_interface_testsuite.c - Secure interface tests

TF-M ITS implementation

The following APIs will be exposed by tfm_internal_trusted_storage.h:

```
psa_status_t tfm_its_init(void);

psa_status_t tfm_its_set(int32_t client_id,
                         psa_storage_uid_t uid,
                         size_t data_length,
                         const void *p_data,
                         psa_storage_create_flags_t create_flags);

psa_status_t tfm_its_get(int32_t client_id,
                         psa_storage_uid_t uid,
                         size_t data_offset,
                         size_t data_size,
                         void *p_data,
                         size_t *p_data_length);

psa_status_t tfm_its_get_info(int32_t client_id,
```

(continues on next page)

(continued from previous page)

```
                          psa_storage_uid_t uid,
                          struct psa_storage_info_t *p_info);

psa_status_t tfm_its_remove(int32_t client_id,
                            psa_storage_uid_t uid);
```

That is, the TF-M ITS APIs will have the same prototypes as the PSA ITS APIs, but with the addition of a client_id parameter, which will be passed from the ITS request manager. A tfm_its_init function will also be present, which will be called at initialisation time and not exposed through a veneer or SID.

The implementation in tfm_internal_trusted_storage.c must validate the parameters (excepting memory references, which are validated by the SPM), translate the UID and client ID into a file ID and then make appropriate calls to the filesystem layer. It must also take care ensure that any PSA Storage flags associated with the UID are honoured.

Filesystem

The ITS filesystem will be copied and modified from the SST filesystem. The modifications required will be to rename symbols from sst to its and to update the implementation to be aligned with the latest version of the PSA Storage spec (which consists mainly of moving to the psa_status_t error type and using common error codes from psa/error.h).

The filesystem will also be modified to align the size of each file stored to the alignment requirement exposed by the flash interface, by adding appropriate padding.

The filesystem code will be de-duplicated again once the ITS service is implemented (see below).

Flash layer

The flash layer will be copied from SST, and modified to direct writes to the internal flash device. It too needs to be updated to use psa_status_t error types.

Platform layer

The TF-M platform layer must be be updated to distinguish between the external flash device used for Protected Storage and internal flash device used for ITS. A flash region for the relevant storage service needs to be allocated in each.

On test platforms these may just be two distinct regions of the same flash device, but in general they will separate devices with their own drivers.

Detailed design considerations

Mapping UID onto file ID

The ITS APIs identify assets with 64-bit UIDs, to which the ITS service must append the 32-bit client ID of the calling partition for access control. The existing filesystem uses 32-bit file IDs to identify files, so some mapping would be required to convert between the identifiers.

SST uses the object table to do the mapping from client ID, UID pairs to file IDs, which means making an extra filesystem read/write for each get/set operation. This mapping has minimal overhead for SST though, because object table lookups are already required for rollback protection.

For ITS, no rollback protection feature is required, so there are two options:

- Keep a simplified version of the SST object table that just maps from (client ID, UID) to file ID

- Modify the filesystem to take (at least) 96-bit file IDs, in the form of a fixed-length char buffer.

The advantage of the former is that it would require no extra modification to the existing filesystem code, and the existing SST object table could be cut down for ITS. However, it would mean that every ITS request would invoke twice the number of filesystem operations, increasing latency and flash wear. The code size of the ITS partition would be increased, as would RAM usage as the table would need to be read into RAM.

The latter option would make the filesystem slightly more complex: the size of a metadata entry would be increased by 64-bits and the 96-bit fids would need to be copied and compared with memcpy and memcmp calls. On the other hand, mapping onto file IDs would incur only the cost of copying the UID and client ID values into the file ID buffer.

A third, even more general, solution would be to use arbitrary-length null-terminated strings as the file IDs. This is the standard solution in full-featured filesystems, but we do not currently require this level of complexity in secure storage.

With this in mind, the proposed option is the second.

Storing create flags

The ITS APIs provide a 32-bit create_flags parameter, which contains bit flags that determine the properties of the stored data. Only one flag is currently defined for ITS: PSA_STORAGE_FLAG_WRITE_ONCE, which prevents a UID from being modified or deleted after it is set for the first time.

There are two places that these flags could be stored: in the file data or as part of the file metadata.

For the first option, the ITS implementation would need to copy to the flags into the buffer containing the data, and adjust the size accordingly, for each set operation, and the reverse for each get. Every get_info operation would need to read some of the file data, rather than just the metadata, implying a second flash read. A potential downside is that many of the cryptographic assets stored in ITS will be aligned to power-of-two sizes; adding an extra 32-bits would misalign the size, which may reduce flash performance or necessitate adding padding to align to the flash page size.

To implement the second option, a 32-bit flag field would be added to the filesystem's metadata structure, whose interpretation is defined by the user. This field would clearly be catered towards the PSA Storage APIs, even if nominally generic, and alternative filesystems may not have any such field. However, it is a more intuitive solution and would simplify both flash alignment and get_info operations.

Overall, it seems more beneficial to store the flags in the metadata, so this is the proposed solution.

Code sharing between Protected Storage and ITS

To de-duplicate the filesystem code used by both Protected Storage and ITS, it is proposed that Protected Storage calls ITS APIs as its backend filesystem.

Protected Storage essentially becomes an encryption, authentication and rollback protection layer on top of ITS. It makes IPC requests or secure function calls to the ITS service to do filesystem operations on its behalf.

This has a couple of advantages:

- It shrinks Protected Storage's stack size, because the filesystem and flash layer stack is only in ITS.
- It automatically solves the problem of ensuring mutual exclusion in the filesystem and flash layers when Protected Storage and ITS are called concurrently. The second request to ITS will just be made to wait by the SPM.

The disadvantage of this approach is that it will increase the latency of Protected Storage requests, due to the extra overhead associated with making a second IPC request or secure function call. It also limits Protected Storage to using only the ITS APIs, unless extra veneers are added solely for Protected Storage to use. This, for example, prevents Protected Storage from doing partial writes to file without reading and re-writing the whole file.

ITS will need to be modified to direct calls from Protected Storage to a different flash device. It can use the client ID to detect when the caller is Protected Storage, and pass down the identity of the flash device to use to the flash layer, which then calls the appropriate driver.

An open question is what to do if Protected Storage itself wants to store something in internal storage in the future (e.g. rollback counters, hash tree/table or top hash). A couple of possible solutions would be:

- Divide up the UIDs, so certain UIDs from Protected Storage refer to assets in internal storage, and others to ones in external storage.
- Use the type field of psa_call in IPC model to distinguish between internal and external storage requests.

The other option for code sharing would be for Protected Storage and ITS to directly share filesystem code, which would be placed in a shared code region. With this approach, mutual exclusion to the flash device would need to be implemented separately, as would some way of isolating static memory belonging to each partition but not the code. Because of these complications, this option has not been considered further at this time.

Encryption in ITS

The ITS can optionally be configured to encrypt the internal trusted storage data. To support encryption in ITS the target platform must provide an implementation of the APIs defined in platform/include/tfm_hal_its_encryption.h:

```
enum tfm_hal_status_t tfm_hal_its_aead_generate_nonce(uint8_t *nonce,
                                                      const size_t nonce_size);

enum tfm_hal_status_t tfm_hal_its_aead_encrypt(
                                struct tfm_hal_its_auth_crypt_ctx *ctx,
                                const uint8_t *plaintext,
                                const size_t plaintext_size,
                                uint8_t *ciphertext,
                                const size_t ciphertext_size,
                                uint8_t *tag,
                                const size_t tag_size);

enum tfm_hal_status_t tfm_hal_its_aead_decrypt(
                                struct tfm_hal_its_auth_crypt_ctx *ctx,
                                const uint8_t *ciphertext,
                                const size_t ciphertext_size,
                                uint8_t *tag,
                                const size_t tag_size,
                                uint8_t *plaintext,
                                const size_t plaintext_size);
```

Then encryption can be enabled by setting the build option -DITS_ENCRYPTION=ON.

The figure fig-tfm_eits describes the encryption and decryption process happening when calling tfm_its_set and tfm_its_get.

By using an AEAD scheme, it is possible to not only encrypt the file data but also authenticate the file meta data, which include:

- File id
- File size

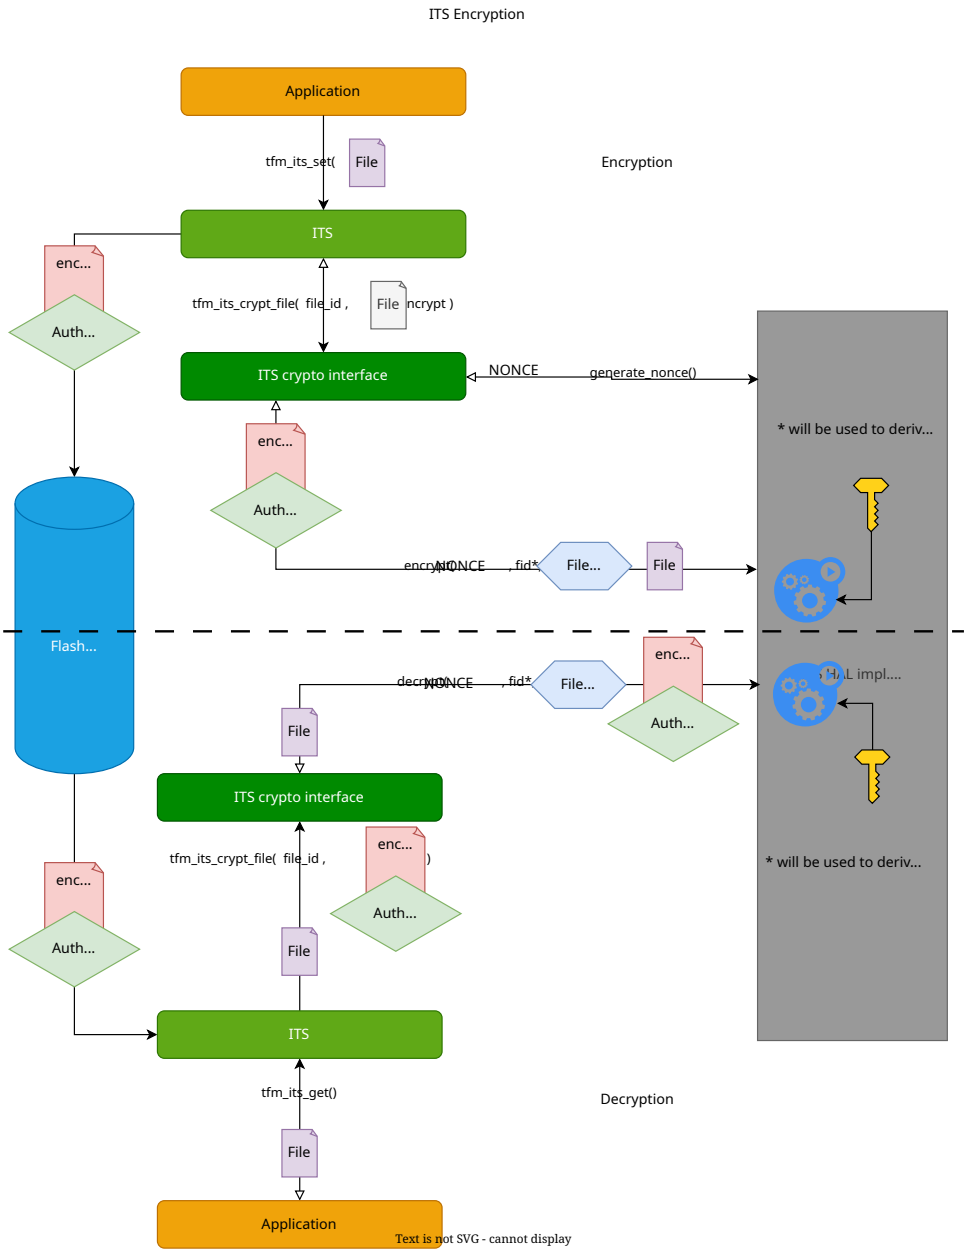

Fig. 18: En/Decryption of ITS

- File flags

The key used to perform the AEAD operation must be derived from a long-term key-derivation key and the file id, which is used as a derivation label. The long-term key-derivation key must be managed by the target platform.

There is a generic implementation of the abovementioned functions under platform/ext/common/template/tfm_hal_its_encryption.c using PSA crypto calls similar to Protected Storage solution. When used, the default NV seed template under platform/ext/common/template/crypto_nv_seed.c must be disabled, as it relies on ITS. If there is a need for NV seed usage, an ITS independent implementation is required. If NV seed is not necessary, it can be turned off by setting CRYPTO_NV_SEED=0.

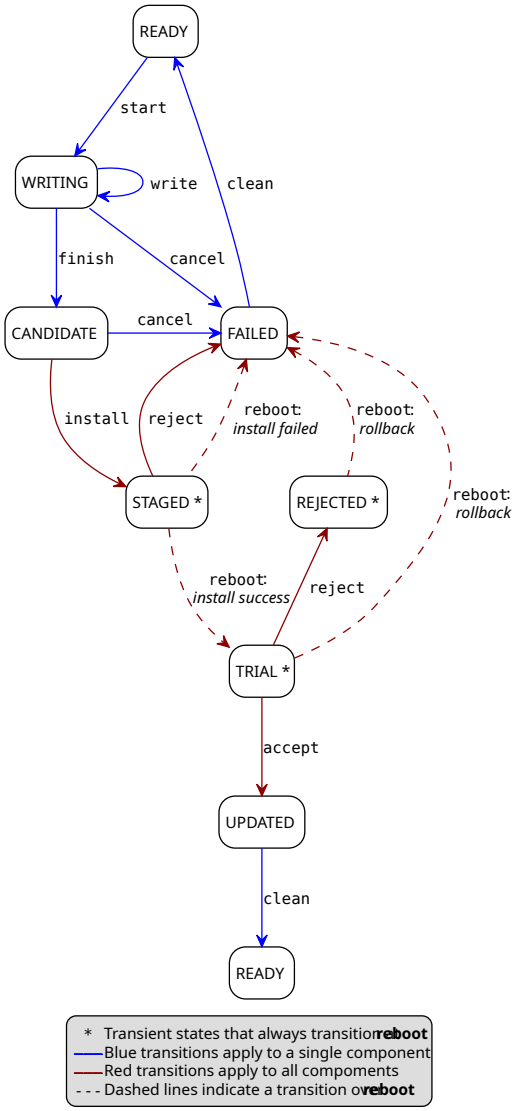
Introduction of Firmware Update service



The Firmware Update(FWU) service provides the functionality of updating firmware images. It provides a standard interface for updating firmware and it is platform independent. TF-M defines a shim layer to support cooperation between bootloader and FWU service.

This partition supports the following features:

- Query the firmware store information.

- Image preparation: prepare a new firmware image in the component's firmware store.
- Image installation: install prepared firmware images on all components that have been prepared for installation.
- Image trial: manage a trial of new firmware images atomically on all components that are in TRIAL state.

A typical flow through the component states is shown below[1].

Components

The structure of the TF-M Firmware Update service is listed below:

[1] PSA Firwmare Update API

Component name	Description	Location
Client API interface	This module exports the client API of PSA Firmware Update to the users.	./interface/src/tfm_fwu_api.c
Manifest	The manifest file is a description of the service components.	./secure_fw/partitions/firmware_update/tfm_firmware_update.yaml
NSPE client API interface	This module exports the client API of PSA Firmware Update to the NSPE(i.e. to the applications).	./interface/src/tfm_fwu_api.c
IPC request handlers	This module handles all the secure requests in IPC model. It maitains the image state context and calls the image ID converter to achieve the firmware update functionalities.	./secure_fw/partitions/firmware_update/tfm_fwu_req_mngr.c
Shim layer between FWU and bootloader	This module provides the APIs with the functionality of operating the bootloader to cooperate with the Firmware Update service	./secure_fw/partitions/firmware_update/bootloader/tfm_bootloader_fwu_abstraction.h
Shim layer example based on MCUboot	This module is the implementation of the shim layer between FWU and bootloader based on MCUboot.	./secure_fw/partitions/firmware_update/bootloader/mcuboot/tfm_mcuboot_fwu.c

Service API description

This service follows the PSA Firmware Update API spec of version 1.0[Page 1189, 1]. Please refer to Firmware Update spec for the detailed description.

Shim Layer between FWU and bootloader

The firmware update operations are achieved by calling the shim layer APIs between bootloader and FWU.

Shim layer introduction

This shim layer provides the APIs with the functionality of operating the bootloader to cooperate with the Firmware Update service. This shim layer is decoupled from bootloader implementation. Users can specify a specific bootloader by setting TFM_FWU_BOOTLOADER_LIB build configuration and adding the specific build scripts into that file. By default, the MCUboot is chosen as the bootloader.

Interfaces of the shim Layer

fwu_bootloader_init(function)

Prototype

```
psa_status_t fwu_bootloader_init(void);
```

Description

Bootloader related initialization for the firmware update. It reads some necessary shared data from the memory if needed. It initializes the flash drivers defined in FLASH_DRIVER_LIST. Platform can define FLASH_DRIVER_LIST in flash_layout.h to overload the default driver list.

Parameters

N/A

fwu_bootloader_staging_area_init(function)

Prototype

```
psa_status_t fwu_bootloader_staging_area_init(psa_fwu_component_t component,
                                              const void *manifest,
                                              size_t manifest_size);
```

Description

The component is in READY state. Prepare the staging area of the component for image download. For example, initialize the staging area, open the flash area, and so on.

Parameters

- component: The identifier of the target component in bootloader.
- manifest: A pointer to a buffer containing a detached manifest for the update. If the manifest is bundled with the firmware image, manifest must be NULL.
- manifest_size: Size of the manifest buffer in bytes.

fwu_bootloader_load_image(function)

Prototype

```
psa_status_t fwu_bootloader_load_image(psa_fwu_component_t component,
                                       size_t       image_offset,
                                       const void    *block,
                                       size_t       block_size);
```

Description

Load the image into the target component.

Parameters

- component: The identifier of the target component in bootloader.
- image_offset: The offset of the image being passed into block, in bytes.
- block: A buffer containing a block of image data. This might be a complete image or a subset.
- block_size: Size of block.

fwu_bootloader_install_image(function)

Prototype

```
psa_status_t fwu_bootloader_install_image(psa_fwu_component_t *candidates,
                                          uint8_t number);
```

Description

Check the authenticity and integrity of the image. If a reboot is required to complete the check, then mark this image as a candidate so that the next time bootloader runs it will take this image as a candidate one to bootup. Return the error code PSA_SUCCESS_REBOOT.

Parameters

- candidates: A list of components in CANDIDATE state.
- number: Number of components in CANDIDATE state.

fwu_bootloader_mark_image_accepted(function)

Prototype

```
psa_status_t fwu_bootloader_mark_image_accepted(const psa_fwu_component_t *trials,
                                                uint8_t number);
```

Description

Call this API to mark the TRIAL(running) image in component as confirmed to avoid revert when next time bootup. Usually, this API is called after the running images have been verified as valid.

Parameters

- trials: A list of components in TRIAL state.
- number: Number of components in TRIAL state.

fwu_bootloader_reject_staged_image(function)

Prototype

```
psa_status_t fwu_bootloader_reject_staged_image(psa_fwu_component_t component);
```

Description

The component is in STAGED state. Call this API to Uninstall the staged image in the component so that this image will not be treated as a candidate next time bootup.

Parameters

- component: The identifier of the target component in bootloader.

fwu_bootloader_reject_trial_image(function)

Prototype

```
psa_status_t fwu_bootloader_reject_trial_image(psa_fwu_component_t component);
```

Description

The component is in TRIAL state. Mark the running image in the component as rejected.

Parameters

- component: The identifier of the target component in bootloader.

fwu_bootloader_clean_component(function)

Prototype

```
psa_status_t fwu_bootloader_clean_component(psa_fwu_component_t component);
```

Description

The component is in FAILED or UPDATED state. Clean the staging area of the component.

Parameters

- component: The identifier of the target component in bootloader.

fwu_bootloader_get_image_info(function)

Prototype

```
psa_status_t fwu_bootloader_get_image_info(psa_fwu_component_t component,
                                           bool query_state,
                                           bool query_impl_info,
                                           psa_fwu_component_info_t *info);
```

Description

Get the image information of the given bootloader_image_id in the staging area or the running area.

Parameters

- component: The identifier of the target component in bootloader.
- query_state: Whether query the 'state' field of psa_fwu_component_info_t.
- query_impl_info: Whether Query 'impl' field of psa_fwu_component_info_t.
- info: Buffer containing return the component information.

Additional shared data between BL2 and SPE

An additional TLV area "image version" is added into the shared memory between BL2 and TF-M. So that the firmware update partition can get the image version. Even though the image version information is also included in the BOOT RECORD TLV area which is encoded by CBOR, adding a dedicated image version TLV area is preferred to avoid involving the CBOR encoder which can increase the code size. The FWU partition will read the shared data at the partition initialization.

Build configurations related to FWU partition

- TFM_PARTITION_FIRMWARE_UPDATE Controls whether FWU partition is enabled or not.
- TFM_FWU_BOOTLOADER_LIB Bootloader configure file for FWU partition.
- TFM_CONFIG_FWU_MAX_WRITE_SIZE The maximum permitted size for block in psa_fwu_write, in bytes.
- TFM_FWU_BUF_SIZE Size of the FWU internal data transfer buffer (defaults to TFM_CONFIG_FWU_MAX_WRITE_SIZE if not set).
- FWU_STACK_SIZE The stack size of FWU Partition.
- FWU_DEVICE_CONFIG_FILE The device configuration file for FWU partition. The default value is the configuration file generated for MCUboot. The following macros should be defined in the configuration file:
  - FWU_COMPONENT_NUMBER The number of components on the device.

    Note: In this design, component ID ranges from 0 to FWU_COMPONENT_NUMBER - 1.

  - FWU_SUPPORT_TRIAL_STATE Whether TRIAL component state is supported.
- TEST_NS_FWU FWU nonsecure tests switch.
- TEST_S_FWU FWU secure tests switch.

Note: The running image which supports revert mechanism should be confirmed before initiating a firmware update process. For example, if the running image is built with -DMCUBOOT_UPGRADE_STRATEGY=SWAP_USING_MOVE, the image should be confirmed either by adding -DMCUBOOT_CONFIRM_IMAGE=ON build option or by calling psa_fwu_accept() API before initiating a firmware

update process. Otherwise, PSA_ERROR_BAD_STATE will be returned by psa_fwu_start().

Limitations of current implementation

Currently, the MCUboot based implementation does not record image update results like failure or success. And FWU partition does not detect failure errors in bootloader installation. If an image installation fails in the bootloader and the old image still runs after reboot, PSA_FWU_READY state will be returned by psa_fwu_query() after reboot.

Currently, image download recovery after a reboot is not supported. If a reboot happens in image preparation, the downloaded image data will be ignored after the reboot.

Benefits Analysis on this Partition

Implement the FWU functionality in the non-secure side

The APIs listed in PSA Firmware Update API spec[Page 1189, 1] can also be implemented in the non-secure side.

Pros and Cons for implementing FWU APIs in secure side

Pros

- It protects the image in the passive or staging area from being tampered with by the NSPE. Otherwise, a malicious actor from NSPE can tamper the image stored in the non-secure area to break image update.
- It protects secure image information from disclosure. In some cases, the non-secure side shall not be permitted to get secure image information.
- It protects the active image from being manipulated by NSPE. Some bootloader supports testing the image. After the image is successfully installed and starts to run, the user should set the image as permanent image if the image passes the test. To achieve this, the area of the active image needs to be accessed. In this case, implementing FWU service in SPE can prevent NSPE from manipulating the active image area.
- On some devices, such as the Arm Musca-B1 board, the passive or staging area is restricted as secure access only. In this case, the FWU partition should be implemented in the secure side.

Cons

- It increases the image size of the secure image.
- It increases the execution latency and footprint. Compared to implementing FWU in NSPE directly, calling the Firmware Update APIs which are implemented in the secure side increases the execution latency and footprint.
- It can increase the attack surface of the secure runtime.

Users can decide whether to call the FWU service in TF-M directly or implement the Firmware Update APIs in the non-secure side based on the pros and cons analysis above.

Protected Storage service key management

Author
Jamie Fox

Jamie Fox <jamie.fox@arm.com>

Background

The PSA Protected Storage API requires confidentiality for external storage to be provided by:

> **cryptographic ciphers using device-bound keys**, a tamper resistant enclosure, or an inaccessible deployment location, depending on the threat model of the deployed system.

A TBSA-M-compliant device must embed a Hardware Unique Key (HUK), which provides the root of trust (RoT) for confidentiality in the system. It must have at least 128 bits of entropy (and a 128 bit data size), and be accessible only to Trusted code or Trusted hardware that acts on behalf of Trusted code. [TBSA-M]

Design description

Each time the system boots, PS will request that the Crypto service uses a key derivation function (KDF) to derive a storage key from the HUK, by referring to the builtin key handle for the HUK. The storage key could be kept in on-chip volatile memory private to the Crypto partition, or it could remain inside a secure element. Either way it will not be returned to PS.

For each call to the PSA Protected Storage APIs, PS will make requests to the Crypto service to perform AEAD encryption and/or decryption operations using the storage key (providing a fresh nonce for each encryption).

At no point will PS access the key material itself, only referring to the HUK and storage key by their handles in the Crypto service.

Key derivation

PS will make key derivation requests to the Crypto service with calls to the PSA Crypto APIs. In order to derive the storage key, the following calls are required:

```
status = psa_key_derivation_setup(&op, PSA_ALG_HKDF(PSA_ALG_SHA_256));

/* Set up a key derivation operation with HUK  */
status = psa_key_derivation_input_key(&op, PSA_KEY_DERIVATION_INPUT_SECRET,
                                      TFM_BUILTIN_KEY_ID_HUK);

/* Supply the PS key label as an input to the key derivation */
status = psa_key_derivation_input_bytes(&op, PSA_KEY_DERIVATION_INPUT_INFO,
                                        key_label,
                                        key_label_len);

/* Create the storage key from the key derivation operation */
status = psa_key_derivation_output_key(&attributes, &op, &ps_key);
```

Note: TFM_BUILTIN_KEY_ID_HUK is a static key ID that is used to identify the HUK. It has an arbitrary value defined in tfm_crypto_defs.h

ps_key is a PSA Crypto key handle to a volatile key, set by the derivation operation. After the call to psa_key_derivation_output_key, it can be used to refer the storage key.

key_label can be any string that is independent of the input key material and different to the label used in any other derivation from the same input key. It prevents two different contexts from deriving the same output key from the same input key.

The key derivation function used by the crypto service to derive the storage key will be HKDF, with SHA-256 as the underlying hash function. HKDF is suitable because:

- It is simple and efficient, requiring only two HMAC operations when the length of the output key material is less than or equal to the hash length (as is the case here).
- The trade-off is that HKDF is only suitable when the input key material has at least as much entropy as required for the output key material. But this is the case here, as the HUK has 128 bits of entropy, the same as required by PS.
- HKDF is standardised in RFC 5869 [RFC5869] and its security has been formally analysed. [HKDF]
- It is supported by the TF-M Crypto service.

The choice of underlying hash function is fairly straightforward: it needs to be a modern standardised algorithm, considered to be secure and supported by TF-M Crypto. This narrows it down to just the SHA-2 family. Of the hash functions in the family, SHA-256 is the simplest and provides more than enough output length.

Keeping the storage key private to PS

The Crypto service derives a platform key from the HUK, using the partition ID as the input to that derivation, and that platform key is used for the key derivation by PS. This happens transparently, and to PS is indistinguishable from deriving from the HUK except that other partitions cannot derive the storage key even if they know the derivation parameters.

Key use

To encrypt and decrypt data, PS will call the PSA Crypto AEAD APIs in the same way as the current implementation, but ps_key will refer to the storage key, rather than the imported HUK. For each encryption operation, the following call is made (and analogously for decryption):

```
psa_aead_encrypt(ps_key, PS_CRYPTO_ALG,
                 crypto->ref.iv, PS_IV_LEN_BYTES,
                 add, add_len,
                 in, in_len,
                 out, out_size, out_len);
```

Software Design Notes

Code sharing between independently linked XIP binaries

Author
Tamas Ban

Organization
Arm Limited

Contact
tamas.ban@arm.com

Motivation

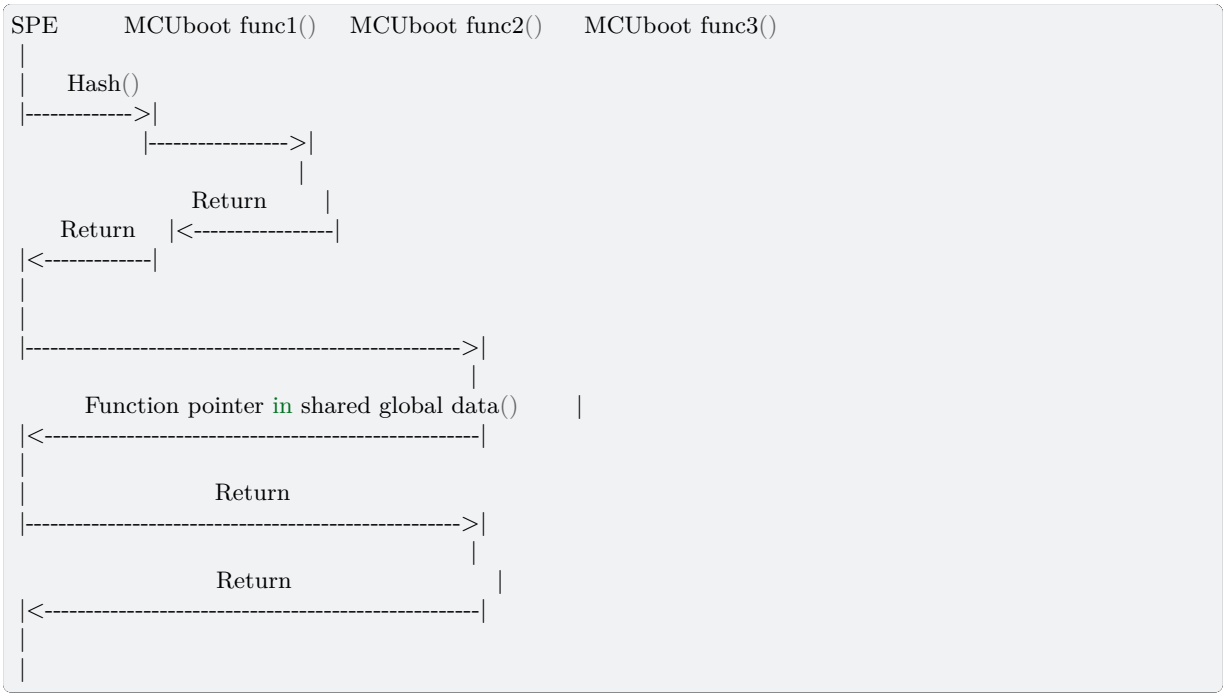
Cortex-M devices are usually constrained in terms of flash and RAM. Therefore, it is often challenging to fit bigger projects in the available memory. The PSA specifications require a device to both have a secure boot process in place at device boot-up time, and to have a partition in the SPE which provides cryptographic services at runtime. These two entities have some overlapping functionality. Some cryptographic primitives (e.g. hash calculation and digital signature verification) are required both in the bootloader and the runtime environment. In the current TF-M code base, both firmware components use the mbed-crypto library to implement these requirements. During the build process, the mbed-crpyto library is built twice, with different configurations (the bootloader requires less functionality) and then linked to the corresponding firmware component. As a result of this workflow, the same code is placed in the flash twice. For example, the code for the SHA-256 algorithm is included in MCUboot, but the exact same code is duplicated in the SPE cryptography partition. In most cases, there is no memory isolation between the bootloader and the SPE, because both are part of the PRoT code and run in the secure domain. So, in theory, the code of the common cryptographic algorithms could be reused among these firmware components. This could result in a big reduction in code footprint, because the cryptographic algorithms are usually flash hungry. Code size reduction can be a good opportunity for very constrained devices, which might need to use TF-M Profile Small anyway.

Technical challenge

Code sharing in a regular OS environment is easily achievable with dynamically linked libraries. However, this is not the case in Cortex-M systems where applications might run bare-metal, or on top of an RTOS, which usually lacks dynamic loading functionality. One major challenge to be solved in the Cortex-M space is how to share code between independently linked XIP applications that are tied to a certain memory address range to be executable and have absolute function and global data memory addresses. In this case, the code is not relocatable, and in most cases, there is no loader functionality in the system that can perform code relocation. Also, the lack of an MMU makes the address space flat, constant and not reconfigurable at runtime by privileged code.

One other difficulty is that the bootloader and the runtime use the same RAM area during execution. The runtime firmware is executed strictly after the bootloader, so normally, it can reuse the whole secure RAM area, as it would be the exclusive user. No attention needs to be paid as to where global data is placed by the linker. The bootloader does not need to retain its state. The low level startup of the runtime firmware can freely overwrite the RAM with its data without corrupting bootloader functionality. However, with code sharing between bootloader and runtime firmware, these statements are no longer true. Global variables used by the shared code must either retain their value or must be reinitialised during low level startup of the runtime firmware. The startup code is not allowed to overwrite the shared global variables with arbitrary data. The following design proposal provides a solution to these challenges.

Design concept



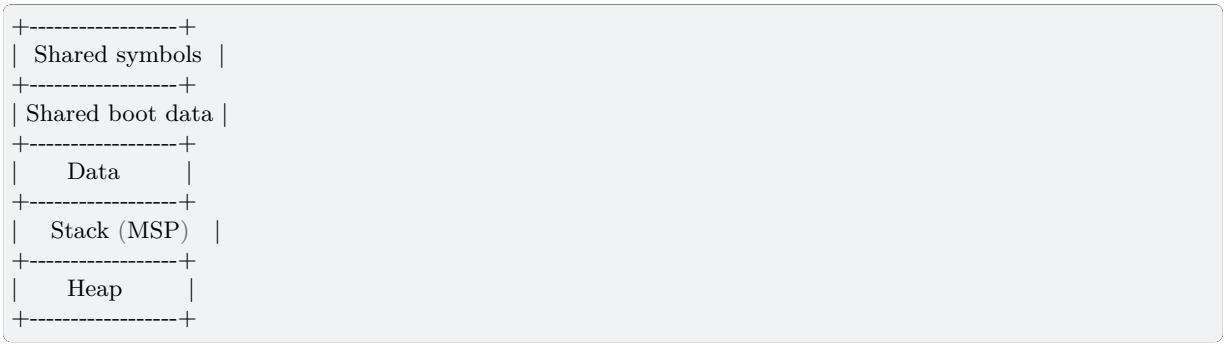
The bootloader is sometimes implemented as ROM code (BL1) or stored in a region of the flash which is lockable, to prevent tampering. In a secure system, the bootloader is immutable code and thus implements a part of the Root of Trust anchor in the device, which is trusted implicitly. The shared code is primarily part of the bootloader, and is reused by the runtime SPE firmware at a later stage. Not all of the bootloader code is reused by the runtime SPE, only some cryptographic functions.

Simplified steps of building with code sharing enabled:

- Complete the bootloader build process to have a final image that contains the absolute addresses of the shared functions, and the global variables used by these functions.

- Extract the addresses of the functions and related global variables that are intended to be shared from the bootloader executable.
- When building runtime firmware, provide the absolute addresses of the shared symbols to the linker, so that it can pick them up, instead of instantiating them again.

The execution flow looks like this:



The execution flow usually returns from a shared function back to the SPE with an ordinary function return. So usually, once a shared function is called in the call path, all further functions in the call chain will be shared as well. However, this is not always the case, as it is possible for a shared function to call a non-shared function in SPE code through a global function pointer.

For shared global variables, a dedicated data section must be allocated in the linker configuration file. This area must have the same memory address in both MCUboot's and the SPE's linker files, to ensure the integrity of the variables. For simplicity's sake, this section is placed at the very beginning of the RAM area. Also, the RAM wiping functionality at the end of the secure boot flow (that is intended to remove any possible secrets from the RAM) must not clear this area. Furthermore, it must be ensured that the linker places shared globals into this data section. There are two way to achieve this:

- Put a filter pattern in the section body that matches the shared global variables.
- Mark the global variables in the source code with special attribute *__attribute__((section(<NAME_OF_SHARED_SYMBOL_SECTION>)))*

RAM memory layout in MCUboot with code sharing enabled:

RAM memory layout in SPE with code sharing enabled:

```

+------------------+
|      Heap        |
+------------------+
```

Patching Mbed TLS

In order to share some global function pointers from mbed-crypto that are related to dynamic memory allocation, their scope must be extended from private to global. This is needed because some compiler toolchain only extract the addresses of public functions and global variables, and extraction of addresses is a requirement to share them among binaries. Therefore, a short patch was created for the mbed-crypto library, which "globalises" these function pointers:

lib/ext/mbedcrypto/0002-Enable-crypto-code-sharing-between-independent-binar.patch

The patch needs to be manually applied in the Mbed TLS repo, if code sharing is enabled. The patch has no effect on the functional behaviour of the cryptographic library, it only extends the scope of some variables.

Tools support

All the currently supported compilers provide a way to achieve the above objectives. However, there is no standard way, which means that the code sharing functionality must be implemented on a per compiler basis. The following steps are needed:

- Extraction of the addresses of all global symbols.
- The filtering out of the addresses of symbols that aren't shared. The goal is to not need to list all the shared symbols by name. Only a simple pattern has to be provided, which matches the beginning of the symbol's name. Matching symbols will be shared. Examples are in : *bl2/shared_symbol_template.txt*
- Provision of the addresses of shared symbols to the linker during the SPE build process.
- The resolution of symbol collisions during SPE linking. Because mbed-crypto is linked to both firmware components as a static library, the external shared symbols will conflict with the same symbols found within it. In order to prioritize the external symbol, the symbol with the same name in mbed-crypto must be marked as weak in the symbol table.

The above functionalities are implemented in the toolchain specific CMake files:

- *toolchain_ARMCLANG.cmake*

- *toolchain_GNUARM.cmake*

By the following two functions:

- *target_share_symbols()*: Extract and filter shared symbol addresses from MCUboot.
- *target_link_shared_code()*: Link shared code to the SPE and resolve symbol conflict issues.

ARMCLANG

The toolchain specific steps are:

- Extract all symbols from MCUboot: add *-symdefs* to the compiler command line
- Filter shared symbols: call CMake script *FilterSharedSymbols.cmake*
- Weaken duplicated (shared) symbols in the mbed-crypto static library that are linked to the SPE: *arm-none-eabi-objcopy*
- Link shared code to SPE: Add the filtered output of *-symdefs* to the SPE source file list.

GNUARM

The toolchain specific steps are:

- Extract all symbols from MCUboot: *arm-none-eabi-nm*
- Filter shared symbols: call CMake script: *FilterSharedSymbols.cmake*
- Strip unshared code from MCUboot: *arm-none-eabi-strip*
- Weaken duplicated (shared) symbols in the mbed-crypto static library that are linked to the SPE: *arm-none-eabi-objcopy*
- Link shared code to SPE: Add *-Wl -R <SHARED_STRIPPED_CODE.axf>* to the compiler command line

IAR

Functionality currently not implemented, but the toolchain supports doing it.

Memory footprint reduction

Build type: MinSizeRel Platform: mps2/an521 Version: TF-Mv1.2.0 + code sharing patches MCUboot image encryption support is disabled.

	ConfigDefault		ConfigProfile-M		ConfigProfile-S	
	ARM-CLANG	GNUARM	ARM-CLANG	GNUARM	ARM-CLANG	GNUARM
CODE_SHARING=OFI	122268	124572	75936	75996	50336	50224
CODE_SHARING=ON	113264	115500	70400	70336	48840	48988
Difference	9004	9072	5536	5660	1496	1236

If MCUboot image encryption support is enabled then saving could be up to ~13-15KB.

Note: Code sharing on Musca-B1 was tested only with SW only crypto, so crypto hardware acceleration must be turned off: -DCRYPTO_HW_ACCELERATOR=OFF

Useability considerations

Functions that only use local variables can be shared easily. However, functions that rely on global variables are a bit tricky. They can still be shared, but all global variables must be placed in the shared symbol section, to prevent overwriting and to enable the retention of their values.

Some global variables might need to be reinitialised to their original values by runtime firmware, if they have been used by the bootloader, but need to have their original value when runtime firmware starts to use them. If so, the reinitialising functionality must be implemented explicitly, because the low level startup code in the SPE does not initialise the shared variables, which means they retain their value after MCUboot stops running.

If a bug is discovered in the shared code, it cannot be fixed with a firmware upgrade, if the bootloader code is immutable. If this is the case, disabling code sharing might be a solution, as the new runtime firmware could contain the fixed code instead of relying on the unfixed shared code. However, this would increase code footprint.

API backward compatibility also can be an issue. If the API has changed in newer version of the shared code. Then new code cannot rely on the shared version. The changed code and all the other shared code where it is referenced from must be ignored and the updated version of the functions must be compiled in the SPE binary. The Mbed TLS library is API compatible with its current version (v2.24.0) since the mbedtls-2.7.0 release (2018-02-03).

To minimise the risk of incompatibility, use the same compiler flags to build both firmware components.

The artifacts of the shared code extraction steps must be preserved so as to remain available if new SPE firmware (that relies on shared code) is built and released. Those files are necessary to know the address of shared symbols when linking the SPE.

How to use code sharing?

Considering the above, code sharing is an optional feature, which is disabled by default. It can be enabled from the command line with a compile time switch:

- *TFM_CODE_SHARING*: Set to *ON* to enable code sharing.

With the default settings, only the common part of the mbed-crypto library is shared, between MCUboot and the SPE. However, there might be other device specific code (e.g. device drivers) that could be shared. The shared cryptography code consists mainly of the SHA-256 algorithm, the *bignum* library and some RSA related functions. If image encryption support is enabled in MCUboot, then AES algorithms can be shared as well.

Sharing code between the SPE and an external project is possible, even if MCUboot isn't used as the bootloader. For example, a custom bootloader can also be built in such a way as to create the necessary artifacts to share some of its code with the SPE. The same artifacts must be created like the case of MCUboot:

- ***shared_symbols_name.txt*: Contains the name of the shared symbols. Used by** the script that prevents symbol collision.
- *shared_symbols_address.txt*: Contains the type, address and name of shared symbols. Used by the linker when linking runtime SPE.
- *shared_code.axf*: GNUARM specific. The stripped version of the firmware component, only contains the shared code. It is used by the linker when linking the SPE.

Note: The artifacts of the shared code extraction steps must be preserved to be able to link them to any future SPE version.

When an external project is sharing code with the SPE, the *SHARED_CODE_PATH* compile time switch must be set to the path of the artifacts mentioned above.

Further improvements

This design focuses only on sharing the cryptography code. However, other code could be shared as well. Some possibilities:

- Flash driver
- Serial driver
- Image metadata parsing code
- etc.

tf-m@lists.trustedfirmware.org

API Version
0.9

Introduction

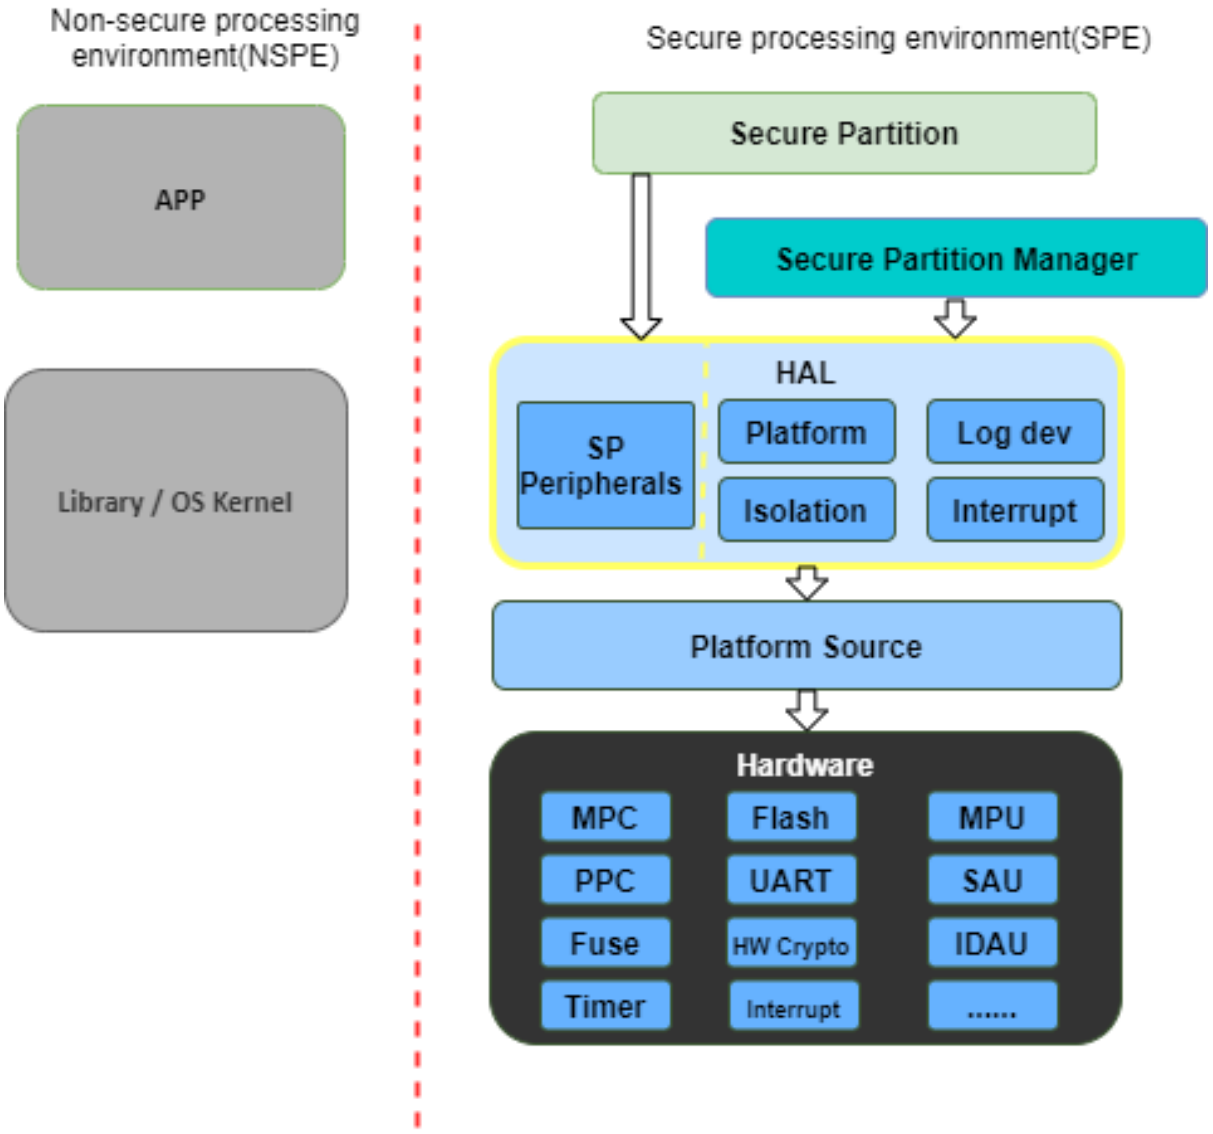
TF-M HAL abstracts the hardware-oriented and platform specific operations on the *SPE* side and provides a set of APIs to the upper layers such as *SPM*, *RoT Service*. The *HAL* aims to cover the platform different aspects whereas common architecturally defined aspects are done generically within the common *SPE*. In some cases, although the operations are defined architecturally, it may not be possible to generalize implementations because lots of information is only known to platforms. It is more efficient to define a *HAL* API for those architectural operations as well.

Note: *TBSA-M* provides the hardware requirements for security purposes. *TF-M HAL* tries to reference *TBSA-M* recommendations in the interfaces from the software perspective only. Please reference *TBSA-M* for your security hardware design.

Design Goals

TF-M HAL is designed to simplify the integration efforts on different platforms.

TF-M HAL is designed to make it easy to use the hardware and develop the *SPM* and *RoT Service* which need to access the devices.



TF-M HAL is designed to make the structure clearer and let the *TF-M* mainly focus on *PSA* implementation.

Overview

This section provides an overview of the abstraction layer structure.

Here lists a minimal set of necessary functionalities:

- **Isolation API**: Provides the necessary isolation functionalities required by the *PSA-FF-M* and *TBSA-M*, and provides APIs to *SPM* to check the permissions of memory access.
- **Platform API**: Provides the platform initialization, platform-specific memory information, system reset, etc.
- **Log dev API**: Provides the log system functions.
- **Interrupt API**: Provides the interrupt functions.

Non-secure processing environment(NSPE)
APP
Library / OS Kernel
Secure processing environment(SPE)
Secure Partition
Secure Partition Manager
HAL
SP Peripherals
Platform
Log dev
Isolation
Interrupt
Platform Source
Hardware
MPC
Flash
MPU
PPC
UART
SAU
Fuse
HW Crypto
IDAU
Timer
Interrupt
.....

Note:

- There is a non-secure *HAL* that focuses on the mailbox operation API for Dual-core topology. For more information about it, please refer to *Mailbox Design in TF-M on Dual-core System*.
- The minimal set of *TF-M HAL* is sufficient for Secure Partitions by using customized peripheral interfaces. To provide easier portability for the Secure Partitions, a Secure Partition *HAL* is provided in this design too.
- The debug mechanisms give the external entity the corresponding right to access the system assets. *TF-M* ensures that the external entity is permitted access to those assets. Currently, *TF-M* only needs the debug authentication. The whole debug mechanism and related *HAL* will be enhanced in the future. Please refer to the *Debug authentication settings section* for more details.

Design Principles

As *TF-M* runs on resource-constrained devices, the *HAL* tries to avoid multiple level abstractions which cost more resources.

Part of the *HAL* interfaces does not focus on exact hardware operations such as power on/off or PIN manipulation. Instead, the *HAL* abstracts higher-level interfaces to reserve the implementation flexibility for the platform vendors.

The *TF-M HAL* should be easy to deprecate APIs and provide compatibilities. Any API incompatibility should be detected during building.

TF-M relies on the *HAL* APIs to be implemented correctly and trusts the *HAL* APIs. *TFM* can provide assertions to detect common programming errors but essentially no further extensive checks will be provided.

Source Files

This section describes the source file of the *TF-M HAL*, including the header and c files.

tfm_hal_defs.h

This header file contains the definitions of common macros and types used by all *HAL* APIs. Please refer to *Status Codes* for detailed definitions.

tfm_hal_[module].[h/c]

All other headers and c files are classified by the modules, such as isolation, platform, interrupt, devices, etc.

Note: There are common files in the platform folder include the implemented *HAL* APIs. The platform vendors can use them directly but need to implement all the sub APIs.

Status Codes

These are common status and error codes for all *HAL* APIs.

Types

tfm_hal_status_t

This is a status code to be used as the return type of *HAL* APIs.

```
enum tfm_hal_status_t {
    TFM_HAL_ERROR_MEM_FAULT = SCHAR_MIN,
    TFM_HAL_ERROR_MAX_VALUE,
    TFM_HAL_ERROR_BAD_STATE,
    TFM_HAL_ERROR_NOT_SUPPORTED,
    TFM_HAL_ERROR_INVALID_INPUT,
    TFM_HAL_ERROR_NOT_INIT,
    TFM_HAL_ERROR_GENERIC,
    TFM_HAL_SUCCESS = 0
};
```

Error Codes

Negative values indicate an error. Zero and positive values indicate success.

Here is the general list. The detailed usages for each error code are described in the API introduction sections.

TFM_HAL_SUCCESS

Status code to indicate general success.

TFM_HAL_ERROR_GENERIC

Status code to indicate an error that does not correspond to any defined failure cause.

TFM_HAL_ERROR_NOT_INIT

Status code to indicate that the module is not initialed.

TFM_HAL_ERROR_INVALID_INPUT

Status code to indicate that the input is invalid.

TFM_HAL_ERROR_NOT_SUPPORTED

Status code to indicate that the requested operation or a parameter is not supported.

TFM_HAL_ERROR_BAD_STATE

Status code to indicate that the requested action cannot be performed in the current state.

TFM_HAL_ERROR_MAX_VALUE

Status code to indicate that the current number has got the max value.

TFM_HAL_ERROR_MEM_FAULT

Status code to indicate that the memory check failed.

API Definition for TF-M SPM

This section describes the APIs defined for *TF-M SPM*.

Platform API

The platform API is a higher-level abstraction layer of the platform, other than a dedicated API set for the special hardware devices.

APIs

tfm_hal_platform_init()

Prototype

```
enum tfm_hal_status_t tfm_hal_platform_init(void)
```

Description

This API performs the platform initializations **before** the *SPM* initialization.

The initializations could include but not limited to: - Fault handlers - Reset configurations - Debug init - NVIC init

Parameter

- void - None.

Return Values

- TFM_HAL_SUCCESS - Init success.
- TFM_HAL_ERROR_GENERIC - Generic errors.

tfm_hal_system_reset()

Prototype

```
void tfm_hal_system_reset(void)
```

Description

This API performs a system reset.

The platform can uninitialize some resources before reset.

When CONFIG_TFM_HALT_ON_CORE_PANIC is disabled this function is called to reset the system when a fatal error occurs.

Parameter

- void - None

Return Values

- void - None

Note

This API should not return.

tfm_hal_system_halt()

Prototype

```
void tfm_hal_system_halt(void)
```

Description

This API enters the CPU into an infinite loop.

The platform can uninitialize some resources before looping forever.

When CONFIG_TFM_HALT_ON_CORE_PANIC is enabled this function is called to halt the system when a fatal error occurs.

Parameter

- void - None

Return Values

- void - None

Note

This API should not return.

Isolation API

The *PSA-FF-M* defines three isolation levels and a memory access rule to provide diverse levels of security. The isolation API provides the functions to implement these requirements.

The Isolation API operates on boundaries. A boundary represents a set of protection settings that isolates components and domains. Below are the boundary examples in the current implementation:

- Boundaries between SPM and Secure Partitions.
- Boundaries between ARoT domain and PRoT domain.

There are two types of boundaries:

- Static boundaries: Set up when the system is initializing and persistent after the initialization. This type of boundary needs the set-up operations only.
- Partition boundaries: Keeps switching from one to another when the system is running. This type of boundary needs both set-up and switching operations.

The boundary operations are abstracted as HAL interfaces because isolation hardwares can be different for platforms:

- The set-up HAL interface creates a partition boundary based on given partition information. This created boundary is bound with the partition for subsequent usage. The binding is done by storing the boundary into partition runtime data.
- The activation HAL interface activates the partition boundary to secure the execution for the partition to be switched. The target partition's information and boundary are given to the activation HAL to accomplish the operation.

The data representing the partition boundary in runtime is defined with the opaque type uintptr_t:

- It is required that one value represents one boundary. The different values represent different boundaries.
- The value is created by HAL implementation with its own-defined encoding scheme.

The HAL implementation defined encoding scheme can be designed for implementation convenience. For example:

- The implementation scheme can encode attribute flags into integer bits. This could help the activation HAL to extract the protection settings quickly from this encoded value, or even write to hardware registers directly in the most ideal case. The initial TF-M Isolation HAL reference implementation applies this scheme.
- The implementation scheme can reference the addresses of isolation hardware description data. This could help the activation HAL to reference the protection settings directly by pointers.

Multiple Secure Partitions can bind with the same boundary value. This flexibility is useful for specific configurations. Take Isolation Level 2 as an example, assigning PRoT and ARoT domain boundaries to respective partitions can make execution more efficient, because switching two partitions in the same domain does not need to change the activated boundary.

The boundary contains the partition's memory accessibility information, hence memory access check shall be performed based on boundary.

Memory Access Attributes

The memory access attributes are encoded as bit fields, you can logic OR them to have a combination of the atrributes, for example TFM_HAL_ACCESS_UNPRIVILEGED | TFM_HAL_ACCESS_READABLE is unprivileged readable. The data type is *uint32_t*.

TFM_HAL_ACCESS_EXECUTABLE

The memory is executable.

```
#define TFM_HAL_ACCESS_EXECUTABLE (1UL << 0)
```

TFM_HAL_ACCESS_READABLE

The memory is readable.

```
#define TFM_HAL_ACCESS_READABLE (1UL << 1)
```

TFM_HAL_ACCESS_WRITABLE

The memory is writable.

```
#define TFM_HAL_ACCESS_WRITABLE (1UL << 2)
```

TFM_HAL_ACCESS_UNPRIVILEGED

The memory is unprivileged mode accessible.

```
#define TFM_HAL_ACCESS_UNPRIVILEGED (1UL << 3)
```

TFM_HAL_ACCESS_DEVICE

The memory is a MMIO device.

```
#define TFM_HAL_ACCESS_DEVICE (1UL << 4)
```

TFM_HAL_ACCESS_NS

The memory is accessible from *NSPE*

```
#define TFM_HAL_ACCESS_NS (1UL << 5)
```

APIs

tfm_hal_verify_static_boundaries()

Prototype

```
fih_int tfm_hal_verify_static_boundaries(void)
```

Description

This API verifies the static isolation boundaries.

Refer to the *PSA-FF-M* for the definitions of the isolation boundaries.

Parameter

- void - None

Return Values

- TFM_HAL_SUCCESS - Verification has been successful.

- TFM_HAL_ERROR_GENERIC - Verification failed.

tfm_hal_set_up_static_boundaries()

Prototype

```
enum tfm_hal_status_t tfm_hal_set_up_static_boundaries(void)
```

Description

This API sets up the static isolation boundaries which are constant throughout the system runtime.

These boundaries include:

- The boundary between the *SPE* and the *NSPE*
- The boundary to protect the SPM execution. For example, the PSA RoT isolation boundary between the PSA Root of Trust and the Application Root of Trust which is for isolation level 2 and 3 only.

Refer to the *PSA-FF-M* for the definitions of the isolation boundaries.

Parameter

- void - None

Return Values

- TFM_HAL_SUCCESS - Isolation boundaries have been set up.
- TFM_HAL_ERROR_GENERIC - Failed to set up the static boundaries.

tfm_hal_bind_boundary()

Prototype

```
enum tfm_hal_status_t tfm_hal_bind_boundary(
                            const struct partition_load_info_t *p_ldinf,
                            uintptr_t *p_boundary);
```

Description

This API binds partition with a platform-generated boundary. The boundary is bound by writing the generated value into p_boundary. And this bound boundary is used in subsequent calls to *tfm_hal_activate_boundary()* when boundary's owner partition get scheduled for running.

Parameter

- p_ldinf - Load information of the partition that is under loading.
- p_boundary - Pointer for holding a partition's boundary.

Return Values

- TFM_HAL_SUCCESS - The boundary has been bound successfully.
- TFM_HAL_ERROR_GENERIC - Failed to bind the handle.

tfm_hal_activate_boundary()

Prototype

```
enum tfm_hal_status_t tfm_hal_activate_boundary(
                          const struct partition_load_info_t *p_ldinf,
                          uintptr_t boundary);
```

Description

This API requires the platform to activate the boundary to ensure the given Secure Partition can run successfully.

The access permissions outside the boundary is platform-dependent.

Parameter

- p_ldinf - The load information of the partition that is going to be run.
- boundary - The boundary for the owner partition of p_ldinf. This value is bound in function tfm_hal_bind_boundary.

Return Values

- TFM_HAL_SUCCESS - the isolation boundary has been set up.
- TFM_HAL_ERROR_GENERIC - failed to set up the isolation boundary.

tfm_hal_memory_check()

Prototype

```
tfm_hal_status_t tfm_hal_memory_check(uintptr_t boundary,
                                      uintptr_t base,
                                      size_t size,
                                      uint32_t access_type)
```

Description

This API checks if a given range of memory can be accessed with specified access types in boundary. The boundary belongs to a partition which contains asset info.

Parameter

- boundary - Boundary of a Secure Partition. Check *tfm_hal_bind_boundary* for details.
- base - The base address of the region.
- size - The size of the region.
- access_type - The memory access types to be checked between given memory and boundaries. The *Memory Access Attributes*.

Return Values

- TFM_HAL_SUCCESS - The memory region has the access permissions.
- TFM_HAL_ERROR_MEM_FAULT - The memory region does not have the access permissions.
- TFM_HAL_ERROR_INVALID_INPUT - Invalid inputs.
- TFM_HAL_ERROR_GENERIC - An error occurred.

Note

If the implementation chooses to encode a pointer as the boundary, a platform-specific pointer validation needs to be considered before referencing the content in this pointer.

tfm_hal_boundary_need_switch()

Prototype

```
bool tfm_hal_boundary_need_switch(uintptr_t boundary_from,
                                  uintptr_t boundary_to)
```

Description

This API let the platform decide if a boundary switch is needed.

Parameter

- boundary_from - Boundary to switch from.
- boundary_to - Boundary to switch to.

Return Values

- true - A switching is needed
- false - No need for a boundary switch

Log API

The log API is used by the *TF-M log system*. The log device could be uart, memory, usb, etc.

APIs

tfm_hal_output_partition_log()

Prototype

```
int32_t tfm_hal_output_partition_log(const unsigned char *str, uint32_t len)
```

Description

This API is called by Secure Partition to output logs.

Parameter

- str - The string to output.
- len - Length of the string in bytes.

Return Values

- Positive values - Number of bytes output.
- TFM_HAL_ERROR_NOT_INIT - The log device has not been initialized.
- TFM_HAL_ERROR_INVALID_INPUT - Invalid inputs when str is NULL or len is zero.

Note

None.

tfm_hal_output_spm_log()

Prototype

```
int32_t tfm_hal_output_spm_log(const unsigned char *str, uint32_t len)
```

Description

This API is called by *SPM* to output logs.

Parameter

- str - The string to output.
- len - Length of the string in bytes.

Return Values

- Positive numbers - Number of bytes output.
- TFM_HAL_ERROR_NOT_INIT - The log device has not been initialized.

- TFM_HAL_ERROR_INVALID_INPUT - Invalid inputs when str is NULL or len is zero.

Note

Please check *TF-M log system* for more information.

Interrupt APIs

The SPM HAL interrupt APIs are intended for operations on Interrupt Controllers of platforms.

APIs for control registers of interrupt sources are not in the scope of this set of APIs. Secure Partitions should define the APIs for managing interrupts with those MMIO registers.

APIs

tfm_hal_irq_enable()

Prototype

```
enum tfm_hal_status_t tfm_hal_irq_enable(uint32_t irq_num)
```

Description

This API enables an interrupt from the Interrupt Controller of the platform.

Parameter

- irq_num - the interrupt to be enabled with a number

Return Values

- TFM_HAL_ERROR_INVALID_INPUT - the irq_num exceeds The maximum supported number of external interrupts.
- TFM_HAL_ERROR_GENERIC - failed to enable the interrupt.
- TFM_HAL_SUCCESS - the interrupt is successfully enabled.

tfm_hal_irq_disable()

Prototype

```
enum tfm_hal_status_t tfm_hal_irq_disable(uint32_t irq_num)
```

Description

This API disables an interrupt from the Interrupt Controller of the platform.

Parameter

- irq_num - the interrupt to be disabled with a number

Return Values

- TFM_HAL_ERROR_INVALID_INPUT - the irq_num exceeds The maximum supported number of external interrupts.
- TFM_HAL_ERROR_GENERIC - failed to disable the interrupt.
- TFM_HAL_SUCCESS - the interrupt is successfully disabled.

tfm_hal_irq_clear_pending()

Prototype

```
enum tfm_hal_status_t tfm_hal_irq_clear_pending(uint32_t irq_num)
```

Description

This API clears an active and pending interrupt.

Parameter

- irq_num - the interrupt to be disabled with a number

Return Values

- TFM_HAL_ERROR_INVALID_INPUT - the irq_num exceeds The maximum supported number of external interrupts.
- TFM_HAL_ERROR_GENERIC - failed to clear the pending interrupt.
- TFM_HAL_SUCCESS - the pending interrupt has been cleared.

Initializations

Prototype

```
enum tfm_hal_status_t {source_symbol}_init(void *p_pt,
                                           const struct irq_load_info_t *p_ildi)
```

The {source_symbol} is:

- irq_{source}, if the source attribute of the IRQ in Partition manifest is a number
- Lowercase of source attribute, if source is a symbolic name

Description

Each interrupt has an initialization function individually. The *SPM* calls the functions while loading the Partitions.

The following initializations are required for each interrupt:

- Setting the priority. The value must between 0 to 0x80 exclusively.
- Ensuring that the interrupt targets the Secure State.
- Saving the input parameters for future use.

Platforms can have extra initializations as well.

Parameter

- p_pt - pointer to Partition runtime struct of the owner Partition
- p_ildi - pointer to irq_load_info_t struct of the interrupt

Note

Please refer to the :doc: *IRQ intergration guide<tfm_secure_irq_integration_guide>* for more information.

API Definition for Secure Partitions

The Secure Partition (SP) *HAL* mainly focuses on two parts:

- Peripheral devices. The peripherals accessed by the *TF-M* default Secure Partitions.
- Secure Partition abstraction support. The Secure Partition data that must be provided by the platform.

The Secure Partition abstraction support will be introduced in the peripheral API definition.

ITS and PS flash API

There are two kinds of flash:

- Internal flash. Accessed by the PSA Internal Trusted Storage (ITS) service.
- External flash. Accessed by the PSA Protected Storage (PS) service.

The ITS HAL for the internal flash device is defined in the tfm_hal_its.h header and the PS HAL in the tfm_hal_ps.h header.

Macros

Internal Trusted Storage

TFM_HAL_ITS_FLASH_DRIVER

Defines the identifier of the CMSIS Flash ARM_DRIVER_FLASH object to use for ITS. It must have been allocated by the platform and will be declared extern in the HAL header.

TFM_HAL_ITS_PROGRAM_UNIT

Defines the size of the ITS flash device's physical program unit (the smallest unit of data that can be individually programmed to flash). It must be equal to TFM_HAL_ITS_FLASH_DRIVER.GetInfo()->program_unit, but made available at compile time so that filesystem structures can be statically sized.

TFM_HAL_ITS_FLASH_AREA_ADDR

Defines the base address of the dedicated flash area for ITS.

TFM_HAL_ITS_FLASH_AREA_SIZE

Defines the size of the dedicated flash area for ITS in bytes.

TFM_HAL_ITS_SECTORS_PER_BLOCK

Defines the number of contiguous physical flash erase sectors that form a logical filesystem erase block.

Protected Storage

TFM_HAL_PS_FLASH_DRIVER

Defines the identifier of the CMSIS Flash ARM_DRIVER_FLASH object to use for PS. It must have been allocated by the platform and will be declared extern in the HAL header.

TFM_HAL_PS_PROGRAM_UNIT

Defines the size of the PS flash device's physical program unit (the smallest unit of data that can be individually programmed to flash). It must be equal to TFM_HAL_PS_FLASH_DRIVER.GetInfo()->program_unit, but made available at compile time so that filesystem structures can be statically sized.

TFM_HAL_PS_FLASH_AREA_ADDR

Defines the base address of the dedicated flash area for PS.

TFM_HAL_PS_FLASH_AREA_SIZE

Defines the size of the dedicated flash area for PS in bytes.

TFM_HAL_PS_SECTORS_PER_BLOCK

Defines the number of contiguous physical flash erase sectors that form a logical filesystem erase block.

Optional definitions

The TFM_HAL_ITS_FLASH_AREA_ADDR, TFM_HAL_ITS_FLASH_AREA_SIZE and TFM_HAL_ITS_SECTORS_PER_BLOCK definitions are optional. If not defined, the platform must implement tfm_hal_its_fs_info() instead.

Equivalently, tfm_hal_its_ps_info() must be implemented by the platform if TFM_HAL_ITS_FLASH_AREA_ADDR, TFM_HAL_ITS_FLASH_AREA_SIZE or TFM_HAL_ITS_SECTORS_PER_BLOCK is not defined.

Objects

ARM_DRIVER_FLASH

The ITS and PS HAL headers each expose a CMSIS Flash Driver instance.

```
extern ARM_DRIVER_FLASH TFM_HAL_ITS_FLASH_DRIVER

extern ARM_DRIVER_FLASH TFM_HAL_PS_FLASH_DRIVER
```

The CMSIS Flash Driver provides the flash primitives ReadData(), ProgramData() and EraseSector() as well as GetInfo() to access flash device properties such as the sector size.

Types

tfm_hal_its_fs_info_t

Struct containing information required from the platform at runtime to configure the ITS filesystem.

```
struct tfm_hal_its_fs_info_t {
    uint32_t flash_area_addr;
    size_t flash_area_size;
    uint8_t sectors_per_block;
};
```

Each attribute is described below:

- flash_area_addr - Location of the block of flash to use for ITS
- flash_area_size - Number of bytes of flash to use for ITS
- sectors_per_block - Number of erase sectors per logical FS block

tfm_hal_ps_fs_info_t

Struct containing information required from the platform at runtime to configure the PS filesystem.

```
struct tfm_hal_ps_fs_info_t {
    uint32_t flash_area_addr;
    size_t flash_area_size;
    uint8_t sectors_per_block;
};
```

Each attribute is described below:

- flash_area_addr - Location of the block of flash to use for PS
- flash_area_size - Number of bytes of flash to use for PS

- sectors_per_block - Number of erase sectors per logical FS block

Functions

tfm_hal_its_fs_info()

Prototype

```
enum tfm_hal_status_t tfm_hal_its_fs_info(struct tfm_hal_its_fs_info_t *fs_info);
```

Description

Retrieves the filesystem configuration parameters for ITS.

Parameter

- fs_info - Filesystem config information

Return values

- TFM_HAL_SUCCESS - The operation completed successfully
- TFM_HAL_ERROR_INVALID_INPUT - Invalid parameter

Note

This function should ensure that the values returned do not result in a security compromise. The block of flash supplied must meet the security requirements of Internal Trusted Storage.

tfm_hal_ps_fs_info()

Prototype

```
enum tfm_hal_status_t tfm_hal_ps_fs_info(struct tfm_hal_ps_fs_info_t *fs_info);
```

Description

Retrieves the filesystem configuration parameters for PS.

Parameter

- fs_info - Filesystem config information

Return values

- TFM_HAL_SUCCESS - The operation completed successfully
- TFM_HAL_ERROR_INVALID_INPUT - Invalid parameter

Note

This function should ensure that the values returned do not result in a security compromise.

Cooperative Scheduling Rules

Author
Ashutosh Singh

Organization
Arm Limited

Contact
Ashutosh Singh <ashutosh.singh@arm.com>

TF-M Scheduler - Rules

On ArmV8-M CPUs, NSPE and SPE share the same physical processing element(PE). A TF-M enabled systems need to be able to handle asynchronous events (interrupts) regardless of current security state of the PE, and that may lead to scheduling decisions. This introduces significant complexity into TF-M. To keep the integrity of (NSPE and SPE) schedulers and call paths between NSPE and SPE, following set of rules are imposed on the TF-M scheduler design.

Objectives and Requirements

1. Decoupling of scheduling decisions between NSPE and SPE
2. Efficient interrupt handling by SPE as well as NSPE
3. Reduce critical sections on the secure side to not block interrupts unnecessarily
4. Scalability to allow simplification/reduction of overheads to scale down the design for constrained devices
5. Reduce impact on NSPE software design

a. NSPE interrupt handling implementation should be independent

b. Impact on the NSPE scheduler should be minimal

c. No assumptions should be made about NSPE's scheduling capabilities

Scheduler Rules for context switching between SPE and NSPE

To allow coherent cooperative scheduling, following set of rules are imposed on security state changes. The switching between SPE and NSPE can be triggered in multiple ways.

Involuntary security state switch; when the software has no control over the switch:

- A NSPE interrupt takes control into NSPE from SPE
- A SPE interrupt takes control into SPE from NSPE

Voluntary security state switch; when software programmatically makes the switch:

- A NSPE exception handler returns from NSPE to pre-empted SPE context
- A SPE exception handler returns from SPE to pre-empted NSPE context
- NSPE makes a function call into SPE
- SPE returns a call from NSPE
- SPE makes a function call into NSPE (not covered in current design)
- NSPE returns a call from SPE (not covered in current design)

In order to maintain the call stack integrity across NSPE and SPE, following rules are imposed on all security state switches.

Rules for NSPE Exception handling

1. **The NSPE exception handler is allowed to trigger a NSPE context switch (regardless of security state of the preempted context.**

This is expected behaviour of any (RT)OS.

2. **The NSPE scheduler must eventually 'restore' the preempted (by exception) context.**

This is expected behaviour of any (RT)OS.

3. **If NSPE exception results in a NSPE context switch, SPM must be informed of the scheduling decision; this must be done BEFORE the execution of newly scheduled-in context.**

This is to ensures integrity of the call stack when SPE is ready to return a previous function call from NSPE.

Rules for SPE Exception handling

1. **All of the SPE interrupts must have higher priority than NSPE interrupts**

This is rule is primarily for simplifying the SPM design.

2. **The SPE interrupt handler is allowed to trigger a SPE context switch (regardless of security state of the pre-empted context)**

If the SPE context targeted by the interrupt is not same as current SPE context, the SPM may choose to switch the current running SPE context based on priority.

3. **SPE scheduler must treat pre-empted context as one of the SPE contexts**

    a. If the pre-empted SPE context is SP1, the TCB for SP1 should be used for saving the context. i.e. the context of SP1 should be saved before scheduling anything other secure partition.

    b. If SP1 was pre-empted by a NSPE interrupt, and subsequent NSPE execution is pre-empted by SPE exception (before NSPE scheduling decision is communicated back to SPM) – SP1 TCB must be used for saving the context In this case SPM is not yet aware of the NSPE context switch, from SPM's standpoint SP1 is still executing, so SPM assumes that the preempted context is SP1.

    c. If SP1 was pre-empted by a NSPE interrupt, and subsequent NSPE execution is pre-empted by SPE exception *after* NSPE scheduling decision is communicated back to SPM) - a TCB dedicated to NSPE should be used for saving the context.

    When NSPE scheduler communicates the scheduling decision to SPM, SPM must save the SP1 context, if a SPE interrupt preempts the currently running NSPE context, SPM should save the context to a dedicated NSPE TCB.

    d. The SPE scheduler must eventually 'restore' the pre-empted context. This is an expected behaviour of any scheduler.

4. **All of the interrupts belonging to a partition must have same priority.**

This serializes ISR execution targeted for same partition.

5. **In case of nested interrupts, all of the ISRs must run to finish before any service code is allowed to run**

This is an expected behaviour of any scheduler.

6. **If the previously preempted context was a NSPE ISR context, SPE ISR handler must return to preempted NSPE context.**

This is an expected behaviour of any scheduler to return to preempted context.

Rules for NSPE to SPM function call (and NSPE scheduler)

1. Current NSPE context must have been communicated to SPM, otherwise SPM cannot guarantee NSPE function calling stack integrity.

Rules for Function Return from SPE to NSPE with result

1. **The result available on SPE side are for currently active NSPE context.**

To maintain call stack integrity, if SPE is ready to return to NSPE, it can do function return only if the SPE return path corresponds to currently active NSPE context.

2. **Last entry into secure world happened programmatically (Voluntary security state switch into SPE)**

i.e. control is voluntarily given back by NSPE, either through a function call, or a context restore via 'return to SPE from NSPE'. As opposed to a SPE interrupt bringing back the execution into SPE.

3. **The current NSPE call stack has not already been returned with SPM_IDLE.**

This rule applies if following optional feature is enabled.

Rules for Return from SPE to NSPE with SPM_IDLE

This is optional part of the design as it introduces significant complexity on both sides of the security boundary. It allows yielding of the CPU to NSPE when SPE has not CPU execution to do but it has not yet finished the previous request(s) from NSPE; i.e. SPE is waiting on arrival of a SPE interrupt.

1. **Last entry into secure world happens programmatically (Voluntary security context switch into SPE)**

i.e. control is voluntarily given back by NSPE, either through a function call, or a context restore via 'return to SPE from NSPE'. As opposed to a SPE interrupt bringing back the execution into SPE.

2. **The result for the currently active NSPE entity is not yet available, the called service is waiting (on interrupt/event).**

SPE request corresponding to currently active NSPE caller is not yet completed and is waiting on an ISR.

3. **The current NSPE call stack has not already been returned with SPM_IDLE.**

Rules for NSPE pend irq based return from SPE to NSPE

This is optional part of the design as it introduces significant complexity on both sides. This works in conjunction with [Rules for Return from SPE to NSPE with SPM_IDLE](#rules-for-return-from-spe-to-nspe-with-spm_idle). In this scenario, when SPE is ready with result for a previous call from NSPE, it raises a pended IRQ to NSPE instead of returning the function call path.

1. **The SPE has finished a NSPE request.**
2. **The corresponding NSPE context has already been returned with SPM_IDLE.**

Rules for ISR pre-emption

1. **A higher priority NSPE interrupt is allowed to preempt a lower priority NSPE ISR**
2. **A higher priority SPE interrupt is allowed to preempt a lower priority SPE ISR**
3. **A SPE interrupt is allowed to preempt NSPE ISR**
4. **A NSPE interrupt is not allowed to preempt SPE ISR**
5. **All interrupts belonging to a service must have same priority**

Code Generation With Jinja2

Author
Mate Toth-Pal

Organization
Arm Limited

Mate Toth-Pal <mate.toth-pal@arm.com>

Generating files from templates in TF-M

Some of the files in TF-M are generated from template files. The files to be generated are listed in tools/tfm_generated_file_list.yaml. For each generated file <path_to_file>/<filename> the template file is <path_to_file>/<filename>.template. The templates are populated with partition information from the partition manifests. The manifests to be used for the generation are listed in tools/tfm_manifest_list.yaml.

Custom generator script - Current method

tools/tfm_parse_manifest_list.py Python script is used to generate files from the templates. This script calls the tools/generate_from_template.py to parse the template files, and uses tools/keyword_substitution.py to substitute the keychains with actual values from the manifest files.

Use Jinja2 template engine - proposal

The proposal is to eliminate the template parser and substituter scripts, and call the Jinja2 template engine library from tools/tfm_parse_manifest_list.py to do the substitution.

More information on jinja2: http://jinja.pocoo.org/

Changes needed:

- tools/tfm_parse_manifest_list.py have to be modified to call the Jinja2 library instead of the custom scripts. The data structure required by the library is very similar to the one required by the current scripts.
- template files needs to be rewritten to the Jinja syntax: The control characters to be replaced (like @! -> {%) and for statements to be added to iterate over the substitutions.

Improvements over the current solution

- Compatible with Python 2.7 and Python 3, while current solution only supports Python 2.7
- More advanced functionality: direct control over the list of items for a keychain, meta information on that list (like length)
- Well documented (see website)
- Jinja2 is free and open-source software, BSD licensed, just like TF-M. It is a well established software in contrast with the current proprietary solution.

Example

Below code snippet enumerates services in Secure Partitions:

```
{% for partition in partitions %}
   {% if partition.manifest.services %}
      {% for service in partition.manifest.services %}
         {do something for the service}
      {% endfor %}
   {% endif %}
{% endfor %}
```

Fixing implicit casting for C enumeration values

Author
Hugues de Valon

Organization
Arm Limited

Contact
hugues.devalon@arm.com

Abstract

C enumerations provide a nice way to increase readability by creating new enumerated types but the developer should take extra care when mixing enumeration and integer values. This document investigates C enumerations safety and proposes strategies on how to fix the implicit casting of the enumeration values of TF-M with other types.

C99 Standard point of view

In TF-M many implicit casts are done between integer types (uint32_t, int32_t, size_t, etc), enumerated types (enum foobar) and enumeration constants (FOOBAR_ENUM_1).

According to the C99 standard[1]:

> **§6.2.5, 16**: An enumeration comprises a set of named integer constant values. Each distinct enumeration constitutes a different numerated type.
>
> **§6.7.2.2, 2**: The expression that defines the value of an enumeration constant shall be an integer constant expression that has a value representable as an int.
>
> **§6.7.2.2, 3**: The identifiers in an enumerator list are declared as constants that have type int and may appear wherever such are permitted.
>
> **§6.7.2.2, 4**: Each enumerated type shall be compatible with char, a signed integer type, or an unsigned integer type. The choice of type is implementation-defined, but shall be capable of representing the values of all the members of the enumeration.

From these four quotes from the C99 standard[Page 1221, 1], the following conclusions can be made:

- an enumeration defines a new type and should be treated as such
- the enumeration constants must only contains value representable as an int
- the enumeration constants have type int
- the actual type of the enumeration can be between char, signed and unsigned int. The compiler chooses the type it wants among those that can represent all declared constants of the enumeration.

Example:

```
enum french_cities {
    MARSEILLE,
    PARIS,
    LILLE,
    LYON
};
```

In that example, MARSEILLE, PARIS, LILLE and LYON are enumeration constants of type int and enum french_cities is a enumerated type which can be of actual type char, unsigned int or int (the compiler chooses!).

For these reasons, doing an implicit cast between an enumeration and another type is the same as doing an implicit cast between two different types. From a defensive programming point of view, it should be checked that the destination type can represent the values from the origin type. In this specific case it means four things for enumerations:

- it is always safe to assign an enumeration constant to an int, but might be better to cast to show intent.

[1] C99 standard: http://www.open-std.org/jtc1/sc22/WG14/www/docs/n1256.pdf

- when casting an enumeration constant to another type, it should be checked that the constant can fit into the destination type.
- when casting from an integer type (uint32_t, int32_t, etc) to an enumeration type, it should be checked that the integer's value is one of the enumeration constants. The comparison needs to be done on the biggest type of the two so that no information is lost. C integer promotion should automatically do that for the programmer (check §6.3.1.8, 1 for the rules).
- when casting from an enumeration type to an integer type, it should be checked that the enumeration type value fits into the integer type. The value of a variable which has the type of an enumeration type is not limited to the enumeration constants of the type. An enumeration constant will always fit into an int.

Strategies to fix

0. Replace the enumerated type with an integer type and replace the enumeration constant with preprocessor constants.
1. Whenever possible, try to use matching types to avoid implicit casting. It happens, for example, for arithmetic operations, function calls and function returns. This strategy always have the lowest performance impact.
2. When using an enumeration constant in an arithmetic operation with another type, verify that the constant can fit in the other type and cast it.
3. When converting an integer to an enumeration type, use a conversion function to check if the integer matches an enumeration constant. To not impact performance too much, this function should be an inline function. If it does not match, use (or add) the error constant or return an error value.
4. When converting an enumeration type to an integer, use a conversion function to check that the integer type can contain the enumeration value.

Design proposal for TF-M

In TF-M, an action will be taken for all enumerated types and enumeration constants that are used for implicit casting. The goal of this proposal is to remove all implicit casting of enumeration values in TF-M.

The following enumerated types will be removed and replaced with preprocessor constants (strategy 0). These enumerated types are not used in TF-M but only the constants they declare.

- enum spm_part_state_t
- enum spm_part_flag_mask_t
- enum tfm_partition_priority

The following enumerated types will be kept because they are used in the prototypes of functions and are useful for debugging. Whenever possible, strategy 1 will be applied to remove implicit casting related with those enumerations but dynamic conversions will be used if the first option would create too much change in the code base.

- enum tfm_status_e: the return type of the following functions will be changed to return the enum tfm_status_e type. These functions are already returning the enumeration constants, but implicitly casted to an integer type like int32_t.
  - int32_t check_address_range
  - int32_t has_access_to_region
  - int32_t tfm_core_check_sfn_parameters
  - int32_t tfm_start_partition
  - int32_t tfm_return_from_partition

  - int32_t tfm_check_sfn_req_integrity
  - int32_t tfm_core_check_sfn_req_rules
  - int32_t tfm_spm_sfn_request_handler
  - int32_t tfm_spm_sfn_request_thread_mode
- enum tfm_buffer_share_region_e: the following function prototypes will be changed:
  - tfm_spm_partition_set_share(uint32_t partition_idx, uint32_t share) -> tfm_spm_partition_set_share(uint32_t partition_idx, enum tfm_buffer_share_region_e share)
- enum tfm_memory_access_e
- enum attest_memory_access_t
- enum engine_cipher_mode_t
- mbedtls_cipher_type_t

The following enumerated types are used for error code values of Secure service calls. They should be kept as they are part of the interface and might be used by external parties in Non-Secure code. For the Initial Attestation service, the enumeration is defined in the PSA Attestation API specifications.

- enum psa_attest_err_t
- enum psa_audit_err
- enum tfm_platform_err_t

Implicit casting related with these enumerations is happening in two locations of TF-M and need conversion functions in those locations, because the types can not be changed:

- In the Non-Secure Client library, all of the Secure Service functions implicitly cast the uint32_t returned by tfm_ns_lock_dispatch to these enumerated types. Strategy 3 is needed here.
- In all of the veneer functions, there is an implicit cast from the int32_t value returned by the SVC request function (tfm_core_*_request) to these enumerated types. Strategy 3 is needed here as well. The implicit cast will eventually be removed if all of the services are using the Uniform Signatures Prototypes so that the veneer functions all return psa_status_t which is an int32_t.

If the interface of those services can be changed, these enumerations could be removed and replaced with the psa_status_t type to remove the implicit casting.

FF-M Isolation

Organization
Arm Limited

Contact
tf-m@lists.trustedfirmware.org

This document analyzes the isolation rules of implementing FF-M 1.0 isolation and introduces the reference implementation in TF-M, which complies the rules by operating the hardware and software resources.

Note: Reference the document *Glossary* for terms and abbreviations.

Introduction

This chapter describes the definitions from FF-M and analyzes the possible implementation key-points.

Isolation Levels

There are 3 isolation levels (1-3) defined in FF-M, the greater level number has more isolation boundaries.

The definition for Isolation Level 1:

- L1.1 NPSE needs protection from nobody.
- L1.2 SPE needs protection from NSPE.

The definition for Isolation Level 2:

- L2.1 NPSE needs protection from nobody.
- L2.2 Application Root of Trust (ARoT) needs protection from NSPE.
- L2.3 PSA Root of Trust (PRoT) needs protection from NSPE and ARoT.

The definition for Isolation Level 3:

- L3.1 NPSE needs protection from nobody.
- L3.2 Secure Partition needs protection from NSPE and other Secure Partitions.
- L3.3 PSA Root of Trust (RoT) domain needs protection from NSPE and all Secure Partitions.

Important: A Secure Partition RoT Service is a Root of Trust Service implemented within a Secure Partition. An Application RoT Service must be implemented as a Secure Partition RoT Service. But it is implementation-defined whether a PSA RoT Service is a Secure Partition RoT Service.

Here listed several possible PSA RoT Service implementation mechanisms:

1. Implement PSA RoT Services in Secure Partitions with respective boundaries.
2. Implement PSA RoT Services in Secure Partitions, but no boundaries between these Secure Partitions as they are in the PSA RoT Domain.
3. Implement PSA RoT Services in a customized way instead of Secure Partitions, an internal library of PSA RoT domain e.g.

TF-M chooses the 2nd option to balance performance and complexity.

Isolation Rules

The essence of isolation is to protect the assets of one protection domain from being accessed from other domains. The isolation levels define where the isolation boundaries should be placed, the isolation rules define the strength of the isolation the boundaries should offer.

Note: Refer to chapter *Memory Assets* in Firmware Framework for M (FF-M) to know asset class items. Assets are represented by memory addresses in the system memory map, which makes assets named *Memory Assets*. The often-seen asset items are ROM, RAM, and memory-mapped peripherals.

Memory Asset Class

There are 3 memory asset classes defined in Firmware Framework for M (FF-M):

- Code
- Constant data
- Private data

There are 6 isolation rules for protecting assets. Here lists the simplified description for the rules, check chapter 3.1.2 of FF-M 1.0 for the original description:

- I1. Only Code is executable.
- I2. Only private data is writable.
- I3. If domain A needs protection from domain B, then Private data in domain A cannot be accessed by domain B.
- I4. (Optional) If domain A needs protection from domain B, then Code and Constant data in domain A is not readable or executable by domain B.
- I5. (Optional) Code in a domain is not executable by any other domain.
- I6. (Optional) All assets in a domain are private to that domain and cannot be accessed by any other domain, with the following exception: The domain containing the SPM can only access Private data and Constant data assets of other domains when required to implement the PSA Firmware Framework API.
- I7. (Optional, added in FF-M 1.1) Constant data is not executable.

  The first 3 rules from I1 to I3 defines the mandatory rules to comply the isolation, while I4 to I6 are optional rules to enhance the isolation boundaries.

Important: There is a table in the chapter 3.1.2 of FF-M 1.0 under I1 lists the asset types and allowed access method. Preventing executable access on constant data costs more hardware resources, so there is an optional rule I7 created in FF-M Extensions (FF-M 1.1) to comfort implementations with constrained hardware resources.

Hardware Infrastructure

To implement a secure system, the hardware security framework (TrustZone or multiple-core e.g.) and their auxiliary components (SAU e.g.) are required to ensure the isolation between SPE and NSPE. The requirements:

Important: The interface between secure and non-secure states needs to be fully enumerated and audited to prove the integrity of the secure state isolation.

Besides this SPE and NSPE isolation mechanism, the following analyzes the implementation rules to find out the hardware requirements for isolation inside SPE domains:

- I1 and I2: The assets can be categorized into 3 *Memory Asset Class*, each type has the specific access rules.
- I3: The private data access from the prevented domain needs to be blocked.
- I4: All the assets access from the prevented domain needs to be blocked.
- I5: Code execution from all other domains (even the domain not prevented from) needs to be blocked.
- I6: All the assets access from all other domains (includes non-prevented domain) needs to be blocked, but, SPM is an exception, which can access the private data and constant data of the current domain.

The above items list the requirements for memory access, here are two more points:

- If the memory device or the peripheral are shared between multiple hosts (Such as multiple CPU or DMA, etc), specific hardware protection units need to be available for validating accesses to that device or peripheral.
- The MMIO range for Secure Partitions is not allowed to be overlapped, which means each partition should have exclusive memory-mapped region if they require a peripheral device. The memory-mapped region is regarded as the private data so access to this area needs to be validated.

Reference Implementation

This chapter describes the isolation implementation inside SPE by using the Armv8m architecture component - Memory Protection Unit (MPU). The MPU can isolate CPU execution and data access.

Note: Previous version M-profile architecture MPU setting is similar in concept but the difference in practical register formats, which is not described in this document.

The MPU protects memory assets by regions. Each region represents a memory range with specific access attributes.

Note: The maximum numbers of MPU regions are platform-specific.

The SPM is running under the privileged mode for handling access from services. The MPU region for SPM needs to be available all the time since SPM controls the MPU setting while scheduling.

Since partitions are scheduled by SPM, the MPU regions corresponding to the partitions can be configured dynamically while scheduling. Since there is only one running at a time and all others are deactivated, the SPM needs to set up necessary regions for each asset type in one partition only.

There is re-usable code like the C-Runtime and RoT Service API which are same across different partitions. TF-M creates a Secure Partition Runtime Library (SPRTL) as a specific library shared by the Secure Partition. Please refer to *Secure Partition Runtime Library* for more detail.

Note: Enable SPRTL makes it hard to comply with the rules I4, I5 and I6, duplicating the library code can be one solution but it is not “shared” library anymore.

As mentioned in the last chapter, MMIO needs extra MPU regions as private data.

MPU Region Access Permission

The following content would mention the memory access permission to represent the corresponded asset classes.

These access permissions are available on Armv8m MPU:

- Privileged Read-Only (RO)
- All RO
- Privileged Read-Write (RW)
- All RW
- Execution Never (XN)

And one more Armv8.1M access permssion:

- Privileged Execution Never (PXN)

The available regions type list:

Type	Attributes	Privilege Level	Asset
P_RO	RO	Privileged	PRoT Code
P_ROXN	RO + XN	Privileged	PRoT Constant Data
P_RWXN	RW + XN	Privileged	PRoT Private Data/Peripheral
A_RO	RO	Any privilege	Partition/SPRTL Code
A_ROXN	RO + XN	Any privilege	Partition/SPRTL Constant Data
A_RWXN	RW + XN	Any privilege	Partition/SPRTL Private Data/Peripheral
A_ROPXN	RO + PXN	Any privilege	Armv8.1M Partition/SPRTL Code

Example Image Layout

The secure firmware image contains components such as partitions, SPM and the shared code and data. Each component may have different class assets. There would be advantages if placing the assets from all components with the same access attributes into one same region:

- The data relocating or clearing when booting can be done in one step instead of breaking into fragments.
- Assets with statically assigned access attribute can share the same MPU region which saves regions.

Take the TF-M existing implementation image layout as an example:

```
 Level 1      Level 2             Level 3
 Boundaries   Boundaries          Boundaries
+-----------+---------+-----------------------------------+
|           |         |   PRoT SPM                 Code   |
|           | PRoT    +-----------------------------------+
|           | Code    |   PRoT Service             Code   |
|  Code     +---------+-----------------------------------+
|  (ROM)    |         |   Partition 1              Code   |
|           |         +-----------------------------------+
|           | ARoT    |   Partition N              Code   |
|           | Code    +-----------------------------------+
|           |         |   SPRTL                    Code   |
+-----------+---------+-----------------------------------+
Check [4] for more details between Code and Constant Data.
+-----------+---------+-----------------------------------+
|           | PRoT    |   PRoT SPM       Constant Data    |
|           | Constant+-----------------------------------+
|           | Data    |   PRoT Service   Constant Data    |
|  Constant +---------+-----------------------------------+
|   Data    | ARoT    |   Partition 1    Constant Data    |
|   (ROM)   | Constant+-----------------------------------+
|           | Data    |   Partition N    Constant Data    |
|           |         +-----------------------------------+
|           |         |   SPRTL          Constant Data    |
+-----------+---------+-----------------------------------+

+-----------+---------+-----------------------------------+
|           | PRoT    |   PRoT SPM       Private Data     |
|           | Private +-----------------------------------+
|           | Data    |   PRoT Service   Private Data     |
|  Private  +---------+-----------------------------------+
|   Data    |         |   Partition 1    Private Data     |
|   (RAM)   | ARoT    +-----------------------------------+
|           | Private |   Partition N    Private Data     |
```

(continues on next page)

(continued from previous page)

```
|           | Data     +----------------------------------+
|           |          |  SPRTL          Private Data     |
+-----------+----------+----------------------------------+
```

Note:

1. Multiple binaries image implementation could also reference this layout if its hardware protection unit can cover the exact boundaries mentioned above.
2. Private data includes both initialized and non-initialized (ZI) sections. Check chapter 3.1.1 of FF-M for the details.
3. This diagram shows the boundaries but not orders. The order of regions inside one upper region can be adjusted freely.
4. As described in the important of *Memory Asset Class*, the setting between Code and Constant Data can be skipped if the executable access method is not applied to constant data. In this case, the groups of Code and Constant Data can be combined or even mixed – but the boundary between PRoT and ARoT are still required under level higher than 1.

Example Region Numbers under Isolation Level 3

The following table lists the required regions while complying the rules for implementing isolation level 3. The level 1 and level 2 can be exported by simplifying the items in level 3 table.

Important: The table described below is trying to be shared between all supported platforms in Trusted Firmware - M. It is obvious that some platforms have special characteristics. In that case, the specific layout table for a particular platform can be totally redesigned but need to fulfil the isolation level requirements.

- Care only the running partitions assets since deactivated partition does not need regions.
- *X* indicates the existence of this region can't comply with the rule.
- An *ATTR* + *n* represent extra n regions are necessary.
- Here assumes the rules with a greater number covers the requirements in the rules with less number.

Here lists the required regions while complying with the rules:

Region Purpose	I1 I2 I3	I4	I5	I6
PRoT SPM Code	A_RO	P_RO	P_RO	P_RO
PRoT Service Code				A_ROPXN
Active Partition Code		A_RO	A_ROPXN	
SPRTL Code		X	X	X
PRoT SPM RO	A_ROXN	P_ROXN	P_ROXN	P_ROXN
PRoT Service RO				A_ROXN
Active Partition RO		A_ROXN	A_ROXN	
SPRTL RO		X	X	X
PRoT SPM RW	P_RWXN	P_RWXN	P_RWXN	P_RWXN
PRoT Service RW				A_RWXN
Active Partition RW	A_RWXN	A_RWXN	A_RWXN	
SPRTL RW [5]	A_RWXN + 1	X	X	X
Partition Peri	A_RWXN + n	A_RWXN + n	A_RWXN + n	A_RWXN + n
Total Numbers	[1]	[2]	[3]	[4]

Note:

1. Total number = A_RO + A_ROXN + P_RWXN + A_RWXN + (1 + n)A_RWXN, while n equals the maximum peripheral numbers needed by one partition. This is the configuration chosen by the reference implementation.
2. Total number = P_RO + P_ROXN + P_RWXN + A_RO + A_ROXN + (1 + n)A_RWXN, the minimal result is *6*, and SPRTL can not be applied.
3. Total number = P_RO + P_ROXN + P_RWXN + A_ROXN + (1 + n)A_RWXN + A_ROPXN, the minimal result is *6*, SPRTL can not be applied, and PXN is required.
4. Total number = P_RO + P_ROXN + P_RWXN + A_ROXN + (1 + n)A_RWXN + A_ROPXN, the minimal result is *6*, SPRTL can not be applied, and PXN is required. To comply with this rule, the PSA RoT Service needs to be implemented as Secure Partitions.
5. This data belongs to SPRTL RW but it is set as Read-Only and only SPM can update this region with the activate partition's metadata for implementing functions with owner SP's context, such as heap functions. This region can be skipped if there is no metadata required (such as no heap functionalities required).

The memory-mapped regions for peripherals have different memory access attributes in general, they are standalone regions in MPU even their attributes covers 'A_RWXN'.

Default access rules

Hardware protection components MAY have the capability to collect regions not explicitly configured in static or runtime settings, and then apply default access rules to the collected. Furthermore, one default rule can be applied to multiple non-contiguous regions which makes them share a common boundary. This operation sets up a standalone 'region' as same as other explicitly configured regions. And it doesn't affect the analysis summary above - just be aware that some regions listed in the table MAY not be explicitly configured.

Take the MPU as an example, MPU can assign a default privileged access attribute to the regions (SPM and PRoT regions e.g.) not explicitly configured. This feature can reduce required MPU regions and ease the programming because regions can be put non-address-contiguous and skip the explicit configuration.

Important: When this default access rules mechanism is applied, the non-explicitly-expressed regions must be reviewed to ensure the isolation boundaries are set properly.

Interfaces

The isolation implementation is based on the HAL framework. The SPM relies on the HAL API to perform the necessary isolation related operations.

The requirement the software need to do are these:

- Create enough isolation protection at the early stage of system booting, just need to focus on the SPM domain.
- Create an isolation domain between secure and non-secure before the jump to the non-secure world.
- Create an isolation domain for each Secure Partition after the Secure Partition is loaded and before jumping to its entry point. The isolation domain should cover all the assets of the Secure Partition, include all its memory, interrupts, and peripherals.
- Switch isolation domains when scheduling different Secure Partitions.

- It is also a requirement that the platform needs to help to check if the caller of the PSA APIs is permitted to access some memory ranges.

The design document *TF-M Hardware Abstraction Layer* gives a detail design, include the platform initialization, isolation interfaces. Please refer to it for more detail.

TF-M builtin keys

Author
Raef Coles

Organization
Arm Limited

Contact
raef.coles@arm.com

Introduction

When TF-M is integrated on a platform, the platform itself can provide several keys for usage which are bound to the device instead of being owned by a specific secure partition. When those keys are readable by the secure processing environment, the platform must provide a function to load these keys in the HAL layer, either loading them from OTP or another platform specific location or subsystem. These keys are henceforth referred to as "builtin keys", and might include (but are not limited to) the following:

1. The Hardware Unique Key (HUK)
2. The Initial Attestation Key (IAK)

The tfm_builtin_key_loader component implements a mechanism to discover those keys and make them available to the PSA Crypto APIs for usage. Note that if a key is stored in a subsystem which can't be read by the secure processing environment, a full opaque driver[1] must be used to be able to use those keys through the PSA Crypto APIs. This document focuses only on the case where the keys can be read by the SPE (i.e. running TF-M), so the driver applies only on those cases, which can be considered as "_transparent_ builin keys".

In TF-M's legacy solution, the IAK is loaded by the attestation service as a volatile key, which requires some key-loading logic to be implemented by that partition. The HUK is not loaded in the crypto service, and is instead used by an implementation of a TF-M specific KDF algorithm which then loads the key and invokes Mbed TLS directly. Both solutions are far from ideal as they require an effort to load (and duplicate) the keys per each user, or require a dedicated code in TF-M that directly interacts with the HAL layer and invokes functions from the crypto library

[1] PSA cryptoprocessor driver interface: https://github.com/Mbed-TLS/mbedtls/blob/development/docs/proposed/psa-driver-interface.md

bypassing the PSA Crypto interface. The aim of the tfm_builtin_key_loader driver is to provide a uniform interface to use the builtin keys available in a platform.

Implementing a driver to deal with builtin keys allows to expand the legacy solution for dealing with this type of keys in several ways. For example, it avoids the need for partitions to implement dedicated mechanisms for probing the HAL layer for builtin keys and load them as volatile. It removes the need to have implementation specific call flows for deriving keys from the HUK (as that requirement now is fulfilled by the driver itself transparently). It allows uniform access to the keys also from the NS world (in any case, subject to the policy dictated by the platform). Correctly abstracts away details of the key handling mechanism from TF-M partitions into the PSA Crypto core key management subsystem.

PSA builtin keys

The PSA Cryptographic API provides a mechanism for accessing keys that are stored in platform-specific locations (often hardware accelerators or OTP). A builtin key is assigned a specific key_id, i.e. a handle, which is hardcoded at build time and must be selected in the range [MBEDTLS_PSA_KEY_ID_BUILTIN_MIN, MBEDLTS_PSA_KEY_ID_BUILTIN_MAX]. A user of the PSA Crypto API can reference those keys directly by using these handles. It is up to the platform to specify policy restrictions for specific users of the keys, e.g. an NS entity, or a secure partition. The PSA Crypto core will then check those policies to grant or deny access to the builtin key for that user.

PSA cryptoprocessor driver API

The PSA specification allows the PSA Crypto APIs to defer their operation to an accelerator driver, through a mechanism described in the PSA cryptoprocessor driver interface specification[Page 1230, 1]. This specification defines the concept of PSA Crypto core, i.e. “An implementation of the PSA Cryptography API is composed of a core and zero or more drivers”. The PSA specification also has the concept of storage locations for keys, through the type psa_key_location_t, which is used to access keys that don’t have local storage[2]. This is leveraged mainly by opaque drivers mainly that use keys for which the key material is not readable by the PSA crypto core layer.

TF-M defines a software driver called tfm_builtin_key_loader that provides no acceleration but just defines a dedicated key location defined through the TFM_BUILTIN_KEY_LOADER_KEY_LOCATION define. By resorting to the entry points provided by this driver, the PSA Crypto core slot management subsystem can access keys stored in the underlying platform, validate key usage policies and allow PSA Crypto APIs to uniformly access builtin keys using the same call flows used with traditional local-storage keys.

This is implemented by hooking the entry points defined by the driver into the library/psa_crypto_driver_wrappers.c file provided by the PSA Crypto core. This is currently done manually but eventually could be just autogenerated by parsing a description of the driver entry points in the JSON format. These entry points are:

1. tfm_builtin_key_loader_init
2. tfm_builtin_key_loader_get_key_buffer_size
3. tfm_builtin_key_loader_get_builtin_key

The call flow for the entry points from the driver wrapper layer is as follows:

1. During the driver initialisation phase started by the PSA Crypto Core init, the tfm_builtin_key_loader_init function is called to probe the platform HAL and retrieve the builtin keys. Those keys are described by the types defined in the HAL layer interface header tfm_plat_crypto_keys.h. In particular global tables describing key properties and user policies must be implemented by each platform and are retrieved by the two accessor functions tfm_plat_builtin_key_get_desc_table_ptr() and

[2] Definition of psa_key_location_t type in the PSA spec: https://arm-software.github.io/psa-api/crypto/1.1/api/keys/lifetimes.html#c.psa_key_location_t

tfm_plat_builtin_key_get_policy_table_ptr(). The keys are loaded from the platform in secure RAM in the TF-M Crypto partition with associated metadata. It's worth to note that the keys are loaded through callback functions which the platform lists in the key descriptor table.

2. Once the TF-M Crypto service is initialised, at runtime it might receive a request through an API call to use one of the builtin key IDs. Those IDs are described in the tfm_builtin_key_ids.h header. Platforms can override the default values providing their own header.
3. When the PSA Crypto core in the psa_get_and_lock_key_slot() function checks that the key_id being requested is in the builtin range region, it probes the platform through the function mbedtls_psa_platform_get_builtin_key which must be implemented by the TF-M Crypto service library abstraction layer. This function just checks the key descriptor table from the HAL to understand if such key_id is available in the platform and what are the corresponding slot and lifetime values associated to it. The lifetime contains the location of the key, which determines which driver is responsible for dealing with it (for the tfm_builtin_key_loader driver, that is TFM_BUILTIN_KEY_LOADER_KEY_LOCATION), while the slot value maps the key to the slot in the driver internal storage.
4. At this point, the PSA Crypto core knows that the key exists and is bound to the location associated to the driver. By calling into the driver wrappers layer is then able to retrieve the key attributes stored in the platform for that key ID, and the size required to allocate in its internal slot management system in order to load the key material in the core. This is done by calling tfm_builtin_key_loader_get_builtin_key just with a valid key attributes pointer (and nothing else), to retrieve the attributes. Once the attributes are available, the required size is retrieved through the driver wrapper by calling tfm_builtin_key_loader_get_key_buffer_size.
5. At this stage, the slot management subsystem calls again into the driver wrapper layer through tfm_builtin_key_loader_get_builtin_key with a valid buffer to hold the key material returned by the tfm_builtin_key_loader driver. When loading the key, the user requiring that key_id is validated by the driver code against the policies defined by the platform. If the policies match, the builtin key material and metadata is loaded and is used like a transparent key available to the PSA Crypto core slot management subsystem.

Technical details

Builtin key IDs and overriding

TF-M builtin key IDs are defined in interface/include/crypto_keys/tfm_builtin_key_ids.h through the enum tfm_key_id_builtin_t. They are allocated inside the range that PSA specifies for the builtin keys, i.e. between MBEDTLS_PSA_KEY_ID_BUILTIN_MIN and MBEDLTS_PSA_KEY_ID_BUILTIN_MAX. A platform can specify extra builtin key IDs by setting the PLATFORM_DEFAULT_CRYPTO_KEYS variable to OFF, creating the header tfm_builtin_key_ids.h, and specifying new keys and IDs.

Builtin key access control

A builtin key is accessible by all callers since the key_id associated to it is public information. Access to the keys must be mediated, which is done by matching the user requesting the key_id against the policies available for that user on that particular key in the policy table. If no policies are specified for a specific combination of user and key_id, the usage flags in the key attributes will be all set to zeros, meaning the key will be unusable for any operation for that particular user.

Multi-partition key derivation

The HUK is used for key derivation by any secure partition or NS caller that requires keys that are bound to a particular context. For example, Protected Storage derives keys uniquely for each user of the service which are used to encrypt user files. In order to provide HUK derivation to

every secure partition / NS caller, it must be ensured that no service that utilises HUK derivation can derive the same key as another service (simply by using the same inputs for the KDF APIs, i.e. accessing the same base key for derivation).

This is accomplished by deriving a further "platform key" for each builtin key that has PSA_KEY_USAGE_DERIVE set in its attributes. These platform keys are derived from the builtin key, using the partition ID as a KDF input, and can then be used for safely for further derivations by the user, without risks to derive the same keys as other users. This is enforced directly by the tfm_builtin_key_loader driver.

Note: If the NS client ID feature is disabled, all NS callers share a partition ID of -1, and therefore will share a platform key and be therefore be able to derive the same keys as other NS callers.

For keys that are not exposed outside the device, this is transparent to the service that is using the key derivation, as they have no access to the builtin key material and cannot distinguish between keys derived directly from it and keys derived from the platform key. For some builtin keys, deriving platform keys is not acceptable, as the key is used outside the device (i.e. the IAK public key is used to verify attestation tokens) so the actual builtin key is used.

The decision has been taken to derive platform keys for any key that can be used for key derivation (PSA_KEY_USAGE_DERIVE), and not derive platform keys otherwise. For builtin keys that do not derive platform keys but are directly used, care must be taken with access control where multiple partitions have access to the same raw key material.

Mbed TLS transparent builtin keys

Mbed TLS does not natively support transparent builtin keys (transparent keys are keys where the key material is directly accessible by the PSA Crypto core), so some modifications had to be made. Opaque keyslots have the same basic structure as standard transparent key slots, and can be passed to the functions usually reserved for transparent keys, though this is a private implementation detail of the Mbed TLS library and is not specified in the driver interface. Therefore, the only modification required currently is to allow keys that have the location TFM_BUILTIN_KEY_LOADER_KEY_LOCATION to be passed to the functions that usually accept transparent keys only, i.e. with the location PSA_KEY_LOCATION_LOCAL_STORAGE. This is due to the fact that the standard assumption of the PSA Crypto core is that, if a driver that provides an additional location, will also provide dedicated cryptographic mechanisms to act on those keys, but this is not the case of the tfm_builtin_key_loader, as it just provides a mechanism to load keys (which act as a transparent key with local storage, once loaded), but Mbed TLS does not support such "transparent builtin key" concept. Note that the modifications on Mbed TLS are relying on non standard implementation details hence this particular integration can change between releases[3].

Using Opaque PSA crypto accelerators with TF-M

For platforms which have a cryptographic accelerator which has a corresponding Opaque PSA crypto accelerator driver, the TF-M builtin key loader driver can be disabled using the -DCRYPTO_TFM_BUILTIN_KEYS_DRIVER=OFF cmake option. The platform can then redefine the HAL function tfm_plat_builtin_key_get_desc_table_ptr to point to a table where the location and slot number of the keys corresponds instead to the opaque driver. The PSA driver wrapper will then route the calls into the opaque driver, with no other changes needed. If the description table is altered but the builtin key loader driver is not disabled, it is possible to mix software builtin keys with keys stored in opaque accelerators on a per-key level. Note that because the key policy enforcement via tfm_plat_builtin_key_get_desc_table_ptr is currently applied by the builtin key loader driver, other opaque drivers must apply either this policy or their own policy (Though this may be changed in future).

shawn.shan@arm.com

Background

In current TF-M log system, the SPM and Secure partitions share the same log APIs and implementations. While TF-M is keep evolving, the requirements for the log system has changed:

- Log level is required for both SPM and SP sides to output message in different scenarios.
- SPM only needs simple log format such as hex and string, while SP needs rich formatting.
- Distinctions on log output between SPM and SP are required.

A new log system is needed to separate the SPM and Secure partitions and to meet their different requirements.

Design

To allow customizable configurations, the log interfaces are defined as macros. The macros are easy to be forwarded or even empty. When SPM trying to output message and a value, it relies on a wrapper function, and finally output the formatted message by the HAL API.

The design principles of TF-M log system:

- Configurable log levels.
- Separated SPM and SP log implementations.
- Platforms provide log HAL implementations.

SPM Log System

Level Control

Three log levels for SPM log system are defined:

- TFM_SPM_LOG_LEVEL_DEBUG
- TFM_SPM_LOG_LEVEL_INFO
- TFM_SPM_LOG_LEVEL_ERROR
- TFM_SPM_LOG_LEVEL_SILENCE

Then a macro TFM_SPM_LOG_LEVEL is defined as an indicator, it should be equal to one of the four log levels.

API Definition

The following three APIs LOG APIs output the given 'msg' with hexadecimal formatted 'val' together. These APIs provide constrained ability to output numbers inside SPM. The 'msg' can be skipped with giving an empty string like "". And these APIs supports constant 'msg' string only, giving a runtime string as parameter 'msg' would potentially cause a runtime error.

SPMLOG_DBGMSGVAL(msg, val);

SPMLOG_INFMSGVAL(msg, val);

SPMLOG_ERRMSGVAL(msg, val);

A C-function needs to work as an underlayer for these APIs as string formatting is required. Check 'spm_log_msgval' for details.

```
/**
 * brief Output the given message plus one value as hexadecimal. The message
 *       can be skipped if the 'msg' is 'NULL' or 'len' equals 0. The
 *       formatted hexadecimal string for 'value' has a '0x' prefix and
 *       leading zeros are not stripped. This function rely on HAL API
 *       'tfm_hal_output_spm_log' to output the formatted string.
 *
 * \param[in]  msg    A string message
 * \param[in]  len    The length of the message
 * \param[in]  value  A value need to be output
 *
 * \retval >=0        Number of chars output.
 * \retval <0         TFM HAL error code.
 */
int32_t  spm_log_msgval(const char *msg, size_t len, uint32_t value)
```

The following three APIs output a message in string.

SPMLOG_DBGMSG(msg);

SPMLOG_INFMSG(msg);

SPMLOG_ERRMSG(msg);

Here is a table about the effective APIs with different SPM log level.

	TFM_SPM_LOG_LEV	TFM_SPM_LOG_LE	TFM_SPM_LOG_LE\	TFM_SPM_LOG_LEVEL_SILENCE
SPM-LOG_DBGMSG'	Yes	No	No	No
SPM-LOG_INFMSGV	Yes	Yes	No	No
SPM-LOG_ERRMSG\	Yes	Yes	Yes	No
SPM-LOG_DBGMSG	Yes	No	No	No
SPM-LOG_INFMSG	Yes	Yes	No	No
SPM-LOG_ERRMSG	Yes	Yes	Yes	No

HAL API

Define HAL API for SPM log system:

```
/* SPM log HAL API */
int32_t tfm_hal_output_spm_log(const char *str, uint32_t len);
```

Take debug message as an example:

```
/* For debug message */
#define SPMLOG_DBGMSG(msg) tfm_hal_output_spm_log(msg, sizeof(msg))
/* For debug message with a value */
#define SPMLOG_DBGMSGVAL(msg, val) spm_log_msgval(msg, sizeof(msg), val)
```

Partition Log System

Partition log outputting required rich formatting in particular cases. There is a customized print inside TF-M(printf), and it is wrapped as macro.

Level Control

Three log levels for partition log system are defined:

- TFM_PARTITION_LOG_LEVEL_DEBUG
- TFM_PARTITION_LOG_LEVEL_INFO
- TFM_PARTITION_LOG_LEVEL_ERROR
- TFM_PARTITION_LOG_LEVEL_SILENCE

Then a macro TFM_PARTITION_LOG_LEVEL is defined as an indicator. It should be equal to one of the four log levels and it is an overall setting for all partitions.

Log Format

Compared to SPM, SP log API supports formatting. Similar to printf, these log APIs use a format outputting to output various type of data:

```
%d - decimal signed integer
%u - decimal unsigned integer
%x - hex(hexadecimal)
%c - char(character)
%s - string
```

API Definition

Define partition log APIs:

LOG_DBGFMT(...);

LOG_INFFMT(...);

LOG_ERRFMT(...);

Here is a table about the effective APIs with different partition log level.

	TFM_PARTITION_LO(	TFM_PARTITION_LC	TFM_PARTITION_LO(	TFM_PARTITION_LOG_LEVEL_SILENC
LOG_DB(	Yes	No	No	No
LOG_INF	Yes	Yes	No	No
LOG_ERI	Yes	Yes	Yes	No

HAL API

Please refers to the HAL design document.

Log Devices

In most of the cases, a serial device could be used as a log device. And in other particular cases, a memory-based log device could be applied as well. These log device interfaces are abstracted into HAL APIs.

Note: It is not recommended to re-use the same HAL for both SPM and SP log outputting especially when SPM and SP run under different privileged level, which makes them have a different information confidential level. Unless:

- The SPM log outputting would be disabled as silence in the release version.

Requirements

PSA Certified Level 3 Lightweight Protection Profile[1] requires protection against physical attacks. This includes protection against manipulation of the hardware and any data, undetected manipulation of memory contents, physical probing on the chip's surface. The RoT detects or prevents its operation outside the normal operating conditions (such as voltage, clock frequency, temperature, or external energy fields) where reliability and secure operation has not been proven or tested.

Note: Mitigation against certain level of physical attacks is a mandatory requirement for PSA Level 3 certification. The *TF-M countermeasures against physical attacks* discussed below doesn't provide mitigation against all the physical attacks considered in scope for PSA L3 certification. Please check the Protection Profile document for an exhaustive list of requirements.

Physical attacks

The goal of physical attacks is to alter the expected behavior of a circuit. This can be achieved by changing the device's normal operating conditions to untested operating conditions. As a result a hazard might be triggered on the circuit level, whose impact is unpredictable in advance but its effect can be observed. With frequent attempts, a weak point of the system could be identified and the attacker could gain access to the entire device. There is a wide variety of physical attacks, the following is not a comprehensive list rather just give a taste of the possibilities:

- Inject a glitch into the device power supply or clock line.
- Operate the device outside its temperature range: cool down or warm it up.
- Shoot the chip with an electromagnetic field. This can be done by passing current through a small coil close to the chip surface, no physical contact or modification of the PCB (soldering) is necessary.
- Point a laser beam on the chip surface. It could flip bits in memory or a register, but precise knowledge of chip layout and design is necessary.

The required equipment and cost of these attacks varies. There are commercial products to perform such attacks. Furthermore, they are shipped with a scripting environment, good documentation, and a lot of examples. In general, there is a ton of videos, research paper and blogs about fault injection attacks. As a result the threshold, that even non-proficient can successfully perform such attack, gets lower over time.

Effects of physical attacks in hardware and in software execution

[1] PSA Certified Level 3 Lightweight Protection Profile

The change in the behavior of the hardware and software cannot be seen in advance when performing a physical attack. On circuit-level they manifest in bit faults. These bit faults can cause varied effects in the behavior of the device micro-architecture:

- Instruction decoding pipeline is flushed.
- Altering instructions when decoding.
- Altering data when fetching or storing.
- Altering register content, and the program counter.
- Flip bits in register or memory.

These phenomenons happen at random and cannot be observed directly but the effect can be traced in software execution. On the software level the following can happen:

- A few instructions are skipped. This can lead to taking different branch than normal.
- Corrupted CPU register or data fetch could alter the result of a comparison instruction. Or change the value returned from a function.
- Corrupted data store could alter the config of peripherals.
- Very precise attacks with laser can flip bits in any register or in memory.

This is a complex domain. Faults are not well-understood. Different fault models exist but all of them target a specific aspect of fault injection. One of the most common and probably the easily applicable fault model is the instruction skip.

Mitigation against physical attacks

The applicability of these attacks highly depends on the device. Some devices are more sensitive than others. Protection is possible at hardware and software levels as well.

On the hardware level, there are chip design principles and system IPs that are resistant to fault injection attacks. These can make it harder to perform a successful attack and as a result the chip might reset or erase sensitive content. The device maker needs to consider what level of physical attack is in scope and choose a SoC accordingly.

On top of hardware-level protection, a secondary protection layer can be implemented in software. This approach is known as “defence in depth”.

Neither hardware nor software level protection is perfect because both can be bypassed. The combination of them provides the maximum level of protection. However, even when both are in place, it is not certain that they provide 100% protection against physical attacks. The best of what is to achievable to harden the system to increase the cost of a successful attack (in terms of time and equipment), thereby making it non profitable to perform them.

Software countermeasures against physical attacks

There are practical coding techniques which can be applied to harden software against fault injection attacks. They significantly decrease the probability of a successful attack:

- Control flow monitor

  To catch malicious modification of the expected control flow. When an important portion of a program is executed, a flow monitor counter is incremented. The program moves to the next stage only if the accumulated flow monitor counter is equal to an expected value.

- Default failure

  The return value variable should always contain a value indicating failure. Changing its value to success is done only under one protected flow (preferably protected by double checks).

- Complex constant

  It is hard to change a memory region or register to a pre-defined value, but usual boolean values (0 or 1) are easier to manipulate.

- Redundant variables and condition checks

  To make branch condition attack harder it is recommended to check the relevant condition twice (it is better to have a random delay between the two comparisons).

- Random delay

  Successful fault injection attacks require very precise timing. Adding random delay to the code execution makes the timing of an attack much harder.

- Loop integrity check

  To avoid to skip critical loop iterations. It can weaken the cryptographic algorithms. After a loop has executed, check the loop counter whether it indeed has the expected value.

- Duplicated execution

  Execute a critical step multiple times to prevent fault injection from skipping the step. To mitigate multiple consecutive fault injections, random delay can be inserted between duplicated executions.

These techniques should be applied in a thoughtful way. If it is applied everywhere then it can result in messy code that makes the maintenance harder. Code must be analysed and sensitive parts and critical call path must be identified. Furthermore, these techniques increase the overall code size which might be an issue on the constrained devices.

Currently, compilers are not providing any support to implement these countermeasures automatically. On the contrary, they can eliminate the protection code during optimization. As a result, the C level protection does not add any guarantee about the final behavior of the system. The effectiveness of these protections highly depends on the actual compiler and the optimization level. The compiled assembly code must be visually inspected and tested to make sure that proper countermeasures are in-place and perform as expected.

TF-M Threat Model against physical attacks

Physical attack target

A malicious actor performs physical attack against TF-M to retrieve assets from device. These assets can be sensitive data, credentials, crypto keys. These assets are protected in TF-M by proper isolation.

For example, a malicious actor can perform the following attacks:

- Reopen the debug port or hinder the closure of it then connect to the device with a debugger and dump memory.
- Bypass secure boot to replace authentic firmware with a malicious image. Then arbitrary memory can be read.
- Assuming that secure boot cannot be bypassed then an attacker can try to hinder the setup of the memory isolation hardware by TF-M *Secure Partition Manager* (SPM) and manage to execute the non-secure image in secure state. If this is achieved then still an exploitable vulnerability is needed in the non-secure code which can be used to inject and execute arbitrary code to read the assets.
- Device might contain unsigned binary blob next to the official firmware. This can be any data, not necessarily code. If an attacker manages to replace this data with arbitrary content (e.g. a NOP slide leading to a malicious code) then they can try to manipulate the program counter to jump to this area before setting up the memory isolation.

Assumptions on attacker capability

It is assumed that the attacker owns the following capabilities to perform physical attack against devices protected by TF-M.

- Has physical access to the device.
- Able to access external memory, read and possibly tamper it.
- Able to load arbitrary candidate images for firmware upgrade.
- Able to manage that bootloader tries to upgrade the arbitrary image from staging area.
- Able to inject faults on hardware level (voltage or power glitch, EM pulse, etc.) to the system.
- Precise timing of fault injection is possible once or a few times, but in general the more intervention is required for a successful attack the harder will be to succeed.

It is out of the scope of TF-M mitigation if an attacker is able to directly tamper or disclose the assets. It is assumed that an attacker has the following technical limitations.

- No knowledge of the image signing key. Not able to sign an arbitrary image.
- Not able to directly access to the chip through debug port.
- Not able to directly access internal memory.
- No knowledge of the layout of the die or the memory arrangement of the secure code, so precise attack against specific registers or memory addresses are out of scope.

Physical attack scenarios against TF-M

Based on the analysis above, a malicious actor may perform physical attacks against critical operations in *SPE* workflow and critical modules in TF-M, to indirectly gain unauthenticated accesses to assets.

Those critical operations and modules either directly access the assets or protect the assets from disclosure. Those operations and modules can include:

- Image validation in bootloader
- Isolation management in TF-M, including platform specific configuration
- Cryptographic operations
- TF-M Secure Storage operations
- PSA client permission check in TF-M

The detailed scenarios are discussed in following sections.

Physical attacks against bootloader

Physical attacks may bypass secure image validation in bootloader and a malicious image can be installed.

The countermeasures is bootloader specific implementation and out of the scope of this document. TF-M relies on MCUboot by default. MCUboot has already implemented countermeasures against fault injection attacks[3].

Physical attacks against TF-M SPM

TF-M SPM initializes and manages the isolation configuration. It also performs permission check against secure service requests from PSA clients.

Static isolation configuration

[3] MCUboot fault injection mitigation

It is TF-M SPM's responsibility to build up isolation during the initialization phase. If this is missed or not done correctly then it might be possible for non-secure code to access some secure memory area or an external device can access assets in the device through a debug port.

Therefore, hindering the setup of memory or peripheral isolation hardware is an obvious candidate for physical attacks. The initialization phase has a constant time execution (like the previous boot-up state), therefore the timing of the attack is simpler, compared to cases when secure and non-secure runtime firmware is up-and-running for a while and IRQs make timing unpredictable.

Some examples of attacking isolation configuration are shown in the list below.

- Hinder the setting of security regions. Try to execute non-secure code as secure.
- Manipulate the setting of secure regions, try to extend the non-secure regions to cover a memory area which otherwise is intended to be secure area.
- Hinder the setting of isolation boundary. In this case vulnerable ARoT code has access to all memory.
- Manipulate peripheral configuration to give access to non-secure code to a peripheral which is intended to be secure.

PSA client permission checks

TF-M SPM performs several permission checks against secure service requests from a PSA client, such as:

- Check whether the PSA client is a non-secure client or a secure client

  NS client's PSA client ID is negative. NS client is not allowed to directly access secure areas. A malicious actor can inject faults when TF-M SPM authenticates a NS client. It may manipulate TF-M to accept it as a secure client and allow the NS client to access assets.

- Memory access checks

  TF-M SPM checks whether the request has correct permission to access a secure memory area. A malicious actor can inject faults when TF-M SPM checks memory access permission. It may skip critical check steps or corrupt the check result. Thereby a malicious service request may pass TF-M memory access check and accesses assets which it is not allowed to.

The physical attacks mentioned above relies on the a malicious NS application or a vulnerable RoT service to start a malicious secure service request to access the assets. The malicious actor has to be aware of the accurate timing of dealing with the malicious request in TF-M SPM. The timing can be affected by other clients and interrupts. It should be more difficult than pure fault injection.

Dynamic isolation boundary configuration

Physical attack may affect the isolation boundary setting during TF-M context switch, especially in Isolation Level 3. For example:

- A fault injection may cause TF-M SPM to skip clear privileged state before switching in an ARoT service.
- A fault injection may cause TF-M SPM to skip updating MPU regions and therefore the next RoT service may access assets belonging to a previous one.

However, it is much more difficult to find out the accurate timing of TF-M context switch, compared to other scenarios in TF-M SPM. It also requires a vulnerable RoT service to access assets after fault injection.

Physical attacks against TF-M Crypto service

Since crypto operations are done by mbedTLS library or by a custom crypto accelerator engine and its related software driver stack, the analysis of physical attacks against crypto operations

is out-of-scope for this document. However, in general the same requirements are applicable for the crypto, to be compliant with PSA Level 3 certification. That is, it must be resistant against physical attacks. So crypto software and hardware must be hardened against side-channel and physical attacks.

Physical attacks against Secure Storage

Physical attacks against Internal Trusted Storage

Based on the assumption in *Assumptions on attacker capability*, a malicious actor is unable to directly retrieve assets via physical attacks against *Internal Trusted Storage* (ITS).

Instead, a malicious actor can inject faults into isolation configuration of ITS area in TF-M SPM to gain the access to assets stored in ITS. Refer to *Physical attacks against TF-M SPM* for details.

Physical attacks against Protected Storage

Based on the assumption in *Assumptions on attacker capability*, a malicious actor can be able to directly access external storage device. Therefore *Protected Storage* (PS) shall enable encryption and authentication by default to detect tampering with the content in external storage device.

A malicious actor can also inject faults into isolation configuration of PS and external storage device peripherals in TF-M SPM to gain the access to assets stored in PS. Refer to *Physical attacks against TF-M SPM* for details.

It is out of the scope of TF-M to fully prevent malicious actors from directly tampering with or retrieving content stored in external storage devices.

Physical attacks against platform specific implementation

Platform specific implementation includes critical TF-M HAL implementations. A malicious actor can perform physical attack against those platform specific implementations to bypass the countermeasures in TF-M common code.

Platform early initialization

TFM provides a HAL API for platforms to perform HW initialization before SPM initialization starts. The system integrator is responsible to implement this API on a particular SoC and harden it against physical attacks:

```
enum tfm_hal_status_t tfm_hal_platform_init(void);
```

The API can have several initializations on different modules. The system integrator can choose to even harden some of these initializations functions within this platform init API. One of the examples is the debug access setting.

Debug access setting

TF-M configures debug access according to device lifecycle and accessible debug certificates. In general, TF-M locks down the debug port if the device is in secure production state. The system integrator can put the settings into an API and harden it against physical attacks.

Platform specific isolation configuration

TFM SPM exposes a HAL API for static and dynamic isolation configuration. The system integrator is responsible to implement these API on a particular SoC and harden it against physical attacks.

```
enum tfm_hal_status_t tfm_hal_set_up_static_boundaries(void);
enum tfm_hal_status_t tfm_hal_bind_boundary(const struct partition_load_info_t *p_ldinf,
                                            uintptr_t *p_boundary);
```

Memory access check

TFM SPM exposes a HAL API for platform specific memory access check. The system integrator is responsible to implement this API on a particular SoC and harden it against physical attacks.

```
tfm_hal_status_t tfm_hal_memory_check(uintptr_t boundary,
                                      uintptr_t base,
                                      size_t size,
                                      uint32_t access_type);
```

TF-M countermeasures against physical attacks

This section propose a design of software countermeasures against physical attacks.

Fault injection hardening library

There is no open-source library which implements generic mitigation techniques listed in *Software countermeasures against physical attacks*. TF-M project implements a portion of these techniques. TF-M software countermeasures are implemented as a small library Fault Injection Hardening (FIH) in TF-M code base. A similar library was first introduced and tested in the MCUboot project (version 1.7.0)[2] which TF-M relies on.

The FIH library is put under TF-M lib/fih/.

The implementation of the different techniques was assigned to fault injection protection profiles. Four profiles (OFF, LOW, MEDIUM, HIGH) were introduced to fit better to the device capability (memory size, TRNG availability) and to protection requirements mandated by the device threat model. Fault injection protection profile is configurable at compile-time, default value: OFF.

Countermeasure profiles and corresponding techniques are listed in the table below.

Countermeasure	Profile LOW	Profile MEDIUM	Profile HIGH	Comments
Control flow monitor	Y	Y	Y	
Failure loop hardening	Y	Y	Y	
Complex constant		Y	Y	
Redundant variables and checks		Y	Y	
Random delay			Y	Implemented, but depends on HW capability

Similar to MCUboot, four profiles are supported. It can be configured at build time by setting (default is OFF):

-DTFM_FIH_PROFILE=<OFF, LOW, MEDIUM, HIGH>

How to use FIH library

As analyzed in *TF-M Threat Model against physical attacks*, this section focuses on integrating FIH library in TF-M SPM to mitigate physical attacks.

- Identify critical function call path which is mandatory for configuring isolation or debug access. Change their return types to FIH_RET_TYPE and make them return with FIH_RET. Then call them with FIH_CALL. These macros are providing the extra checking functionality (control flow monitor, redundant checks and variables, random delay, complex constant) according to the profile settings. More details about usage can be found here: trusted-firmware-m/lib/fih/inc/fih.h

[2] MCUboot project

Take simplified TF-M SPM initialization flow as an example:

```
main()
  |
  |--> tfm_core_init()
  |          |
  |          |--> tfm_hal_set_up_static_boundaries()
  |          |                |
  |          |                |--> platform specific isolation impl.
  |          |
  |          |--> tfm_hal_platform_init()
  |                           |
  |                           |--> platform specific init
  |
  |--> During each partition initialization
             |
             |--> tfm_hal_bind_boundary()
                           |
                           |--> platform specific peripheral isolation impl.
```

- Might make the important setting of peripheral config register redundant and verify them to match expectations before continue.
- Implements an extra verification function which checks the critical hardware config before secure code switches to non-secure. Proposed API for this purpose:

```
fih_int tfm_hal_verify_static_boundaries(void);
```

This function is intended to be called just after the static boundaries are set up and is responsible for checking all critical hardware configurations. The goal is to catch if something is missed and act according to system policy. The introduction of one more checking point requires one more intervention with precise timing. The system integrator is responsible to implement this API on a particular SoC and harden it against physical attacks. Make sure that all platform dependent security feature is properly configured.

- The most powerful mitigation technique is to add random delay to the code execution. This makes the timing of the attack much harder. However it requires an entropy source. It is recommended to use the HIGH profile when hardware support is available. There is a porting API layer to fetch random numbers in FIH library:

```
void fih_delay_init(void);
uint8_t fih_delay_random(void);
```

- Similar countermeasures can be implemented in critical steps in platform specific implementation.

  Take memory isolation settings on AN521 platform as an example. The following hardware components are responsible for memory isolation in a SoC, which is based on SSE-200 subsystem. System integrators must examine the chip specific memory isolation solution, identify the key components and harden the configuration of those. This list just serves as an example here for easier understanding:

  – Implementation Defined Attribution Unit (IDAU): Implementation defined, it can be a static config or dynamic. Contains the default security access permissions of the memory map.

  – SAU: The main module in the CPU to determine the security settings of the memory.

  – *MPC*: External module from the CPU point of view. It protects the non security aware memories from unauthenticated access. Having a properly configured MPC significantly increases the security of the system.

  – *PPC*: External module from the CPU point of view. Protects the non security aware peripherals from unauthenticated access.

– MPU: Protects memory from unprivileged access. ARoT code has only a restricted access in secure domain. It mitigates that a vulnerable or malicious ARoT partition can access to device assets.

The following AN521 specific isolation configuration functions shall be hardened against physical attacks.

```
sau_and_idau_cfg()
mpc_init_cfg()
ppc_init_cfg()
```

Some platform specific implementation rely on platform standard device driver libraries. It can become much more difficult to maintain drivers if the standard libraries are modified with FIH library. Platform specific implementation can implement duplicated execution and redundant variables/ condition check when calling platform standard device driver libraries according to usage scenarios.

Impact on memory footprint

The addition of protection code against physical attacks increases the memory footprint. The actual increase depends on the selected profile and where the mitigation code is added.

Attack experiment with SPM

The goal is to bypass the setting of memory isolation hardware with simulated instruction skips in fast model execution (FVP_MPS2_AEMv8M) in order to execute the regular non-secure test code in secure state. This is done by identifying the configuration steps which must be bypassed to make this happen. The instruction skip simulation is achieved by breakpoints and manual manipulation of the program counter. The following steps are done on AN521 target, but this can be different on another target:

- Bypass the configuration of isolation HW: SAU, MPC.
- Bypass the setting of the PSP limit register. Otherwise, a stack overflow exception will happen. Because the secure PSP will be overwritten by the address of the non-secure stack and on this particular target the non-secure stack is on lower address than the value in the secure PSP_LIMIT register.
- Avoid the clearing of the least significant bit in the non-secure entry point, where BLXNS/BXNS is jumping to non-secure code. Having the least significant bit cleared indicates to the hardware to switch security state.

The previous steps are enough to execute the non-secure Reset_Handler() in secure state. Usually, RTOS is executing on the non-secure side. In order to properly boot it up further steps are needed:

- Set the S_VTOR system register to point the address of the NS Vector table. Code is executed in secure state therefore when an IRQ hit then the handler address is fetched from the table pointed by S_VTOR register. RTOS usually do an SVC call at start-up. If S_VTOR is not modified then SPM's SVC handler will be executed.
- TBC: RTX osKernelStart still failing.

The bottom line is that in order to execute the regular non-secure code in secure state the attacker need to interfere with the execution flow at many places. Successful attack can be made even harder by adding the described mitigation techniques and some random delays.

Contribution Guidelines

Contributing Process

Contributions to the TF-M project need to follow the process below.

Note: Please contact TF-M mailing list for any question.

- It is recommended to subscribe to TF-M mailing list via this page.
- Refer to the *Roadmap* or send a mail to the TF-M mailing list to get the latest status and plan of TF-M.
- Follow *Design Proposal Guideline* to propose your design.
- Follow guidelines below to prepare the patch:
  - Clone the TF-M code on your own machine from TF-M git repository.
  - Follow the TF-M getting started, *Build Instructions Coding Guide* for the TF-M project.
  - Make your changes in logical chunks to help reviewers. Each commit should be a separate review and either work properly or be squashed after the review and before merging.
  - Follow *Documentation Contribution Guidelines* to update documentation in `docs` folder if needed.
  - Test your changes and add details to the commit description.
  - The code is accepted under *Developer Certificate of Origin (DCO)*. Use `git commit -s` to add a `Signed-off-by` trailer at the end of the commit log message. See git-commit for details.
  - Ensure that each changed file has the correct copyright and license information. Files that entirely consist of contributions to this project should have a copyright notice and BSD-3-Clause SPDX license identifier of the form as shown in *License*. Files that contain changes to imported Third Party IP files should retain their original copyright and license notices.

    Contributors can add the following copyright note, (whilst) it is suggested to update copyright note only for *major*, non-trivial changes.

    ```
    Copyright (c) XXXX[-YYYY], <OWNER>. All rights reserved.
    ```

    where XXXX is the year of first contribution and YYYY is the optional year of most recent contribution. <OWNER> is your or your company name.
  - Add a Change-Id to the commit message, which can be generated any way you like (e.g. from the SHA of the commit). It is suggested to clone repositories with commit-msg hook. The commit-msg hook attaches Change-Id automatically. Take trusted-firmware-m as an example.
- Submit your patch for review. Refer to Uploading Changes for details of uploading patch.
- Add relevant *code owner(s)* for reviewing the patch.
- You may be asked to provide further details or make additional changes.
- You can discuss further with code owner(s) and maintainer(s) directly via TF-M mailing list if necessary.

- If multiple patches are linked in a chain then code owners and maintainers should review and merge individual patches when they are ready, rather than waiting for the entire chain to be reviewed. If multiple patches are intended to be merged together then authors shall use topics or explicitly mention that in the commit message.
- Click Allow-CI +1 button on Gerrit page to run CI to validate your patch. Your patch shall pass CI successfully before being merged. Code owner(s) and maintainer(s) may ask for additional test.
- Once the change is approved by code owners, the patch will be merged by the maintainer.

Code Review Guideline

The purpose of this document is to clarify design items to be reviewed during the code review process.

Please contact *maintainers* or write an e-mail thread on the TF-M mailing list for any questions.

List of the guidelines

The prerequisites before going to the review stage:

- Read the *Contributing Process* to know basic concepts.
- Read the *Source Structure* for structure related reference.

The review guidelines consist of these items:

- *Exceptions*.
- *Non-source items*.
- *Namespace*.
- *Assembler code*.
- *Include*.
- *Auto-doc*.
- *Commit Message*.

Note: Each guideline item is assigned with a unique symbol in the format Rx.y, while x and y are numeric symbols. These symbols are created for easy referencing during the code review process.

Exceptions

Files under listed folders are fully or partially imported from 3rd party projects, these files follow the original project defined guidelines and styles:

Important:

- R1.1 ext and its subfolders.

Non-source items

For all non-source files such as build system files or configuration files:

Important:

- R2.1 Follow the existing style while making changes.

Namespace

TF-M assign the namespace to files and symbols for an easier code reading. The symbol here includes functions, variables, types and MACROs. The prerequisites:

Important:

- R3.1 Follow the documents or specifications if they propose namespaces ('psa_' for PSA defined items E.g.,). Ask the contributor to tell the documents or specifications if the reviewer is not sure about a namespace.
- R3.2 Assign TF-M specific namespace 'tfm_' or 'TFM_' for symbols implementing TF-M specific features. Ask the contributor to clarify the purpose of the patch if the reviewer is not sure about the namespace.

For the sources out of the above prerequisites (R3.1 and R3.2):

Important:

- R3.3 Do not assign a namespace for source files.
- R3.4 Assigning a namespace for interface symbols is recommended. The namespace needs to be expressed in one word to be followed by other words into a phrase can represent the functionalities implemented. One word naming is allowed if the namespace can represent the functionality perfectly.
- R3.5 Assign a namespace for private symbols is NOT recommended.
- R3.6 Do not assign characters out of alphabets as the leading character.

Examples:

```
/* R3.1 FILE: s/spm/core/psa_client.c */

/* R3.2 FILE: s/spm/core/tfm_secure_context.c */

/* R3.4 FILE: s/spm/core/spm.c, 'spm\_' as the namespace */
void spm_init(void);

/* R3.5 FILE: s/spm/core/main.c */
static void init_functions(void);

/* R3.6 Not permitted: */
/* static uint32_t ___count; */
```

Assembler code

Important:

- R4.1 Pure assembler sources or inline assembler code are required to be put under the platform-independent or architecture-independent folders. The logic folders should not contain any assembler code, referring to external MACRO wrapped assembler code is allowed. Here is one example of the logic folder:
  - 'secure_fw/spm'.

Examples:

```
/*
 * R4.1 The following MACRO is allowed to be referenced under
 * 'secure_fw/spm'
 */
#define SVC(code) __asm volatile("svc  %0", ::"I"(code))
```

Include

This chapter describes the placement of the headers and including. There are two types of headers: The interface headers contain symbols to be shared between modules and the private headers contain symbols only for internal usage.

Important:

- R5.1 Put the interface header of one module in the include folder under the root of this module. Deeper sub-folders can not have include folders, which means only one include is allowed for one module.
- R5.2 Creating sub-folders under include to represent the more granular scope of the interfaces is allowed.
- R5.3 private header can be put at the same place with the implementation sources for the private symbols contained in the header. It also can be put at the place where the sources need it. The latter is useful when some "private header" contains abstracted interfaces, but these interfaces are not public interfaces so it won't be put under "include" folder.
- R5.4 Use <> when including public headers.
- R5.5 Use "" when including private headers.
- R5.6 The module's include folder needs to be added into referencing module's header searching path.
- R5.7 The module's include folder and the root folder needs to be added into its own header searching path and apply a hierarchy including with folder name.
- R5.8 Path hierarchy including is allowed since there are sub-folders under include folder and the module folder.
- R5.9 The including statement group order: the beginning group contains toolchain headers, then follows the public headers group and finally the private headers group.
- R5.10 The including statement order inside a group: Compare the include statement as strings and sort by the string comparison result.
- R5.11 The header for the referenced symbol or definition must be included even this header is included inside one of the existing included headers. This improves portability in case the existing header implementation changed.

Examples:

```
/*
 * The structure:
 *   module_a/include/func1.h
 *   module_a/include/func2/fmain.h
 *   module_a/func1.c
 *   module_a/func2/fmain.c
 *   module_b/include/funcx.h
 *   module_b/include/funcy/fmain.h
```

(continues on next page)

(continued from previous page)

```
 *   module_b/funcx.c
 *   module_b/funcxi.h
 *   module_b/funcy/fmain.c
 *   module_b/funcy/fsub.c
 *   module_b/funcy/fsub.h
 * Here takes module_b/funcx.c as example:
 */
#include <func1.h>
#include <func2/fmain.h>
#include <funcx.h>
#include "funcxi.h"
#include "funcy/fsub.h"
```

Auto-doc

Auto document system such as doxygen is useful for describing interfaces. While it would be a development burden since the details are described in the design documents already. The guidelines for auto-doc:

Important:

- R6.1 Headers and sources under these folders need to apply auto-doc style comments: *include.
- R6.2 Developers decide the comment style for sources out of listed folders.

Commit Message

TF-M has the requirements on commit message:

Important:

- R7.1 Assign correct topic for a patch. Check the following table.

Topic	Justification
Boot	*bl2/** or *bl1/**
Build	For build system related purpose.
Docs	All *.rst changes.
Dualcpu	Dual-cpu related changes.
HAL	Generic HAL interface/implementation changes.
Interface	Interface changes, either Non-source and secure.
Pack	For packing purpose.
Platform	Generic platform related changes under *platform/**.
Platform Name	Specific platform changes.
Partition	Multiple partition related changes.
Partition Name	Specific partition related changes.
Service	Multiple service related changes.
Service Name	Specific service related changes.
SPM	*secure_fw/spm/**
SPRTL	*secure-fw/partitions/lib/runtime/**
Tool	*tools* folder or *tf-m-tools* repo

Note: Ideally, one topic should cover one specific type of changes. For crossing topic changes, check the main part of the change and use the main part related topic as patch topic. If there is

no suitable topics to cover the change, contact the community for an update.

Copyright (c) 2020-2022, Arm Limited. All rights reserved.

Trusted Firmware-M (TF-M) is an open govcommunity project. All contributions are ultimately merged by the maintainers listed below. Technical ownership of most parts of the codebase falls on the code owners listed below. An acknowledgement from these code owners is required before the maintainers merge a contribution.

More details may be found in the Project Maintenance Process document.

Yet another coding standard :)

Warning: Every rule has an exception so if you disagree or dislike then reach out!

The coding style of TF-M project is based on Linux coding style but there are updates for domain specific conventions as listed below.

TF-M also reuses code from other SW projects, e.g. CMSIS_5, which means some areas of code may have different styles. We use common sense approach and new code may inherit coding style from external projects but it needs to remain within clear scope.

The guidance below is provided as a help. It isn't meant to be a definitive list.

As implied in the *contributing guide* maintainers have the right to decide on what's acceptable in case of any divergence.

Warning: Text files do not fall within these rules as they may require different formatting.

Consistent style

The code needs to be consistent with itself, so if existing code in the file violates listed coding style rules then it is better to follow existing style in the file and not break consistency by following the rules listed here.

You may need to add a comment in the commit description to clarify this.

List of rules

- Use 4 spaces indentation. No tabs.
- Use lower_case_with_underscore for filenames, variable and function names.
- Use standard types e.g. uint32_t, uint16_t, uint8_t, int32_t etc.
- Use uintptr_t type when representing addresses as numbers.
- Use static for all private functions and variables.
- Use void argument if your function doesn't contain any argument.
- Use C90 /* */ for comments rather than C99 //
- No trailing spaces in code.
- Keep up to 100 characters per line but 140 chars can be accepted exceptionally.
- Open curly brace { at the same if/else/while/for/switch statement line.
- Use curly braces { } for one line statement bodies also.

- Put open curly brace in the line below the function header.
- Order function parameters so that input params are before output params.
- Declare local variables at the beginning of the function.
- Define macros in all caps i.e. CAPITAL_WITH_UNDERSCORE.
- Use typedefs **ONLY** for function prototype declarations.
- Type definitions in lower_case_with_underscore ended by _t.
- Do not use typedef for other constructs as it obfuscates code.
- Do not use bitfields.
- Use static for all global variables to reduce the variable scope.
- Use enumeration for error codes to keep the code readable.
- Use descriptive variable and functions names.
- Put the correct license header at the beginning of the file.
- Keep the files (.h/.c) self-contained, i.e. put include dependencies in the file.
- Put appropriate header define guard in .h files: ___HEADER_NAME___. Any divergence from this rules should be clearly documented.
- In a .c file, #include it's own header file first.
- Document all the public functions in the header file only.
- Document all the private functions in the source file only.
- Add "extern C " definition for C++ support in the header files.
- In the switch statement, aligned cases with the switch keyword.
- For enums, use upper case letters with digits and underscore only.
- Do not code while eating.

Documentation Contribution Guidelines

The Trusted Firmware-M project uses Sphinx to generate the Official Documentation from Restructed Text *.rst* source files,

The aim is to align as much as possible with the official Python Documentation Guidelines while keeping the consistency with the already existing files.

The guidance below is provided as a help. It is not meant to be a definitive list.

Overview

The following short-list provides a quick summary of the rules.

- If the patch modifies a present file, the file's style should be followed
- If creating a new file, *integration guide* can be used as a reference.
- When a new style is to be expressed, consult the Python Documentation Guidelines

List of rules

The following rules should be considered:

1. H1 document title headers should be expressed by # with over-line (rows on top and bottom) of the text
2. Only ONE H1 header should allowed per document, ideally placed on top of the page.
3. H2 headers should be expressed by * with over-line
4. H2 header's text should be UNIQUE in per document basis
5. H3 headers should be expressed by an underline of '='
6. H4 headers should be expressed by an underline of '-'
7. H3 and H4 headers have no limitation about naming. They can have similar names on the same document, as long as they have different parents.
8. H5 headers should be expressed by an underline of '^'
9. H5 headers will be rendered in document body but not in menus on the navigation bar
10. Do not use more than 5 levels of heading
11. When writing guides, which are expected to be able to be readable by command line tools, it would be best practice to add long complicated tables, and UML diagrams in the bottom of the page and using internal references(auto-label)
12. No special formatting should be allowed in Headers (code, underline, strike-through etc)
13. Long URLs and external references should be placed at the bottom of the page and referenced in the body of the document
14. New introduced terms and abbreviations should be added to Glossary and directly linked by the *:term:* notation across all documents using it.

Platform Documentation

The Documentation Build system provides an interface with the platform directory allowing maintainers to bundle platform specific documentation. Platforms are grouped by vendor. **This behaviour needs to be explicitly enabled for each vendor's space** by providing the *<vendor>/index.rst* (responsible for generating the *Platform Index File*) and adding a table of contents entry for the corresponding vendor's space. The format and structure of this entry is not strictly defined, and allows flexible control of vendor's and platform's documentation space. Follow the *Platform Documentation* document for more details.

Common Use Cases

The section below describes with examples, a rule compliant implementation for most common documentation elements.

Headers

```
####################
Document Title (H1)
####################

**********
Chapter Title (H2)
**********

Chapter Section (H3)
==========

Chapter Sub-Section (H4)
----------
```

(continues on next page)

(continued from previous page)

```
Subsection of Chapter sub-section (H5)
~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
```

Code Blocks

The recommendation for code content, is to use the explicit code-block directive, ideally with a defined lexer for the language the block contains.

A list of compatible lexers can be found at Pygments Lexers

```
.. code-block:: bash

   ls
   pwd

.. code-block:: doscon

   dir

.. code-block:: c

   static struct rn_object_t;

.. code-block:: python3

   print("Hello TF-M")
```

Restructured Text supports implicit code-blocks by indenting a section of text, surrounded by new lines. While this formatting is allowed, it should be avoided if possible.

```
The quick brown fox jumps over the lazy dog

   ls
   pwd
```

Note: Mixing two different code-block formats in the same document will break the whole document's rendering. When editing an existing document, please follow the existing format.

New documents should always use the explicit format.

Tables

For adding new tables the *table::* notation should be used.

```
.. table:: Components table
   :widths: auto

   +-------------+-------------+------------+
   | **Title A** | **Title B** | **Title C** |
   +=============+=============+============+
   | Text A      | Text B      | Text C     |
   +-------------+-------------+------------+
```

While the equivalent simple table code will render correctly in the output, it will not be added to the index (So it cannot be referenced if needed)

```
+-------------+-------------+------------+
| **Title A** | **Title B** | **Title C** |
+=============+=============+============+
```

(continues on next page)

(continued from previous page)

```
| Text A       | Text B       | Text C      |
+--------------+--------------+-------------+
```

Other types of tables such as list-tables and csv-tables are also permitted, as seen on /getting_started/tfm_getting_started and /releases/1.0

External Links

External links should be placed in the bottom of a document.

```
The quick brown fox jumps over the lazy dog according to `Link_A`_

.. _Link_A: https://www.aaa.org
.. _Link_B: https://www.bbb.org

--------------

*Copyright (c) XYZ *
```

Creating in-line links is permitted, but should be avoided if possible. It should be only used for consistency purposes or for a small ammount of short links.

```
The quick brown fox jumps over the lazy dog according to `Link_A <https://www.aaa.org>`_
```

If for the purposes of content, a link is to be referenced by multiple labels, internal linking is the recommended approach.

```
The quick brown fox jumps over the lazy dog according to `Link_A_New`_

.. _Link_A: https://www.aaa.org
.. _Link_A_New: `Link_A`_

--------------

*Copyright (c) XYZ *
```

Document Links

A document included in the documentation can be referenced by the *doc:* notation

```
:doc:`integration guide </integration_guide/tfm_integration_guide>`
```

The path is relative to the root of the Trusted Firmware-M code.

Trusted Firmware-M project is spread among multiple repositories: Trusted Firmware-M, TF-M Tests, TF-M Tools and TF-M Extras. Every repository has its own documentation, and since *v2.0.0*, they can be found under *Links*.

Using Intersphinx, it is now possible to use cross-reference roles from Sphinx to reference documentation from different projects (repositories), like TF-M Tests. Referencing documentation using the *doc:* notation is preferred and helps to avoid broken cross-references if the link of the document changes.

For example, to get this: Adding TF-M Regression Test Suite; the Restructed Text would look like this:

```
:doc:`Adding TF-M Regression Test Suite <TF-M-Tests:tfm_test_suites_addition>`
```

As can be seen, it is quite similar to cross-referencing in Sphinx, except the path to the document is preceded with the external project name. For TF-M Tests, it is TF-M-Tests. The names of other

projects configured to be referenced using Intersphinx can be seen in the conf.py file under intersphinx_mapping.

Reference specific section of a document

In order to reference a specific section of a document, up to level 4 headers (if they are included in the index), the *ref:* keyword can be used

```
:ref:`docs/getting_started/tfm_getting_started:Tool & Dependency overview`
```

This can also be used to quickly scroll to the specific section of the current document. This technique can be used to add complex table in the bottom of a document and create clickable quick access references to it for improved user experience.

Glossary term

For technical terms and abbreviations, the recommended guidance is to add an entry to the *Glossary of terms and abbreviations* and refer to it, using the *term:* directive

```
HAL
Hardware Abstraction Layer
   Interface to abstract hardware-oriented operations and provides a set of
   APIs to the upper layers.

.....

As described in the design document :term:`HAL` abstracts the
hardware-oriented and platform specific
.......
```

Note: The ":term:" directive does not work when used in special formatting. Using *:term:*HAL*** **will not link to the glossary term**.

Design proposal guideline

The design proposal guideline specifies the steps to propose and upload design proposals to TF-M. Those steps are lightweight and flexible to make sure that contributors can focus more on actual code implementation and iteration.

The guideline encourages developers to share design proposal via TF-M mailing list[1] and TF-M technical forum (tech forum)[2]. The design details can be discussed via code reviews of actual implementations.

Typical steps are shown as the diagram below.

[1] TF-M mailing list
[2] TF-M technical forum

```
@startuml

title Design proposal process

[*] --> propose : Non-trivial changes

state "Propose general ideas" as propose {
  state "TF-M mailing list" as mail_list : Contributors send emails to mailing list\nto describe the design.
  state "TF-M tech forum" as tech_forum : Contributors present the design\nin tech forum.

  [*] --> mail_list
  [*] --> tech_forum
}

note bottom of propose : Optional but strongly recommended

[*] --> upload
note right of upload : No prerequisites
propose --> upload

state "Upstream changes" as upload : Contributors upstream code patch\nand integration guide to gerrit.
state "Code review" as review : Reviewer review changes of\ncode and documents.\nChanges pass␣
↪verifications.
state "Broadcast patches" as broadcast : Contributors ask for review\nin mailing list.
state "Approve and merge" as approve : Code owners approve changes.\nMaintainers merge patches.

upload --> broadcast : Optional
upload --> review

broadcast --> review
review --> review : Update implementation
review --> approve
approve --> [*]

@enduml
```

Discussion in TF-M mailing list and tech forum

It is **highly recommended** to propose and discuss designs in TF-M mailing list or TF-M tech forum, before or while the code implementation is under review.

It is efficient and flexible to directly discuss design proposal via TF-M mailing list and TF-M tech forum. Contributors can receive quick and broad feedback from TF-M community.

Although it is optional to present the ideas in mailing list or tech forum, it will help reviewers understand the design much better and expedite the code review process.

Code review of details

It is straightforward and convenient for contributors and reviewers to deliberate over design and implementation details via code review.

Contributors can implement their design proposal and upstream the patch set to TF-M gerrit[3] for code review. For non-trivial changes or new major features, it is **strongly suggested** to propose the design to TF-M mailing list and tech forum in advance.

Contributors don't have to wait for any approvals before upstreaming patches, even if the changes are non-trivial. No formal design document in advance is required anymore.

The review process is the same as the general one[4], with some specific requirements:

[3] TF-M gerrit
[4] *Contributing process*

- Contributors can send an email to TF-M mailing list to ask for review.
- If it requires additional reviewers besides code owners and maintainers, contributors shall add the specific reviewers in the review list.
- Authors shall clearly specify the design purpose and briefly describe the implementation in the commit message.
- Authors shall put essential comments and notes in code for the code changes.

Code owners and maintainers may require contributors to further verify the implementation besides normal per-patch CI test. Contributors shall provide the verification results as requested.

Integration guide and manual

Contributors can create an integration guide or a user manual to describe how to integrate the new features related to the design proposal.

Contributors shall update the corresponding documents if the design changes existing implementation.

TF-M-Tests Documents TF-M Tests

Trusted Firmware-M Tests

The Trusted Firmware-M(TF-M) Tests repo is meant to hold various tests for the Trusted Firmware-M. The TF-M tests mainly focus on functionalities of various TF-M componentes such as the TF-M SPM and various Secure Partitions.

The TF-M eRPC Test Framework

The TF-M eRPC Test Framework is an Remote Procedure Call (RPC) framework for testing purpose. It's based on the eRPC system. It is an additional framework to the existing one for running NS test suites. It enables you to run test codes on host machines as if they were running on the device. It has the following advantages.

- Off-load test codes from device to host

  Arm M-profile devices usually have limited flash storage which can only fit limited test suites. With test codes running on hosts you can run far more tests than on the devices.

- Less frequent image downloading for test code development.

  As the test codes run on the host, you don't need to update the image on device when you update test codes.

- Host can get test pass or failure directly from the return codes.

  This would be helpful for test automation because you don't need to parse the test logs.

How Does It Work

Originally, the NS tests are executed in the NSPE of the device. The NS image on the device contains the test codes, which calls into TF-M through the PSA client APIs.

With the eRPC test framework, the NS tests code are executed on the host machine. The NSPE of device side does not run the test codes anymore. When the tests call the PSA client APIs, they call into the eRPC framework. The eRPC framework communicates with the NSPE on the device, which calls into TF-M through the PSA client APIs.

The prototypes of the PSA client APIs are the same while the implementations are different. Refer to the following sections for more details.

The Stucture

The following diagram shows the software structure.

- eRPC Framework

  The eRPC framework system

- eRPC Client Shim

  The eRPC generated shim layer of remote APIs for clients. It serializes the identifier of the API and its parameters into a stream of bytes and transports to the server through a communication channel such as UART and TCP/IP. The codes are generated by the erpcgen tool.

- eRPC Server Shim

  The generated shim layer of the server. It registers a callback function to the eRPC framework. When the framework receives any requests from the client, it calls the callback function. The callback unserializes the bytes streams to determine what API to call and then invoke it with the corresponding parameters from the bytes streams. And then it returns the results to the client in the reverse routine.

- API Wrapper

  Part of the parameters of $\mathrm{psa\_call}$ API is not supported by eRPC directly, thus an API wrapper is required to transform the $\mathrm{in\_vec/out\_vec}$ structures to the eRPC supported data types. The wrapper API is named as $\mathrm{erpc\_psa\_call}$.

On the client side, the wrapper implements the psa_call which calls the erpc_psa_call in the client shim layer. On the server side, the wrapper implements the erpc_psa_call which is called by the shim layer. The erpc_psa_call then calls the psa_call.

- Test Suites

  Can be the existing TF-M regression tests or any other tests that interact with TF-M using the PSA Client APIs.

- Host App

  Initializes the eRPC client and starts test suites.

- Target App

  Initializes the eRPC server and listens for requests from the client.

Supported APIs

The APIs supported for doing RPC are the PSA Client APIs because they are the lowest level APIs that interact with TF-M. You can build lots of test suites upon them. You can also add your own APIs in the tfm.erpc file. Please refer to IDL Reference for the syntax of the file.

API Grouping

PSA client APIs are categorised into common APIs and connection-based service APIs. Connection-based APIs are available when there are connection-based services in the TF-M. So in the eRPC integration, the APIs are also split into two groups so that the shim layer of the APIs can be separated into different files as well. Then build systems can decide which source files to build based on the existence of connection-based services.

Common APIs:

- psa_framework_version()
- psa_version()
- psa_call()

Connection-based specific:

- psa_connect()
- psa_close()

Transportation

On device side, only UART transportation is supported in NSPE. For the host side, both UART and TCP are supported. The TCP transportation support is basically for fast models where UART data are transferred between a TCP/IP socket on the host and a serial port on the target. See the fast model reference guide for more details.

Platform Integration

First, the UART drivers of platforms shall support TX/RX control feature. The TF-M build system provides a CONFIG_ENABLE_NS_UART_TX_RX_CONTROL option to enable or disable the TX/RX control feature and it is disabled by default. When the eRPC test framework is enabled, the CONFIG_ENABLE_NS_UART_TX_RX_CONTROL will be enabled automatically.

Secondly, platforms need to create their folders under the erpc/platform and then create the config_erpc_target.h to specify the UART port drivers for eRPC transportation.

```
#define ERPC_UART          Driver_USART0
```

Note: The folder structure in erpc/platform must be the same as the platform/ext/target of TF-M repo.

It's recommended to use a different UART to the stdio UART. If the same UART is used for both, then the TF-M logs (both SPM and Secure Partitions) must be disabled. Otherwise, the eRPC transportation might fail.

Application Integration

The TF-M eRPC test framework provides two CMake libraries for integration. One is the erpc_client, the other is the erpc_server. Both include the eRPC framework, the shim layers, API wrappers and expose an initialization API for client and server respectively.

The initialization does not include the initialization of the transportation layer because it is use case specific which kind of transportation is used. So it is the client and server's responsibilities to initialize the transportation layers and pass them to the erpc_client and erpc_server.

TF-M provides a app/erpc_app.c as the default server application which initializes the UART transportation and starts the eRPC server.

A config option CONFIG_TFM_ERPC_TEST_FRAMEWORK is provided to enable the eRPC framework on device (server) side. The default server will be built and developers only need to focus on the client application developments.

In summary, on the server side, you only need to build with the CONFIG_TFM_ERPC_TEST_FRAMEWORK enabled. On the client side, you must

- Initializes the transportation layer using eRPC provided APIs.
- Call the initialization function provided by TF-M eRPC test framework with the transportation instance initialized above.
- Develop the application code
- Building with CMake
  - add_subdirectory with the erpc/client
  - link the erpc_client library

There is an example at erpc/host_example for reference.

Adding partitions for regression tests

Introduction

Some test group may need specific test services. These test services may support one or more groups thus developers shall determine the proper test scope. Currently, TF-M test services are located under tf-m-tests/test/secure_fw.

Folder name	Description
test/secure_fw/suites/<suite>/service	Test service divided into corresponding suite subdirectories.
test/secure_fw/common_test_service	Common test services.

Implementation

Adding a test partition to provide test services is same as adding a secure partition, generally the process can be referenced from the document Adding Secure Partition.

Test Partition Specific Manifest Attributes

Each test service must have resource requirements declared in a manifest file, the contents of test services are the same as secure partitions, but their locations are different. Test service manifests shall be set in tf-m-tests/test/secure_fw/tfm_test_manifest_list.yaml.

There are some test purpose attributes in Secure Partition manifests that are **NOT** compatible with FF-M. They should be used in Test Partitions only.

weak_dependencies

A TF-M regression test Partition calls other RoT services for test. But it can still run other tests if some of the RoT services are disabled. TF-M defines a "weak_dependencies" attribute in partition manifests of regression test partitions to describe test service access to other RoT services. It *shall* be only used for TF-M regression test services.

model

A TF-M regression test Partition may support both the SFN and IPC model. The actual model being used follows the SPM backend enabled.

The TF-M build system supports this by allowing Secure Partitions to set the model attribute to dual. The manifest tool will then change it to the corresponding value according to the current backend selected.

The Test Partitions use the following definitions to know what model is being built:

- <<partition_name>>_MODEL_IPC, 1 if IPC model is used.
- <<partition_name>>_MODEL_SFN, 1 if SFN model is used.

Test service implementation

Test service of individual test

An individual test dedicated test service should be put under the corresponding test folder test/secure_fw/suites/<test_name>.

add_subdirectory(suites/<test_name>/<service_dir>) shall be added into tf-m-tests/test/secure_fw/secure_tests.cmake to make sure that the test service is built with secure side configuration.

Common test service

If a new test service is required by multiple test suites, the code should be put under test/secure_fw/common_test_services. If the new test suite relies on a common test service, please make sure that the build implementation of the test service is linked correctly, including the header files and libraries.

Introduction of TF-M regression tests

TF-M regression tests test whether changes to TF-M code work as expected. A new regression test can consist of following 3 components:

1. test suite: A series of tests of a certain function.

2. test case: A specific test instance in test suites.
3. test service or partition: Optional secure services or partitions to support related test suites.

Source structure

Folder name	Description
test/bl1	TF-M bl1 test suites source code.
test/bl2	TF-M bL2 test suites source code.
test/config	The CMAKE test configurations files.
test/framework	Source code for test framework code, managing test suites.
test/secure_fw/suites	Test suites divided into subdirectories.
test/secure_fw/suites/<suite>/service	Test service divided into corresponding suite subdirectories.
test/secure_fw/common_test_service	Common test services.

Adding a new test suite

This section introduces how to add a new test suite and control its compilation with a test configuration in tests_reg/test repository.

Source code

The test suite example subdirectory named <test_name> is located under the path tests_reg/test/secure_fw/suites. If the new test suite includes both non-secure and secure parts, the source code shall be divided shared code and specific code. An example test suite folder can be organized as the figure below.

```
.
   <test_name>_tests_common.c
   non_secure
|      CMakeLists.txt
       <test_name>_ns_interface_testsuite.c
       <test_name>_ns_tests.h
   secure
       CMakeLists.txt
       <test_name>_s_interface_testsuite.c
       <test_name>_s_tests.h
```

Creating test configurations

A test configuration controls whether one or multiple test suites are enabled. The doc TF-M Build Instructions. shows some test configurations which are already supported in current TF-M.

Developers shall assign corresponding test configurations to control the test suites.

Naming test configurations

The test configurations of example test suites are TEST_NS_<TEST_NAME> in non-secure and TEST_S_<TEST_NAME> in secure.

Note: The test configurations must be named with the prefixes TEST_S_ and TEST_NS_, for secure regression tests and non-secure regression tests respectively. Otherwise, tests_reg/test build system may not recognize it.

Setting test configurations

When the test configurations have dependencies, the default value need to be set. The setting is performed in following four steps.

1. Command line input: The configuration can be enabled or disabled by the command -DTEST_NS_<TEST_NAME>=ON/OFF -DTEST_S_<TEST_NAME>=ON/OFF, and the value cannot be changed throughout the whole compilation of TF-M tests.
2. tests_reg/test/config/config.cmake: The test configurations shall be OFF if its dependencies are not supported. The dependencies are probably from:
    1. TF-M partitions configurations like TFM_PARTITION_CRYPTO, TFM_PARTITION_INITIAL_ATTESTATION, etc.
    2. TF-M build mode configuration like CONFIG_TFM_SPM_BACKEND.
    3. TF-M other configurations like TFM_PARTITION_FIRMWARE_UPDATE, etc.
3. tests_reg/test/config/default_ns_test_config.cmake or tests_reg/test/config/default_s_test_config.cmake: It is required to give the default value of the new test configuration in these two files when TEST_NS or TEST_S is ON. The recommended value is ON unless the single test's code or data size is very large.
4. tests_reg/test/config/default_test_config.cmake: It is required to give the default value of the new test configuration in the file when both TEST_NS and TEST_S are OFF. The default value must be OFF.

Note: The test configurations must be set as CACHE value in CMAKE files. The CACHE set cannot replace the value from command line, see Set Cache Entry.

Checking test configurations

The new test configurations must be checked by function tfm_invalid_config() if they have any dependence. The value comes from command line may be wrong when the dependencies are conflicting.

Implement necessary checks in tests_reg/test/config/check_config.cmake.

Export TF-M configurations

If the new test depends on some TF-M configurations, export their value via tests_reg/test/config/config_ns_tests.cmake.in. TF-M secure build will install config_ns_tests.cmake and export configuration values. tf-m-tests non-secure build will include config_ns_tests.cmake and receive TF-M configuration values.

Applying test configurations

The mission of test configurations is to control the build. They are applied in test/secure_fw/suites/<test_name>/CMakeLists.txt like the example below.

```
if (NOT TEST_NS_<TEST_NAME> AND NOT TEST_S_<TEST_NAME>)
    return()
endif()

######################### Non Secure ################################
↪############

if (TEST_NS_<TEST_NAME>)
    add_library(tfm_test_suite_<test_name>_ns STATIC EXCLUDE_FROM_ALL)
    # target_sources()
    # target_include_directories()
    target_compile_definitions(tfm_test_suite_<test_name>_ns
```

(continues on next page)

(continued from previous page)

```
        INTERFACE
            TEST_NS_<TEST_NAME>
    )
    # target_link_libraries()
endif()

########################## Secure ###################################
↪##############

if (TEST_S_<TEST_NAME>)
    add_library(tfm_test_suite_<test_name>_s STATIC EXCLUDE_FROM_ALL)
    # target_sources()
    # target_include_directories()
    target_compile_definitions(tfm_test_suite_<test_name>_s
        INTERFACE
            TEST_S_<TEST_NAME>
    )
    # target_link_libraries()
endif()
```

The function target_compile_definitions will export the macros TEST_NS_<TEST_NAME> or TEST_S_<TEST_NAME> into source code. and in the file tests_reg/test/framework/non_secure_suites.c or tests/framework/secure_suites.c, the definitions of these macros will be checked, and then the head file will be included and test cases will be registered if the macro is defined.

```
#ifdef TEST_NS_<TEST_NAME>
#include "<test_name>_ns_tests.h"
#endif

static struct test_suite_t test_suites[] = {
/* Non-secure example test cases */
    // ......
#ifdef TEST_NS_<TEST_NAME>
    {&register_testsuite_ns_<test_name>_interface, 0, 0, 0},
#endif
};
```

```
#ifdef TEST_S_<TEST_NAME>
#include "<test_name>_s_tests.h"
#endif

static struct test_suite_t test_suites[] = {
/* Secure example test cases */
    // ......
#ifdef TEST_S_<TEST_NAME>
    {&register_testsuite_s_<test_name>_interface, 0, 0, 0},
#endif
};
```

Note: On most platforms non-secure tests and secure tests run on the same CPU core, but dual-core platform is an exception. So secure test library and secure services shall be linked together in the file tests_reg/test/test/secure_fw/secure_tests.cmake. Thus they can be built on secure CPU core and non-secure tests library and RTOS are built on non-secure CPU core.

```
# ...
if (TEST_S_<TEST_NAME>)
    add_library(tfm_test_suite_<test_name>_s STATIC EXCLUDE_FROM_ALL)
```

(continues on next page)

(continued from previous page)

```
endif()
```

Adding a new test case in test suite

The test cases usually express as a function in source code. They will be added into an array with structure type called test_t defined in tests_reg/test/test/framework/test_framework.h.

```
struct test_t {
    TEST_FUN * const test;          /*!< Test function to call */
    const char *name;               /*!< Test name */
    const char *desc;               /*!< Test description */
};
```

For example, a new test case called TFM_NS_<TEST_NAME>_TEST_1001 is created and the function tfm_<test_name>_test_1001 needs to be defined in file <test_name>_ns_interface_testsuite.c. Then the function shall be appended into the array which will be quoted in function register_testsuite_ns_<test_name>_interface. See the reference code below.

```
/* List of test cases */
static void tfm_<test_name>_test_1001(struct test_result_t *ret);

/* Append test cases */
static struct test_t <test_name>_tests[] = {
    {&tfm_<test_name>_test_1001, "TFM_NS_<TEST_NAME>_TEST_1001",
    "Example test case"},
};

/* Register test case into test suites */
void register_testsuite_ns_<test_name>_interface(struct test_suite_t *p_test_suite)
{
    uint32_t list_size;

    list_size = (sizeof(<test_name>_tests) / sizeof(<test_name>_tests[0]));

    set_testsuite("<TEST_NAME> non-secure interface test (TFM_NS_<TEST_NAME>_TEST_1XXX)",
                  <test_name>_tests, list_size, p_test_suite);
}

static void tfm_<test_name>_test_1001(struct test_result_t *ret)
{
   /* test case code */
}
```

Adding test services

Some test group may need specific test services. These test services may support one or more groups thus developers shall determine the proper test scope. Refer to *Adding partitions for regression tests* to get more information.

Out-of-tree regression test suites

TF-M supports out-of-tree regression test suites build, whose source code folder is outside tf-m-tests repo. There are two configurations for developers to include the source code.

- EXTRA_NS_TEST_SUITE_PATH

  An absolute directory of the out-of-tree non-secure test suite source code folder. TF-M build system searches CMakeLists.txt of non-secure test suite in the source code folder.

- EXTRA_S_TEST_SUITE_PATH

  An absolute directory of the out-of-tree secure test suite source code folder.

Example usage

Take non-secure test as an example in tf-m-extras. A single out-of-tree test suite folder can be organized as the figure below:

```
extra_ns
  CMakeLists.txt
  ns_test.c
  ns_test_config.cmake
```

In the example above, EXTRA_NS_TEST_SUITE_PATH in the build command can be specified as listed below.

```
-DEXTRA_NS_TEST_SUITE_PATH=<Absolute-path-extra-test-folder>
```

Coding instructions

This is a demo of source code so the structure has been simplified. Files like .c and .h can be expanded to src and include folders respectively. The CMakeLists.txt is required in the root path and ns_test_config.cmake is optional.

Header Files

The header file extra_ns_tests.h must be included by out-of-tree source code. This file contains the declaration of void register_testsuite_extra_ns_interface(struct test_suite_t *p_test_suite).

Source code

To connect the out-of-tree source code and regression test framework, the test case function/functions must be defined first. An example format is:

```
void ns_test(struct test_result_t *ret)
{
    /* Add platform specific non-secure test suites code here. */

    ret->val = TEST_PASSED;
}
```

This function follows the standard TF-M test case function prototype.

Note: Extra tests can have one or more test cases. This is simplified example so only one test case is added.

After ns_test() is defined, a structure variable need to be created like:

```
static struct test_t plat_ns_t[] = {
    {&ns_test, "TFM_EXTRA_TEST_1001",
     "Extra Non-Secure test"},
};
```

It will be used by function register_testsuite_extra_ns_interface() to register the test by calling the set_testsuite() function:

```
void register_testsuite_extra_ns_interface(struct test_suite_t *p_test_suite)
{
    uint32_t list_size;

    list_size = (sizeof(plat_ns_t) /
                 sizeof(plat_ns_t[0]));

    set_testsuite("Extra Non-Secure interface tests"
                  "(TFM_NS_EXTRA_TEST_1XXX)",
                  plat_ns_t, list_size, p_test_suite);
}
```

The platform initialization code can be added in this function because it runs before ns_test().

Note: Function register_testsuite_extra_ns_interface() is declared in tf-m-tests repository without definition. It is supplied to out-of-tree source code and need to be defined with no change of its format, like returns error code and parameter name.

CMakeLists.txt

After extra test suite file were created they must be linked to tfm_test_suite_extra_ns CMAKE target:

```
target_sources(tfm_test_suite_extra_ns
    PRIVATE
        ${CMAKE_CURRENT_SOURCE_DIR}/ns_test.c
)
```

ns_test_config.cmake

The CMAKE configuration file is optional. If out-of-tree source already exists another configuration file, a new one can be ignored.

Psa-arch-tests Documents PSA Architecture Tests

PSA APIs Architecture Test Suite

Introduction

Arm *Platform Security Architecture* (PSA) is a holistic set of threat models, security analyses, hardware and firmware architecture specifications, and an open source firmware reference implementation. PSA provides a recipe, based on industry best practice, that allows security to be consistently designed in, at both a hardware and firmware level. One of the PSA goals is to make IoT security easier and quicker for everyone. This means having reliable, consistent APIs and useful built-in security functions for device manufacturers and the developer community. These PSA APIs provides a consistent developer experience, hiding the underlying complexity of the security system.

For more information, visit the PSA Webpage.

Architecture test suite

The current implementation of the architecture test suite contains tests for PSA Firmware Framework and PSA Certified APIs specifications. The tests are available as open source. The tests and the corresponding abstraction layers are available with an Apache v2.0 license, allowing external contribution.

PSA Firmware Framework (PSA-FF)

The test suite for this specification is located in the **ff** directory of this repository. See the *PSA Firmware Framework README* file for more details.

PSA Certified APIs

The test suite for this specification is located in the **dev_apis** directory of this repository. See the *PSA Certified APIs README* file for more details.

License

Arm PSA test suite is distributed under Apache v2.0 License.

Feedback, contributions, and support

- For feedback, use the GitHub Issue Tracker that is associated with this repository.
- For support, send an email to support-psa-arch-tests@arm.com with details.
- Arm licensees can contact Arm directly through their partner managers.
- Arm welcomes code contributions through GitHub pull requests.

3.2 Motor Control

3.2.1 FreeMASTER

Communication Driver User Guide

Introduction

What is FreeMASTER? FreeMASTER is a PC-based application developed by NXP for NXP customers. It is a versatile tool usable as a real-time monitor, visualization tool, and a graphical control panel of embedded applications based on the NXP processing units.

This document describes the embedded-side software driver which implements an interface between the application and the host PC. The interface covers the following communication:

- **Serial** UART communication either over plain RS232 interface or more typically over a USB-to-Serial either external or built in a debugger probe.
- **USB** direct connection to target microcontroller
- **CAN bus**
- **TCP/IP network** wired or WiFi

- **Segger J-Link RTT**
- **JTAG** debug port communication
- ...and all of the above also using a **Zephyr** generic drivers.

The driver also supports so-called "packet-driven BDM" interface which enables a protocol-based communication over a debugging port. The BDM stands for Background Debugging Module and its physical implementation is different on each platform. Some platforms leverage a semi-standard JTAG interface, other platforms provide a custom implementation called BDM. Regardless of the name, this debugging interface enables non-intrusive access to the memory space while the target CPU is running. For basic memory read and write operations, there is no communication driver required on the target when communicating with the host PC. Use this driver to get more advanced FreeMASTER protocol features over the BDM interface. The driver must be configured for the packet-driven BDM mode, in which the host PC uses the debugging interface to write serial command frames directly to the target memory buffer. The same method is then used to read response frames from that memory buffer.

Similar to "packet-driven BDM", the FreeMASTER also supports a communication over [J-Link RTT]((https://www.segger.com/products/debug-probes/j-link/technology/about-real-time-transfer/) interface defined by SEGGER Microcontroller GmbH for ARM CortexM-based microcontrollers. This method also uses JTAG physical interface and enables high-speed real time communication to run over the same channel as used for application debugging.

Driver version 3 This document describes version 3 of the FreeMASTER Communication Driver. This version features the implementation of the new Serial Protocol, which significantly extends the features and security of its predecessor. The new protocol internal number is v4 and its specification is available in the documentation accompanying the driver code.

Driver V3 is deployed to modern 32-bit MCU platforms first, so the portfolio of supported platforms is smaller than for the previous V2 versions. It is recommended to keep using the V2 driver for legacy platforms, such as S08, S12, ColdFire, or Power Architecture. Reach out to FreeMASTER community or to the local NXP representative with requests for more information or to port the V3 driver to legacy MCU devices.

Thanks to a layered approach, the new driver simplifies the porting of the driver to new UART, CAN or networking communication interfaces significantly. Users are encouraged to port the driver to more NXP MCU platforms and contribute the code back to NXP for integration into future releases. Existing code and low-level driver layers may be used as an example when porting to new targets.

Note: Using the FreeMASTER tool and FreeMASTER Communication Driver is only allowed in systems based on NXP microcontroller or microprocessor unit. Use with non-NXP MCU platforms is **not permitted** by the license terms.

Target platforms The driver implementation uses the following abstraction mechanisms which simplify driver porting and supporting new communication modules:

- **General CPU Platform** (see source code in the src/platforms directory). The code in this layer is only specific to native data type sizes and CPU architectures (for example; alignment-aware memory copy routines). This driver version brings two generic implementations of 32-bit platforms supporting both little-endian and big-endian architectures. There are also implementations customized for the 56F800E family of digital signal controllers and S12Z MCUs. **Zephyr** is treated as a specific CPU platform as it brings unified user configuration (Kconfig) and generic hardware device drivers. With Zephyr, the transport layer and low-level communication layers described below are configured automatically using Kconfig and Device Tree technologies.
- **Transport Communication Layer** - The Serial, CAN, Networking, PD-BDM, and other methods of transport logic are implemented as a driver layer called FMSTR_TRANSPORT with a

uniform API. A support of the Network transport also extends single-client modes of operation which are native for Serial, USB and CAN by a concept of multiple client sessions.

- **Low-level Communication Driver** - Each type of transport further defines a low-level API used to access the physical communication module. For example, the Serial transport defines a character-oriented API implemented by different serial communication modules like UART, LPUART, USART, and also USB-CDC. Similarly, the CAN transport defines a message-oriented API implemented by the FlexCAN or MCAN modules. Moreover, there are multiple different implementations for the same kind of communication peripherals. The difference between the implementation is in the way the low-level hardware registers are accessed. The *mcuxsdk* folder contains implementations which use MCUXpresso SDK drivers. These drivers should be used in applications based on the NXP MCUXpresso SDK. The "ampsdk" drivers target automotive-specific MCUs and their respective SDKs. The "dreg" implementations use a plain C-language access to hardware register addresses which makes it a universal and the most portable solution. In this case, users are encouraged to add more drivers for other communication modules or other respective SDKs and contribute the code back to NXP for integration.

  The low-level drivers defined for the Networking transport enable datagram-oriented UDP and stream TCP communication. This implementation is demonstrated using the lwIP software stack but shall be portable to other TCP/IP stacks. It may sound surprisingly, but also the Segger J-Link RTT communication driver is linked to the Networking transport (RTT is stream oriented communication handled similarly to TCP).

Replacing existing drivers For all supported platforms, the driver described in this document replaces the V2 implementation and also older driver implementations that were available separately for individual platforms (PC Master SCI drivers).

Clocks, pins, and peripheral initialization The FreeMASTER communication driver is only responsible for runtime processing of the communication and must be integrated with an user application code to function properly. The user application code is responsible for general initialization of clock sources, pin multiplexers, and peripheral registers related to the communication speed. Such initialization should be done before calling the FMSTR_Init function.

It is recommended to develop the user application using one of the Software Development Kits (SDKs) available from third parties or directly from NXP, such as MCUXpresso SDK, MCUXpresso IDE, and related tools. This approach simplifies the general configuration process significantly.

MCUXpresso SDK The MCUXpresso SDK is a software package provided by NXP which contains the device initialization code, linker files, and software drivers with example applications for the NXP family of MCUs. The MCUXpresso Config Tools may be used to generate the clock-setup and pin-multiplexer setup code suitable for the selected processor.

The MCUXpresso SDK also contains this FreeMASTER communication driver as a "middleware" component which may be downloaded along with the example applications from https://mcuxpresso.nxp.com/en/welcome.

MCUXpresso SDK on GitHub

The FreeMASTER communication driver is also released as one of the middleware components of the MCUXpresso SDK on the GitHub. This release enables direct integration of the FreeMASTER source code Git repository into a target applications including Zephyr applications.

FreeMASTER in Zephyr

The FreeMASTER middleware repository can be used with MCUXpresso SDK as well as a Zephyr module. Zephyr-specific samples which include examples of Kconfig and Device Tree configurations for Serial, USB and Network communications are available in separate repository. West manifest in this sample repository fetches the full Zephyr package including the FreeMASTER middleware repository used as a Zephyr module.

Example applications MCUX SDK Example applications

There are several example applications available for each supported MCU platform.

- **fmstr_uart** demonstrates a plain serial transmission, typically connecting to a computer's physical or virtual COM port. The typical transmission speed is 115200 bps.
- **fmstr_can** demonstrates CAN bus communication. This requires a suitable CAN interface connected to the computer and interconnected with the target MCU using a properly terminated CAN bus. The typical transmission speed is 500 kbps. A FreeMASTER-over-CAN communication plug-in must be used.
- **fmstr_usb_cdc** uses an on-chip USB controller to implement a CDC communication class. It is connected directly to a computer's USB port and creates a virtual COM port device. The typical transmission speed is above 1 Mbps.
- **fmstr_net** demonstrates the Network communication over UDP or TCP protocol. Existing examples use lwIP stack to implement the communication, but in general, it shall be possible to use any other TCP/IP stack to achieve the same functionality.
- **fmstr_wifi** is the fmstr_net application modified to use a WiFi network interface instead of a wired Ethernet connection.
- **fmstr_rtt** demonstrates the communication over SEGGER J-Link RTT interface. Both fmstr_net and fmstr_rtt examples require the FreeMASTER TCP/UDP communication plug-in to be used on the PC host side.
- **fmstr_eonce** uses the real-time data unit on the JTAG EOnCE module of the 56F800E family to implement pseudo-serial communication over the JTAG port. The typical transmission speed is around 10 kbps. This communication requires FreeMASTER JTAG/EOnCE communication plug-in.
- **fmstr_pdbdm** uses JTAG or BDM debugging interface to access the target RAM directly while the CPU is running. Note that such approach can be used with any MCU application, even without any special driver code. The computer reads from and writes into the RAM directly without CPU intervention. The Packet-Driven BDM (PD-BDM) communication uses the same memory access to exchange command and response frames. With PD-BDM, the FreeMASTER tool is able to go beyond basic memory read/write operations and accesses also advanced features like Recorder, TSA, or Pipes. The typical transmission speed is around 10 kbps. A PD-BDM communication plug-in must be used in FreeMASTER and configured properly for the selected debugging interface. Note that this communication cannot be used while a debugging interface is used by a debugger session.
- **fmstr_any** is a special example application which demonstrates how the NXP MCUXpresso Config Tools can be used to configure pins, clocks, peripherals, interrupts, and even the FreeMASTER "middleware" driver features in a graphical and user friendly way. The user can switch between the Serial, CAN, and other ways of communication and generate the required initialization code automatically.

Zephyr sample spplications

Zephyr sample applications demonstrate Kconfig and Device Tree configuration which configure the FreeMASTER middleware module for a selected communication option (Serial, CAN, Network or RTT).

Refer to *readme.md* files in each sample directory for description of configuration options required to implement FreeMASTER connectivity.

Description

This section shows how to add the FreeMASTER Communication Driver into application and how to configure the connection to the FreeMASTER visualization tool.

Features The FreeMASTER driver implements the FreeMASTER protocol V4 and provides the following features which may be accessed using the FreeMASTER visualization tool:

- Read/write access to any memory location on the target.
- Optional password protection of the read, read/write, and read/write/flash access levels.
- Atomic bit manipulation on the target memory (bit-wise write access).
- Optimal size-aligned access to memory which is also suitable to access the peripheral register space.
- Oscilloscope access—real-time access to target variables. The sample rate may be limited by the communication speed.
- Recorder— access to the fast transient recorder running on the board as a part of the FreeMASTER driver. The sample rate is only limited by the MCU CPU speed. The length of the data recorded depends on the amount of available memory.
- Multiple instances of Oscilloscopes and Recorders without the limitation of maximum number of variables.
- Application commands—high-level message delivery from the PC to the application.
- TSA tables—describing the data types, variables, files, or hyperlinks exported by the target application. The TSA newly supports also non-memory mapped resources like external EEPROM or SD Card files.
- Pipes—enabling the buffered stream-oriented data exchange for a general-purpose terminal-like communication, diagnostic data streaming, or other data exchange.

The FreeMASTER driver features:

- Full FreeMASTER protocol V4 implementation with a new V4 style of CRC used.
- Layered approach supporting Serial, CAN, Network, PD-BDM, and other transports.
- Layered low-level Serial transport driver architecture enabling to select UART, LPUART, USART, and other physical implementations of serial interfaces, including USB-CDC.
- Layered low-level CAN transport driver architecture enabling to select FlexCAN, msCAN, MCAN, and other physical implementations of the CAN interface.
- Layered low-level Networking transport enabling to select TCP, UDP or J-Link RTT communication.
- TSA support to write-protect memory regions or individual variables and to deny the access to the unsafe memory.
- The pipe callback handlers are invoked whenever new data is available for reading from the pipe.
- Two Serial Single-Wire modes of operation are enabled. The “external” mode has the RX and TX shorted on-board. The “true” single-wire mode interconnects internally when the MCU or UART modules support it.

The following sections briefly describe all FreeMASTER features implemented by the driver. See the PC-based FreeMASTER User Manual for more details on how to use the features to monitor, tune, or control an embedded application.

Board Detection

The FreeMASTER protocol V4 defines the standard set of configuration values which the host PC tool reads to identify the target and to access other target resources properly. The configuration includes the following parameters:

- Version of the driver and the version of the protocol implemented.
- MTU as the Maximum size of the Transmission Unit (for example; communication buffer size).
- Application name, description, and version strings.
- Application build date and time as a string.
- Target processor byte ordering (little/big endian).
- Protection level that requires password authentication.
- Number of the Recorder and Oscilloscope instances.
- RAM Base Address for optimized memory access commands.

Memory Read

This basic feature enables the host PC to read any data memory location by specifying the address and size of the required memory area. The device response frame must be shorter than the MTU to fit into the outgoing communication buffer. To read a device memory of any size, the host uses the information retrieved during the Board Detection and splits the large-block request to multiple partial requests.

The driver uses size-aligned operations to read the target memory (for example; uses proper read-word instruction when an address is aligned to 4 bytes).

Memory Write

Similarly to the Memory Read operation, the Memory Write feature enables to write to any RAM memory location on the target device. A single write command frame must be shorter than the MTU to fit into the target communication buffer. Larger requests must be split into smaller ones.

The driver uses size-aligned operations to write to the target memory (for example; uses proper write-word instruction when an address is aligned to 4 bytes).

Masked Memory Write

To implement the write access to a single bit or a group of bits of target variables, the Masked Memory Write feature is available in the FreeMASTER protocol and it is supported by the driver using the Read-Modify-Write approach.

Be careful when writing to bit fields of volatile variables that are also modified in an application interrupt. The interrupt may be serviced in the middle of a read-modify-write operation and it may cause data corruption.

Oscilloscope

The protocol and driver enables any number of variables to be read at once with a single request from the host. This feature is called Oscilloscope and the FreeMASTER tool uses it to display a real-time graph of variable values.

The driver can be configured to support any number of Oscilloscope instances and enable simultaneously running graphs to be displayed on the host computer screen.

Recorder

The protocol enables the host to select target variables whose values are then periodically recorded into a dedicated on-board memory buffer. After such data sampling stops (either on a host request or by evaluating a threshold-crossing condition), the data buffer is downloaded to the host and displayed as a graph. The data sampling rate is not limited by the speed of the communication line, so it enables displaying the variable transitions in a very high resolution.

The driver can be configured to support multiple Recorder instances and enable multiple recorder graphs to be displayed on the host screen. Having multiple recorders also enables setting the recording point differently for each instance. For example; one instance may be recording data in a general timer interrupt while another instance may record at a specific control algorithm time in the PWM interrupt.

TSA

With the TSA feature, data types and variables can be described directly in the application source code. Such information is later provided to the FreeMASTER tool which may use it instead of reading symbol data from the application ELF executable file.

The information is encoded as so-called TSA tables which become direct part of the application code. The TSA tables contain descriptors of variables that shall be visible to the host tool. The descriptors can describe the memory areas by specifying the address and size of the memory block or more conveniently using the C variable names directly. Different set of TSA descriptors can be used to encode information about the structure types, unions, enumerations, or arrays.

The driver also supports special types of TSA table entries to describe user resources like external EEPROM and SD Card files, memory-mapped files, virtual directories, web URL hyperlinks, and constant enumerations.

TSA Safety

When the TSA is enabled in the application, the TSA Safety can be enabled and validate the memory accesses directly by the embedded-side driver. When the TSA Safety is turned on, any memory request received from the host is validated and accepted only if it belongs to a TSA-described object. The TSA entries can be declared as Read-Write or Read-Only so that the driver can actively deny the write access to the Read-Only objects.

Application commands

The Application Commands are high-level messages that can be delivered from the PC Host to the embedded application for further processing. The embedded application can either poll the status, or be called back when a new Application Command arrives to be processed. After the embedded application acknowledges that the command is handled, the host receives the Result Code and reads the other return data from memory. Both the Application Commands and the Result Codes are specific to a given application and it is user's responsibility to define them. The FreeMASTER protocol and the FreeMASTER driver only implement the delivery channel and a set of API calls to enable the Application Command processing in general.

Pipes

The Pipes enable buffered and stream-oriented data exchange between the PC Host and the target application. Any pipe can be written to and read from at both ends (either on the PC or the MCU). The data transmission is acknowledged using the special FreeMASTER protocol commands. It is guaranteed that the data bytes are delivered from the writer to the reader in a proper order and without losses.

Serial single-wire operation

The MCU Serial Communication Driver natively supports normal dual-wire operation. Because the protocol is half-duplex only, the driver can also operate in two single-wire modes:

- "External" single-wire operation where the Receiver and Transmitter pins are shorted on the board. This mode is supported by default in the MCU driver because the Receiver and Transmitter units are enabled or disabled whenever needed. It is also easy to extend this operation for the RS485 communication.
- "True" single-wire mode which uses only a single pin and the direction switching is made by the UART module. This mode of operation must be enabled by defining the FMSTR_SERIAL_SINGLEWIRE configuration option.

Multi-session support

With networking interface it is possible for multiple clients to access the target MCU simultaneously. Reading and writing of target memory is processed atomically so there is no risk of data corruption. The state-full resources such as Recorders or Oscilloscopes are locked to a client session upon first use and access is denied to other clients until lock is released..

Zephyr-specific

Dedicated communication task

FreeMASTER communication may run isolated in a dedicated task. The task automates the FMSTR_Init and FMSTR_Poll calls together with periodic activities enabling the FreeMASTER UI to fetch information about tasks and CPU utilization. The task can be started automatically or manually, and it must be assigned a priority to be able to react on interrupts and other communication events. Refer to Zephyr FreeMASTER sample applications which all use this communication task.

Zephyr shell and logging over FreeMASTER pipe

FreeMASTER implements a shell backend which may use FreeMASTER pipe as a I/O terminal and logging output. Refer to Zephyr FreeMASTER sample applications which all use this feature.

Automatic TSA tables

TSA tables can be declared as "automatic" in Zephyr which make them automatically registered in the table list. This may be very useful when there are many TSA tables or when the tables are defined in different (often unrelated) libraries linked together. In this case user does not need to build a list of all tables manually.

Driver files The driver source files can be found in a top-level src folder, further divided into the sub-folders:

- ***src/platforms*** platform-specific folder—one folder exists for each supported processor platform (for example; 32-bit Little Endian platform). Each such folder contains a platform header file with data types and a code which implements the potentially platform-specific operations, such as aligned memory access.
- ***src/common*** folder—contains the common driver source files shared by the driver for all supported platforms. All the *.c* files must be added to the project, compiled, and linked together with the application.
  - *freemaster.h* - master driver header file, which declares the common data types, macros, and prototypes of the FreeMASTER driver API functions.
  - *freemaster_cfg.h.example* - this file can serve as an example of the FreeMASTER driver configuration file. Save this file into a project source code folder and rename it to *freemaster_cfg.h*. The FreeMASTER driver code includes this file to get the project-specific configuration options and to optimize the compilation of the driver.

- *freemaster_defcfg.h* - defines the default values for each FreeMASTER configuration option if the option is not set in the *freemaster_cfg.h* file.
- *freemaster_protocol.h* - defines the FreeMASTER protocol constants used internally by the driver.
- *freemaster_protocol.c* - implements the FreeMASTER protocol decoder and handles the basic Get Configuration Value, Memory Read, and Memory Write commands.
- *freemaster_rec.c* - handles the Recorder-specific commands and implements the Recorder sampling and triggering routines. When the Recorder is disabled by the FreeMASTER driver configuration file, this file only compiles to empty API functions.
- *freemaster_scope.c* - handles the Oscilloscope-specific commands. If the Oscilloscope is disabled by the FreeMASTER driver configuration file, this file compiles as void.
- *freemaster_pipes.c* - implements the Pipes functionality when the Pipes feature is enabled.
- *freemaster_appcmd.c* - handles the communication commands used to deliver and execute the Application Commands within the context of the embedded application. When the Application Commands are disabled by the FreeMASTER driver configuration file, this file only compiles to empty API functions.
- *freemaster_tsa.c* - handles the commands specific to the TSA feature. This feature enables the FreeMASTER host tool to obtain the TSA memory descriptors declared in the embedded application. If the TSA is disabled by the FreeMASTER driver configuration file, this file compiles as void.
- *freemaster_tsa.h* - contains the declaration of the macros used to define the TSA memory descriptors. This file is indirectly included into the user application code (via *freemaster.h*).
- *freemaster_sha.c* - implements the SHA-1 hash code used in the password authentication algorithm.
- *freemaster_private.h* - contains the declarations of functions and data types used internally in the driver. It also contains the C pre-processor statements to perform the compile-time verification of the user configuration provided in the *freemaster_cfg.h* file.
- *freemaster_serial.c* - implements the serial protocol logic including the CRC, FIFO queuing, and other communication-related operations. This code calls the functions of the low-level communication driver indirectly via a character-oriented API exported by the specific low-level driver.
- *freemaster_serial.h* - defines the low-level character-oriented Serial API.
- *freemaster_can.c* - implements the CAN protocol logic including the CAN message preparation, signalling using the first data byte in the CAN frame, and other communication-related operations. This code calls the functions of the low-level communication driver indirectly via a message-oriented API exported by the specific low-level driver.
- *freemaster_can.h* - defines the low-level message-oriented CAN API.
- *freemaster_net.c* - implements the Network protocol transport logic including multiple session management code.
- *freemaster_net.h* - definitions related to the Network transport.
- *freemaster_pdbdm.c* - implements the packet-driven BDM communication buffer and other communication-related operations.
- *freemaster_utils.c* - aligned memory copy routines, circular buffer management and other utility functions
- *freemaster_utils.h* - definitions related to utility code.

- ***src/drivers/[sdk]/serial*** - contains the code related to the serial communication implemented using one of the supported SDK frameworks.
  - *freemaster_serial_XXX.c* and *.h* - implement low-level access to the communication peripheral registers. Different files exist for the UART, LPUART, USART, and other kinds of Serial communication modules.
- ***src/drivers/[sdk]/can*** - contains the code related to the serial communication implemented using one of the supported SDK frameworks.
  - *freemaster_XXX.c* and *.h* - implement low-level access to the communication peripheral registers. Different files exist for the FlexCAN, msCAN, MCAN, and other kinds of CAN communication modules.
- ***src/drivers/[sdk]/network*** - contains low-level code adapting the FreeMASTER Network transport to an underlying TCP/IP or RTT stack.
  - *freemaster_net_lwip_tcp.c* and *_udp.c* - default networking implementation of TCP and UDP transports using lwIP stack.
  - *freemaster_net_segger_rtt.c* - implementation of network transport using Segger J-Link RTT interface

Driver configuration The driver is configured using a single header file (*freemaster_cfg.h*). Create this file and save it together with other project source files before compiling the driver code. All FreeMASTER driver source files include the *freemaster_cfg.h* file and use the macros defined here for the conditional and parameterized compilation. The C compiler must locate the configuration file when compiling the driver files. Typically, it can be achieved by putting this file into a folder where the other project-specific included files are stored.

As a starting point to create the configuration file, get the *freemaster_cfg.h.example* file, rename it to *freemaster_cfg.h*, and save it into the project area.

Note: It is NOT recommended to leave the *freemaster_cfg.h* file in the FreeMASTER driver source code folder. The configuration file must be placed at a project-specific location, so that it does not affect the other applications that use the same driver.

Configurable items This section describes the configuration options which can be defined in *freemaster_cfg.h*.

Interrupt modes

```
#define FMSTR_LONG_INTR    [0|1]
#define FMSTR_SHORT_INTR   [0|1]
#define FMSTR_POLL_DRIVEN  [0|1]
```

Value Type

boolean (0 or 1)

Description

Exactly one of the three macros must be defined to non-zero. The others must be defined to zero or left undefined. The non-zero-defined constant selects the interrupt mode of the driver. See *Driver interrupt modes*.

- FMSTR_LONG_INTR — long interrupt mode
- FMSTR_SHORT_INTR — short interrupt mode
- FMSTR_POLL_DRIVEN — poll-driven mode

Note: Some options may not be supported by all communication interfaces. For example, the FMSTR_SHORT_INTR option is not supported by the USB_CDC interface.

Protocol transport

```
#define FMSTR_TRANSPORT [identifier]
```

Value Type

Driver identifiers are structure instance names defined in FreeMASTER source code. Specify one of existing instances to make use of the protocol transport.

Description

Use one of the pre-defined constants, as implemented by the FreeMASTER code. The current driver supports the following transports:

- **FMSTR_SERIAL** - serial communication protocol
- **FMSTR_CAN** - using CAN communication
- **FMSTR_PDBDM** - using packet-driven BDM communication
- **FMSTR_NET** - network communication using TCP or UDP protocol

Serial transport

This section describes configuration parameters used when serial transport is used:

```
#define FMSTR_TRANSPORT FMSTR_SERIAL
```

FMSTR_SERIAL_DRV

Select what low-level driver interface will be used when implementing the Serial communication.

```
#define FMSTR_SERIAL_DRV [identifier]
```

Value Type

Driver identifiers are structure instance names defined in FreeMASTER drivers code. Specify one of existing serial driver instances.

Description

When using MCUXpresso SDK, use one of the following constants (see */drivers/mcuxsdk/serial* implementation):

- **FMSTR_SERIAL_MCUX_UART** - UART driver
- **FMSTR_SERIAL_MCUX_LPUART** - LPUART driver
- **FMSTR_SERIAL_MCUX_USART** - USART driver
- **FMSTR_SERIAL_MCUX_MINIUSART** - miniUSART driver
- **FMSTR_SERIAL_MCUX_QSCI** - DSC QSCI driver
- **FMSTR_SERIAL_MCUX_USB** - USB/CDC class driver (also see code in the */support/mcuxsdk_usb* folder)
- **FMSTR_SERIAL_56F800E_EONCE** - DSC JTAG EOnCE driver

Other SDKs or BSPs may define custom low-level driver interface structure which may be used as FMSTR_SERIAL_DRV. For example:

- **FMSTR_SERIAL_DREG_UART** - demonstrates the low-level interface implemented without the MCUXpresso SDK and using direct access to peripheral registers.

FMSTR_SERIAL_BASE

```
#define FMSTR_SERIAL_BASE [address|symbol]
```

Value Type

Optional address value (numeric or symbolic)

Description

Specify the base address of the UART, LPUART, USART, or other serial peripheral module to be used for the communication. This value is not defined by default. User application should call FMSTR_SetSerialBaseAddress() to select the peripheral module.

FMSTR_COMM_BUFFER_SIZE

```
#define FMSTR_COMM_BUFFER_SIZE [number]
```

Value Type

0 or a value in range 32...255

Description

Specify the size of the communication buffer to be allocated by the driver.
Default value, which suits all driver features, is used when this option is defined as 0.

FMSTR_COMM_RQUEUE_SIZE

```
#define FMSTR_COMM_RQUEUE_SIZE [number]
```

Value Type

Value in range 0...255

Description

Specify the size of the FIFO receiver queue used to quickly receive and store characters in the FMSTR_SHORT_INTR interrupt mode.
The default value is 32 B.

FMSTR_SERIAL_SINGLEWIRE

```
#define FMSTR_SERIAL_SINGLEWIRE [0|1]
```

Value Type

Boolean 0 or 1.

Description

Set to non-zero to enable the “True” single-wire mode which uses a single MCU pin to communicate. The low-level driver enables the pin direction switching when the MCU peripheral supports it.

CAN Bus transport

This section describes configuration parameters used when CAN transport is used:

```
#define FMSTR_TRANSPORT FMSTR_CAN
```

FMSTR_CAN_DRV

Select what low-level driver interface will be used when implementing the CAN communication.

```
#define FMSTR_CAN_DRV [identifier]
```

Value Type

Driver identifiers are structure instance names defined in FreeMASTER drivers code. Specify one of existing CAN driver instances.

Description

When using MCUXpresso SDK, use one of the following constants (see */drivers/mcuxsdk/can implementation*):

- **FMSTR_CAN_MCUX_FLEXCAN** - FlexCAN driver
- **FMSTR_CAN_MCUX_MCAN** - MCAN driver
- **FMSTR_CAN_MCUX_MSCAN** - msCAN driver
- **FMSTR_CAN_MCUX_DSCFLEXCAN** - DSC FlexCAN driver
- **FMSTR_CAN_MCUX_DSCMSCAN** - DSC msCAN driver

Other SDKs or BSPs may define the custom low-level driver interface structure which may be used as FMSTR_CAN_DRV.

FMSTR_CAN_BASE

```
#define FMSTR_CAN_BASE [address|symbol]
```

Value Type

Optional address value (numeric or symbolic)

Description

Specify the base address of the FlexCAN, msCAN, or other CAN peripheral module to be used for the communication. This value is not defined by default. User application should call FMSTR_SetCanBaseAddress() to select the peripheral module.

FMSTR_CAN_CMDID

```
#define FMSTR_CAN_CMDID [number]
```

Value Type

CAN identifier (11-bit or 29-bit number)

Description

CAN message identifier used for FreeMASTER commands (direction from PC Host tool to target application). When declaring 29-bit identifier, combine the numeric value with FMSTR_CAN_EXTID bit. Default value is 0x7AA.

FMSTR_CAN_RSPID

```
#define FMSTR_CAN_RSPID [number]
```

Value Type

CAN identifier (11-bit or 29-bit number)

Description

CAN message identifier used for responding messages (direction from target application to PC Host tool). When declaring 29-bit identifier, combine the numeric value with FMSTR_CAN_EXTID bit. Note that both *CMDID* and *RSPID* values may be the same. Default value is 0x7AA.

FMSTR_FLEXCAN_TXMB

```
#define FMSTR_FLEXCAN_TXMB [number]
```

Value Type

Number in range of 0..N where N is number of CAN message-buffers supported by HW module.

Description

Only used when the FlexCAN low-level driver is used. Define the FlexCAN message buffer for CAN frame transmission. Default value is 0.

FMSTR_FLEXCAN_RXMB

```
#define FMSTR_FLEXCAN_RXMB [number]
```

Value Type

Number in range of 0..N where N is number of CAN message-buffers supported by HW module.

Description

Only used when the FlexCAN low-level driver is used. Define the FlexCAN message buffer for CAN frame reception. Note that the FreeMASTER driver may also operate with a common message buffer used by both TX and RX directions. Default value is 1.

Network transport

This section describes configuration parameters used when Network transport is used:

```
#define FMSTR_TRANSPORT FMSTR_NET
```

FMSTR_NET_DRV

Select network interface implementation.

```
#define FMSTR_NET_DRV [identifier]
```

Value Type

Identifiers are structure instance names defined in FreeMASTER drivers code. Specify one of existing NET driver instances.

Description

When using MCUXpresso SDK, use one of the following constants (see */drivers/mcuxsdk/network implementation*):

- **FMSTR_NET_LWIP_TCP** - TCP communication using lwIP stack
- **FMSTR_NET_LWIP_UDP** - UDP communication using lwIP stack
- **FMSTR_NET_SEGGER_RTT** - Communication using SEGGER J-Link RTT interface

Other SDKs or BSPs may define the custom networking interface which may be used as FMSTR_CAN_DRV.

Add another row below:

FMSTR_NET_PORT

```
#define FMSTR_NET_PORT [number]
```

Value Type

TCP or UDP port number (short integer)

Description

Specifies the server port number used by TCP or UDP protocols.

FMSTR_NET_BLOCKING_TIMEOUT

```
#define FMSTR_NET_BLOCKING_TIMEOUT [number]
```

Value Type

Timeout as number of milliseconds

Description

This value specifies a timeout in milliseconds for which the network socket operations may block the execution inside *FMSTR_Poll*. This may be set high (e.g. 250) when a dedicated RTOS task is used to handle FreeMASTER protocol polling. Set to a lower value when the polling task is also responsible for other operations. Set to 0 to attempt to use non-blocking socket operations.

FMSTR_NET_AUTODISCOVERY

```
#define FMSTR_NET_AUTODISCOVERY [0|1]
```

Value Type

Boolean 0 or 1.

Description

This option enables the FreeMASTER driver to use a separate UDP socket to broadcast auto-discovery messages to network. This helps the FreeMASTER tool to discover the target device address, port and protocol options.

Debugging options

FMSTR_DISABLE

```
#define FMSTR_DISABLE [0|1]
```

Value Type

boolean (0 or 1)

Description

Define as non-zero to disable all FreeMASTER features, exclude the driver code from build, and compile all its API functions empty. This may be useful to remove FreeMASTER without modifying any application source code. Default value is 0 (false).

FMSTR_DEBUG_TX

```
#define FMSTR_DEBUG_TX [0|1]
```

Value Type

Boolean 0 or 1.

Description

Define as non-zero to enable the driver to periodically transmit test frames out on the selected communication interface (SCI or CAN). With the debug transmission enabled, it is simpler to detect problems in the baudrate or other communication configuration settings.

The test frames are transmitted until the first valid command frame is received from the PC Host tool. The test frame is a valid error status frame, as defined by the protocol format. On the serial line, the test frame consists of three printable characters (+©W) which are easy to capture using the serial terminal tools.

This feature requires the FMSTR_Poll() function to be called periodically. Default value is 0 (false).

FMSTR_APPLICATION_STR

```
#define FMSTR_APPLICATION_STR
```

Value Type

String.

Description

Name of the application visible in FreeMASTER host application.

Memory access

FMSTR_USE_READMEM

```
#define FMSTR_USE_READMEM [0|1]
```

Value Type

Boolean 0 or 1.

Description

Define as non-zero to implement the Memory Read command and enable FreeMASTER to have read access to memory and variables. The access can be further restricted by using a TSA feature. Default value is 1 (true).

FMSTR_USE_WRITEMEM

```
#define FMSTR_USE_WRITEMEM [0|1]
```

Value Type

Boolean 0 or 1.

Description

Define as non-zero to implement the Memory Write command.
The default value is 1 (true).

Oscilloscope options

FMSTR_USE_SCOPE

```
#define FMSTR_USE_SCOPE [number]
```

Value Type

Integer number.

Description

Number of Oscilloscope instances to be supported. Set to 0 to disable the Oscilloscope feature. Default value is 0.

FMSTR_MAX_SCOPE_VARS

```
#define FMSTR_MAX_SCOPE_VARS [number]
```

Value Type

Integer number larger than 2.

Description

Number of variables to be supported by each Oscilloscope instance.
Default value is 8.

Recorder options

FMSTR_USE_RECORDER

```
#define FMSTR_USE_RECORDER [number]
```

Value Type

Integer number.

Description

Number of Recorder instances to be supported. Set to 0 to disable the Recorder feature.
Default value is 0.

FMSTR_REC_BUFF_SIZE

```
#define FMSTR_REC_BUFF_SIZE [number]
```

Value Type

Integer number larger than 2.

Description

Defines the size of the memory buffer used by the Recorder instance #0.
Default: not defined, user shall call 'FMSTR_RecorderCreate()" API function to specify this parameter in run time.

FMSTR_REC_TIMEBASE

```
#define FMSTR_REC_TIMEBASE [time specification]
```

Value Type

Number (nanoseconds time).

Description

Defines the base sampling rate in nanoseconds (sampling speed) Recorder instance #0.

Use one of the following macros:

- FMSTR_REC_BASE_SECONDS(x)
- FMSTR_REC_BASE_MILLISEC(x)
- FMSTR_REC_BASE_MICROSEC(x)
- FMSTR_REC_BASE_NANOSEC(x)

Default: not defined, user shall call 'FMSTR_RecorderCreate()" API function to specify this parameter in run time.

FMSTR_REC_FLOAT_TRIG

```
#define FMSTR_REC_FLOAT_TRIG [0|1]
```

Value Type

Boolean 0 or 1.

Description

Define as non-zero to implement the floating-point triggering. Be aware that floating-point triggering may grow the code size by linking the floating-point standard library.

Default value is 0 (false).

Application Commands options

FMSTR_USE_APPCMD

```
#define FMSTR_USE_APPCMD [0|1]
```

Value Type

Boolean 0 or 1.

Description

Define as non-zero to implement the Application Commands feature.
Default value is 0 (false).

FMSTR_APPCMD_BUFF_SIZE

```
#define FMSTR_APPCMD_BUFF_SIZE [size]
```

Value Type

Numeric buffer size in range 1..255

Description

The size of the Application Command data buffer allocated by the driver. The buffer stores the (optional) parameters of the Application Command which waits to be processed.

FMSTR_MAX_APPCMD_CALLS

```
#define FMSTR_MAX_APPCMD_CALLS [number]
```

Value Type

Number in range 0..255

Description

The number of different Application Commands that can be assigned a callback handler function using FMSTR_RegisterAppCmdCall(). Default value is 0.

TSA options

FMSTR_USE_TSA

```
#define FMSTR_USE_TSA [0|1]
```

Value Type

Boolean 0 or 1.

Description

Enable the FreeMASTER TSA feature to be used. With this option enabled, the TSA tables defined in the applications are made available to the FreeMASTER host tool.
Default value is 0 (false).

FMSTR_USE_TSA_SAFETY

```
#define FMSTR_USE_TSA_SAFETY [0|1]
```

Value Type

Boolean 0 or 1.

Description

Enable the memory access validation in the FreeMASTER driver. With this option, the host tool is not able to access the memory which is not described by at least one TSA descriptor. Also a write access is denied for objects defined as read-only in TSA tables.
Default value is 0 (false).

FMSTR_USE_TSA_INROM

```
#define FMSTR_USE_TSA_INROM [0|1]
```

Value Type

Boolean 0 or 1.

Description

Declare all TSA descriptors as *const*, which enables the linker to put the data into the flash memory. The actual result depends on linker settings or the linker commands used in the project.
Default value is 0 (false).

FMSTR_USE_TSA_DYNAMIC

```
#define FMSTR_USE_TSA_DYNAMIC [0|1]
```

Value Type

Boolean 0 or 1.

Description

Enable runtime-defined TSA entries to be added to the TSA table by the FMSTR_SetUpTsaBuff() and FMSTR_TsaAddVar() functions.
Default value is 0 (false).

Pipes options

FMSTR_USE_PIPES

```
#define FMSTR_USE_PIPES [0|1]
```

Value Type

Boolean 0 or 1.

Description

Enable the FreeMASTER Pipes feature to be used.
Default value is 0 (false).

FMSTR_MAX_PIPES_COUNT

```
#define FMSTR_MAX_PIPES_COUNT [number]
```

Value Type

Number in range 1..63.

Description

The number of simultaneous pipe connections to support.
The default value is 1.

Driver interrupt modes To implement the communication, the FreeMASTER driver handles the Serial or CAN module's receive and transmit requests. Use the *freemaster_cfg.h* configuration file to select whether the driver processes the communication automatically in the interrupt service routine handler or if it only polls the status of the module (typically during the application idle time).

This section describes each of the interrupt mode in more details.

Completely Interrupt-Driven operation

Activated using:

```
#define FMSTR_LONG_INTR 1
```

In this mode, both the communication and the FreeMASTER protocol decoding is done in the *FMSTR_SerialIsr*, *FMSTR_CanIsr*, or other interrupt service routine. Because the protocol execution may be a lengthy task (especially with the TSA-Safety enabled) it is recommended to use this mode only if the interrupt prioritization scheme is possible in the application and the FreeMASTER interrupt is assigned to a lower (the lowest) priority.

In this mode, the application code must register its own interrupt handler for all interrupt vectors related to the selected communication interface and call the FMSTR_SerialIsr or FMSTR_CanIsr functions from that handler.

Mixed Interrupt and Polling Modes

Activated using:

```
#define FMSTR_SHORT_INTR 1
```

In this mode, the communication processing time is split between the interrupt routine and the main application loop or task. The raw communication is handled by the *FMSTR_SerialIsr, FMSTR_CanIsr*, or other interrupt service routine, while the protocol decoding and execution is handled by the *FMSTR_Poll* routine. Call *FMSTR_Poll* during the idle time in the application main loop.

The interrupt processing in this mode is relatively fast and deterministic. Upon a serial-receive event, the received character is only placed into a FIFO-like queue and it is not further processed.

Upon a CAN receive event, the received frame is stored into a receive buffer. When transmitting, the characters are fetched from the prepared transmit buffer.

In this mode, the application code must register its own interrupt handler for all interrupt vectors related to the selected communication interface and call the *FMSTR_SerialIsr* or *FMSTR_CanIsr* functions from that handler.

When the serial interface is used as the serial communication interface, ensure that the *FMSTR_Poll* function is called at least once per *N* character time periods. *N* is the length of the FreeMASTER FIFO queue (*FMSTR_COMM_RQUEUE_SIZE*) and the character time is the time needed to transmit or receive a single byte over the SCI line.

Completely Poll-driven

```
#define FMSTR_POLL_DRIVEN 1
```

In this mode, both the communication and the FreeMASTER protocol decoding are done in the *FMSTR_Poll* routine. No interrupts are needed and the *FMSTR_SerialIsr*, *FMSTR_CanIsr*, and similar handlers compile to an empty code.

When using this mode, ensure that the *FMSTR_Poll* function is called by the application at least once per the serial "character time" which is the time needed to transmit or receive a single character.

In the latter two modes (*FMSTR_SHORT_INTR* and *FMSTR_POLL_DRIVEN*), the protocol handling takes place in the FMSTR_Poll routine. An application interrupt can occur in the middle of the Read Memory or Write Memory commands' execution and corrupt the variable being accessed by the FreeMASTER driver. In these two modes, some issues or glitches may occur when using FreeMASTER to visualize or monitor volatile variables modified in interrupt servicing code.

The same issue may appear even in the full interrupt mode (FMSTR_LONG_INTR), if volatile variables are modified in the interrupt code with a priority higher than the priority of the communication interrupt.

Data types Simple portability was one of the main requirements when writing the FreeMASTER driver. This is why the driver code uses the privately-declared data types and the vast majority of the platform-dependent code is separated in the platform-dependent source files. The data types used in the driver API are all defined in the platform-specific header file.

To prevent name conflicts with the symbols used in the application, all data types, macros, and functions have the FMSTR_ prefix. The only global variables used in the driver are the transport and low-level API structures exported from the driver-implementation layer to upper layers. Other than that, all private variables are declared as static and named using the fmstr_ prefix.

Communication interface initialization The FreeMASTER driver does not perform neither the initialization nor the configuration of the peripheral module that it uses to communicate. It is the application startup code responsibility to configure the communication module before the FreeMASTER driver is initialized by the FMSTR_Init call.

When the Serial communication module is used as the FreeMASTER communication interface, configure the UART receive and transmit pins, the serial communication baud rate, parity (no-parity), the character length (eight bits), and the number of stop bits (one) before initializing the FreeMASTER driver. For either the long or the short interrupt modes of the driver (see *Driver interrupt modes*), configure the interrupt controller and register an application-specific interrupt handler for all interrupt sources related to the selected serial peripheral module. Call the FMSTR_SerialIsr function from the application handler.

When a CAN module is used as the FreeMASTER communication interface, configure the CAN receive and transmit pins and the CAN module bit rate before initializing the FreeMASTER driver.

For either the long or the short interrupt modes of the driver (see *Driver interrupt modes*), configure the interrupt controller and register an application-specific interrupt handler for all interrupt sources related to the selected CAN peripheral module. Call the FMSTR_CanIsr function from the application handler.

Note: It is not necessary to enable or unmask the serial nor the CAN interrupts before initializing the FreeMASTER driver. The driver enables or disables the interrupts and communication lines, as required during runtime.

FreeMASTER Recorder calls When using the FreeMASTER Recorder in the application (FMSTR_USE_RECORDER > 0), call the FMSTR_RecorderCreate function early after FMSTR_Init to set up each recorder instance to be used in the application. Then call the FMSTR_Recorder function periodically in the code where the data recording should occur. A typical place to call the Recorder routine is at the timer or PWM interrupts, but it can be anywhere else. The example applications provided together with the driver code call the FMSTR_Recorder in the main application loop.

In applications where FMSTR_Recorder is called periodically with a constant period, specify the period in the Recorder configuration structure before calling FMSTR_RecorderCreate. This setting enables the PC Host FreeMASTER tool to display the X-axis of the Recorder graph properly scaled for the time domain.

Driver usage Start using or evaluating FreeMASTER by opening some of the example applications available in the driver setup package.

Follow these steps to enable the basic FreeMASTER connectivity in the application:

- Make sure that all **.c* files of the FreeMASTER driver from the *src/common/platforms/[your_platform]* folder are a part of the project. See *Driver files* for more details.
- Configure the FreeMASTER driver by creating or editing the *freemaster_cfg.h* file and by saving it into the application project directory. See *Driver configuration* for more details.
- Include the *freemaster.h* file into any application source file that makes the FreeMASTER API calls.
- Initialize the Serial or CAN modules. Set the baud rate, parity, and other parameters of the communication. Do not enable the communication interrupts in the interrupt mask registers.
- For the FMSTR_LONG_INTR and FMSTR_SHORT_INTR modes, install the application-specific interrupt routine and call the FMSTR_SerialIsr or FMSTR_CanIsr functions from this handler.
- Call the FMSTR_Init function early on in the application initialization code.
- Call the FMSTR_RecorderCreate functions for each Recorder instance to enable the Recorder feature.
- In the main application loop, call the FMSTR_Poll API function periodically when the application is idle.
- For the FMSTR_SHORT_INTR and FMSTR_LONG_INTR modes, enable the interrupts globally so that the interrupts can be handled by the CPU.

Communication troubleshooting The most common problem that causes communication issues is a wrong baud rate setting or a wrong pin multiplexer setting of the target MCU. When a communication between the PC Host running FreeMASTER and the target MCU cannot be established, try enabling the FMSTR_DEBUG_TX option in the *freemaster_cfg.h* file and call the FMSTR_Poll function periodically in the main application task loop.

With this feature enabled, the FreeMASTER driver periodically transmits a test frame through the Serial or CAN lines. Use a logic analyzer or an oscilloscope to monitor the signals at the communication pins of the CPU device to examine whether the bit rate and signal polarity are configured properly.

Driver API

This section describes the driver Application Programmers' Interface (API) needed to initialize and use the FreeMASTER serial communication driver.

Control API

There are three key functions to initialize and use the driver.

FMSTR_Init

Prototype

```
FMSTR_BOOL FMSTR_Init(void);
```

- Declaration: *freemaster.h*
- Implementation: *freemaster_protocol.c*

Description

This function initializes the internal variables of the FreeMASTER driver and enables the communication interface. This function does not change the configuration of the selected communication module. The hardware module must be initialized before the *FMSTR_Init* function is called.

A call to this function must occur before calling any other FreeMASTER driver API functions.

FMSTR_Poll

Prototype

```
void FMSTR_Poll(void);
```

- Declaration: *freemaster.h*
- Implementation: *freemaster_protocol.c*

Description

In the poll-driven or short interrupt modes, this function handles the protocol decoding and execution (see *Driver interrupt modes*). In the poll-driven mode, this function also handles the communication interface with the PC. Typically, the *FMSTR_Poll* function is called during the "idle" time in the main application task loop.

To prevent the receive data overflow (loss) on a serial interface, make sure that the FMSTR_Poll function is called at least once per the time calculated as:

*N * Tchar*

where:

- *N* is equal to the length of the receive FIFO queue (configured by the FMSTR_COMM_RQUEUE_SIZE macro). *N* is 1 for the poll-driven mode.
- *Tchar* is the character time, which is the time needed to transmit or receive a single byte over the SCI line.

Note: In the long interrupt mode, this function typically compiles as an empty function and can still be called. It is worthwhile to call this function regardless of the interrupt mode used in the application. This approach enables a convenient switching between the different interrupt modes only by changing the configuration macros in the *freemaster_cfg.h* file.

FMSTR_SerialIsr / FMSTR_CanIsr

Prototype

```
void FMSTR_SerialIsr(void);
void FMSTR_CanIsr(void);
```

- Declaration: *freemaster.h*
- Implementation: *hw-specific low-level driver C file*

Description

This function contains the interrupt-processing code of the FreeMASTER driver. In long or short interrupt modes (see *Driver interrupt modes*), this function must be called from the application interrupt service routine registered for the communication interrupt vector. On platforms where the communication module uses multiple interrupt vectors, the application should register a handler for all vectors and call this function at each interrupt.

Note: In a poll-driven mode, this function is compiled as an empty function and does not have to be used.

Recorder API FMSTR_RecorderCreate

Prototype

```
FMSTR_BOOL FMSTR_RecorderCreate(FMSTR_INDEX recIndex, FMSTR_REC_BUFF* buffCfg);
```

- Declaration: *freemaster.h*
- Implementation: *freemaster_rec.c*

Description

This function registers a recorder instance and enables it to be used by the PC Host tool. Call this function for all recorder instances from 0 to the maximum number defined by the FMSTR_USE_RECORDER configuration option (minus one). An exception to this requirement is the recorder of instance *0* which may be automatically configured by FMSTR_Init when the *freemaster_cfg.h* configuration file defines the *FMSTR_REC_BUFF_SIZE* and *FMSTR_REC_TIMEBASE* options.

For more information, see *Configurable items*.

FMSTR_Recorder

Prototype

```
void FMSTR_Recorder(FMSTR_INDEX recIndex);
```

- Declaration: *freemaster.h*
- Implementation: *freemaster_rec.c*

Description

This function takes a sample of the variables being recorded using the FreeMASTER Recorder instance *recIndex*. If the selected Recorder is not active when the *FMSTR_Recorder* function is being called, the function returns immediately. When the Recorder is active, the values of the variables being recorded are copied into the recorder buffer and the trigger conditions are evaluated.

If a trigger condition is satisfied, the Recorder enters the post-trigger mode, where it counts down the follow-up samples (number of *FMSTR_Recorder* function calls) and de-activates the Recorder when the required post-trigger samples are finished.

The *FMSTR_Recorder* function is typically called in the timer or PWM interrupt service routines. This function can also be called in the application main loop (for testing purposes).

FMSTR_RecorderTrigger

Prototype

```
void FMSTR_RecorderTrigger(FMSTR_INDEX recIndex);
```

- Declaration: *freemaster.h*
- Implementation: *freemaster_rec.c*

Description

This function forces the Recorder trigger condition to happen, which causes the Recorder to be automatically deactivated after the post-trigger samples are sampled. Use this function in the application code for programmatic control over the Recorder triggering. This can be useful when a more complex triggering conditions need to be used.

Fast Recorder API The Fast Recorder feature is not available in the FreeMASTER driver version 3. This feature was heavily dependent on the target platform and it was only available for the 56F8xxxx DSCs.

TSA Tables When the TSA is enabled in the FreeMASTER driver configuration file (by setting the FMSTR_USE_TSA macro to a non-zero value), it defines the so-called TSA tables in the application. This section describes the macros that must to be used to define the TSA tables.

There can be any number of TSA tables spread across the application source files. There must be always exactly one TSA Table List defined, which informs the FreeMASTER driver about the active TSA tables.

When there is at least one TSA table and one TSA Table List defined in the application, the TSA information automatically appears in the FreeMASTER symbols list. The symbols can then be used to create FreeMASTER variables for visualization or control.

TSA table definition

The TSA table describes the static or global variables together with their address, size, type, and access-protection information. If the TSA-described variables are of a structure type, the TSA table may also describe this type and provide an access to the individual structure members of the variable.

The TSA table definition begins with the FMSTR_TSA_TABLE_BEGIN macro with a *table_id* identifying the table. The *table_id* shall be a valid C-langiage symbol.

```
FMSTR_TSA_TABLE_BEGIN(table_id)
```

After this opening macro, the TSA descriptors are placed using these macros:

```
/* Adding variable descriptors */
FMSTR_TSA_RW_VAR(name, type)  /* read/write variable entry */
FMSTR_TSA_RO_VAR(name, type)  /* read-only variable entry */

/* Description of complex data types */
FMSTR_TSA_STRUCT(struct_name) /* structure or union type entry */
FMSTR_TSA_MEMBER(struct_name, member_name, type)  /* structure member entry */

/* Memory blocks */
FMSTR_TSA_RW_MEM(name, type, address, size) /* read/write memory block */
FMSTR_TSA_RO_MEM(name, type, address, size) /* read-only memory block */
```

The table is closed using the FMSTR_TSA_TABLE_END macro:

```
FMSTR_TSA_TABLE_END()
```

TSA descriptor parameters

The TSA descriptor macros accept these parameters:

- *name* — variable name. The variable must be defined before the TSA descriptor references it.
- *type* — variable or member type. Only one of the pre-defined type constants may be used (see below).
- *struct_name* — structure type name. The type must be defined (typedef) before the TSA descriptor references it.
- *member_name* — structure member name.

Note: The structure member descriptors (FMSTR_TSA_MEMBER) must immediately follow the parent structure descriptor (FMSTR_TSA_STRUCT) in the table.

Note: To write-protect the variables in the FreeMASTER driver (FMSTR_TSA_RO_VAR), enable the TSA-Safety feature in the configuration file.

TSA variable types

The table lists *type* identifiers which can be used in TSA descriptors:

Constant	Description
FMSTR_TSA_UINT*n*	Unsigned integer type of size *n* bits (n=8,16,32,64)
FMSTR_TSA_SINT*n*	Signed integer type of size *n* bits (n=8,16,32,64)
FMSTR_TSA_FRAC*n*	Fractional number of size *n* bits (n=16,32,64).
FMSTR_TSA_FRAC_Q(*m*,*n*)	Signed fractional number in general Q form (m+n+1 total bits)
FMSTR_TSA_FRAC_UQ(*m*,*n*)	Unsigned fractional number in general UQ form (m+n total bits)
FMSTR_TSA_FLOAT	4-byte standard IEEE floating-point type
FMSTR_TSA_DOUBLE	8-byte standard IEEE floating-point type
FMSTR_TSA_POINTER	Generic pointer type defined (platform-specific 16 or 32 bit)
FMSTR_TSA_USERTYPE(*name*)	Structure or union type declared with FMSTR_TSA_STRUCT record

TSA table list

There shall be exactly one TSA Table List in the application. The list contains one entry for each TSA table defined anywhere in the application.

The TSA Table List begins with the FMSTR_TSA_TABLE_LIST_BEGIN macro and continues with the TSA table entries for each table.

```
FMSTR_TSA_TABLE_LIST_BEGIN()

FMSTR_TSA_TABLE(table_id)
FMSTR_TSA_TABLE(table_id2)
FMSTR_TSA_TABLE(table_id3)
...
```

The list is closed with the FMSTR_TSA_TABLE_LIST_END macro:

```
FMSTR_TSA_TABLE_LIST_END()
```

TSA Active Content entries

FreeMASTER v2.0 and higher supports TSA Active Content, enabling the TSA tables to describe the memory-mapped files, virtual directories, and URL hyperlinks. FreeMASTER can access such objects similarly to accessing the files and folders on the local hard drive.

With this set of TSA entries, the FreeMASTER pages can be embedded directly into the target MCU flash and accessed by FreeMASTER directly over the communication line. The HTML-coded pages rendered inside the FreeMASTER window can access the TSA Active Content resources using a special URL referencing the *fmstr:* protocol.

This example provides an overview of the supported TSA Active Content entries:

```
FMSTR_TSA_TABLE_BEGIN(files_and_links)

/* Directory entry applies to all subsequent MEMFILE entries */
FMSTR_TSA_DIRECTORY("/text_files")     /* entering a new virtual directory */

/* The readme.txt file will be accessible at the fmstr://text_files/readme.txt URL */
FMSTR_TSA_MEMFILE("readme.txt", readme_txt, sizeof(readme_txt)) /* memory-mapped file */

/* Files can also be specified with a full path so the DIRECTORY entry does not apply */
FMSTR_TSA_MEMFILE("/index.htm", index, sizeof(index))          /* memory-mapped file */
FMSTR_TSA_MEMFILE("/prj/demo.pmp", demo_pmp, sizeof(demo_pmp)) /* memory-mapped file */

/* Hyperlinks can point to a local MEMFILE object or to the Internet */
FMSTR_TSA_HREF("Board's Built-in Welcome Page", "/index.htm")
FMSTR_TSA_HREF("FreeMASTER Home Page", "http://www.nxp.com/freemaster")

/* Project file links simplify opening the projects from any URLs */
FMSTR_TSA_PROJECT("Demonstration Project (embedded)", "/prj/demo.pmp")
FMSTR_TSA_PROJECT("Full Project (online)", "http://mycompany.com/prj/demo.pmp")

FMSTR_TSA_TABLE_END()
```

TSA API FMSTR_SetUpTsaBuff

Prototype

```
FMSTR_BOOL FMSTR_SetUpTsaBuff(FMSTR_ADDR buffAddr, FMSTR_SIZE buffSize);
```

- Declaration: *freemaster.h*
- Implementation: *freemaster_tsa.c*

Arguments

- *buffAddr* [in] - address of the memory buffer for the dynamic TSA table
- *buffSize* [in] - size of the memory buffer which determines the maximum number of TSA entries to be added in the runtime

Description

This function must be used to assign the RAM memory buffer to the TSA subsystem when FMSTR_USE_TSA_DYNAMIC is enabled. The memory buffer is then used to store the TSA entries added dynamically to the runtime TSA table using the FMSTR_TsaAddVar function call. The runtime TSA table is processed by the FreeMASTER PC Host tool along with all static tables as soon as the communication port is open.

The size of the memory buffer determines the number of TSA entries that can be added dynamically. Depending on the MCU platform, one TSA entry takes either 8 or 16 bytes.

FMSTR_TsaAddVar

Prototype

```
FMSTR_BOOL FMSTR_TsaAddVar(FMSTR_TSATBL_STRPTR tsaName, FMSTR_TSATBL_STRPTR
↪tsaType,
    FMSTR_TSATBL_VOIDPTR varAddr, FMSTR_SIZE32 varSize,
    FMSTR_SIZE flags);
```

- Declaration: *freemaster.h*
- Implementation: *freemaster_tsa.c*

Arguments

- *tsaName* [in] - name of the object
- *tsaType* [in] - name of the object type
- *varAddr* [in] - address of the object
- *varSize* [in] - size of the object
- *flags* [in] - access flags; a combination of these values:
  - *FMSTR_TSA_INFO_RO_VAR* — read-only memory-mapped object (typically a variable)
  - *FMSTR_TSA_INFO_RW_VAR* — read/write memory-mapped object
  - *FMSTR_TSA_INFO_NON_VAR* — other entry, describing structure types, structure members, enumerations, and other types

Description

This function can be called only when the dynamic TSA table is enabled by the FMSTR_USE_TSA_DYNAMIC configuration option and when the FMSTR_SetUpTsaBuff function call is made to assign the dynamic TSA table memory. This function adds an entry into the dynamic TSA table. It can be used to register a read-only or read/write memory object or describe an item of the user-defined type.

See *TSA table definition* for more details about the TSA table entries.

Application Commands API FMSTR_GetAppCmd

Prototype

```
FMSTR_APPCMD_CODE FMSTR_GetAppCmd(void);
```

- Declaration: *freemaster.h*
- Implementation: *freemaster_appcmd.c*

Description

This function can be used to detect if there is an Application Command waiting to be processed by the application. If no command is pending, this function returns the FMSTR_APPCMDRESULT_NOCMD constant. Otherwise, this function returns the code of the Application Command that must be processed. Use the FMSTR_AppCmdAck call to acknowledge the Application Command after it is processed and to return the appropriate result code to the host.

The FMSTR_GetAppCmd function does not report the commands for which a callback handler function exists. If the FMSTR_GetAppCmd function is called when a callback-registered command is pending (and before it is actually processed by the callback function), this function returns FMSTR_APPCMDRESULT_NOCMD.

FMSTR_GetAppCmdData

Prototype

```
FMSTR_APPCMD_PDATA FMSTR_GetAppCmdData(FMSTR_SIZE* dataLen);
```

- Declaration: *freemaster.h*
- Implementation: *freemaster_appcmd.c*

Arguments

- *dataLen* [out] - pointer to the variable that receives the length of the data available in the buffer. It can be NULL when this information is not needed.

Description

This function can be used to retrieve the Application Command data when the application determines that an Application Command is pending (see *FMSTR_GetAppCmd*).

There is just a single buffer to hold the Application Command data (the buffer length is FMSTR_APPCMD_BUFF_SIZE bytes). If the data are to be used in the application after the command is processed by the FMSTR_AppCmdAck call, copy the data out to a private buffer.

FMSTR_AppCmdAck

Prototype

```
void FMSTR_AppCmdAck(FMSTR_APPCMD_RESULT resultCode);
```

- Declaration: *freemaster.h*
- Implementation: *freemaster_appcmd.c*

Arguments

- *resultCode* [in] - the result code which is to be returned to FreeMASTER

Description

This function is used when the Application Command processing finishes in the application. The resultCode passed to this function is returned back to the host and the driver is re-initialized to expect the next Application Command.

After this function is called and before the next Application Command arrives, the return value of the FMSTR_GetAppCmd function is FMSTR_APPCMDRESULT_NOCMD.

FMSTR_AppCmdSetResponseData

Prototype

```
void FMSTR_AppCmdSetResponseData(FMSTR_ADDR resultDataAddr, FMSTR_SIZE resultDataLen);
```

- Declaration: *freemaster.h*
- Implementation: *freemaster_appcmd.c*

Arguments

- *resultDataAddr* [in] - pointer to the data buffer that is to be copied to the Application Command data buffer
- *resultDataLen* [in] - length of the data to be copied. It must not exceed the FMSTR_APPCMD_BUFF_SIZE value.

Description

This function can be used before the Application Command processing finishes, when there are data to be returned back to the PC.

The response data buffer is copied into the Application Command data buffer, from where it is accessed when the host requires it. Do not use FMSTR_GetAppCmdData and the data buffer after FMSTR_AppCmdSetResponseData is called.

Note: The current version of FreeMASTER does not support the Application Command response data.

FMSTR_RegisterAppCmdCall

Prototype

```
FMSTR_BOOL FMSTR_RegisterAppCmdCall(FMSTR_APPCMD_CODE appCmdCode, FMSTR_
↪PAPPCMDFUNC callbackFunc);
```

- Declaration: *freemaster.h*
- Implementation: *freemaster_appcmd.c*

Arguments

- *appCmdCode* [in] - the Application Command code for which the callback is to be registered
- *callbackFunc* [in] - pointer to the callback function that is to be registered. Use NULL to unregister a callback registered previously with this Application Command.

Return value

This function returns a non-zero value when the callback function was successfully registered or unregistered. It can return zero when trying to register a callback function for more than FMSTR_MAX_APPCMD_CALLS different Application Commands.

Description

This function can be used to register the given function as a callback handler for the Application Command. The Application Command is identified using single-byte code. The callback function is invoked automatically by the FreeMASTER driver when the protocol decoder obtains a request to get the application command result code.

The prototype of the callback function is

```
FMSTR_APPCMD_RESULT HandlerFunction(FMSTR_APPCMD_CODE nAppcmd,
    FMSTR_APPCMD_PDATA pData, FMSTR_SIZE nDataLen);
```

Where:

- *nAppcmd* -Application Command code
- *pData* —points to the Application Command data received (if any)
- *nDataLen* —information about the Application Command data length

The return value of the callback function is used as the Application Command Result Code and returned to FreeMASTER.

Note: The FMSTR_MAX_APPCMD_CALLS configuration macro defines how many different Application Commands may be handled by a callback function. When FMSTR_MAX_APPCMD_CALLS is undefined or defined as zero, the FMSTR_RegisterAppCmdCall function always fails.

Pipes API FMSTR_PipeOpen

Prototype

```
FMSTR_HPIPE FMSTR_PipeOpen(FMSTR_PIPE_PORT pipePort, FMSTR_PPIPEFUNC pipeCallback,
↪
    FMSTR_ADDR pipeRxBuff, FMSTR_PIPE_SIZE pipeRxSize,
    FMSTR_ADDR pipeTxBuff, FMSTR_PIPE_SIZE pipeTxSize,
    FMSTR_U8 type, const FMSTR_CHAR *name);
```

- Declaration: *freemaster.h*
- Implementation: *freemaster_pipes.c*

Arguments

- *pipePort* [in] - port number that identifies the pipe for the client
- *pipeCallback* [in] - pointer to the callback function that is called whenever a pipe data status changes
- *pipeRxBuff* [in] - address of the receive memory buffer
- *pipeRxSize* [in] - size of the receive memory buffer
- *pipeTxBuff* [in] - address of the transmit memory buffer
- *pipeTxSize* [in] - size of the transmit memory buffer
- *type* [in] - a combination of FMSTR_PIPE_MODE_xxx and FMSTR_PIPE_SIZE_xxx constants describing primary pipe data format and usage. This type helps FreeMASTER decide how to access the pipe by default. Optional, use 0 when undetermined.
- *name* [in] - user name of the pipe port. This name is visible to the FreeMASTER user when creating the graphical pipe interface.

Description

This function initializes a new pipe and makes it ready to accept or send the data to the PC Host client. The receive memory buffer is used to store the received data before they are read out by the FMSTR_PipeRead call. When this buffer gets full, the PC Host client denies the data transmission into this pipe until there is enough free space again. The transmit memory buffer is used to store the data transmitted by the application to the PC Host client using the FMSTR_PipeWrite call. The transmit buffer can get full when the PC Host is disconnected or when it is slow in receiving and reading out the pipe data.

The function returns the pipe handle which must be stored and used in the subsequent calls to manage the pipe object.

The callback function (if specified) is called whenever new data are received through the pipe and available for reading. This callback is also called when the data waiting in the transmit buffer are successfully pushed to the PC Host and the transmit buffer free space increases. The prototype of the callback function provided by the user application must be as follows. The *PipeHandler* name is only a placeholder and must be defined by the application.

```
void PipeHandler(FMSTR_HPIPE pipeHandle);
```

FMSTR_PipeClose

Prototype

```
void FMSTR_PipeClose(FMSTR_HPIPE pipeHandle);
```

- Declaration: *freemaster.h*
- Implementation: *freemaster_pipes.c*

Arguments

- *pipeHandle* [in] - pipe handle returned from the FMSTR_PipeOpen function call

Description

This function de-initializes the pipe object. No data can be received or sent on the pipe after this call.

FMSTR_PipeWrite

Prototype

```
FMSTR_PIPE_SIZE FMSTR_PipeWrite(FMSTR_HPIPE pipeHandle, FMSTR_ADDR pipeData,
    FMSTR_PIPE_SIZE pipeDataLen, FMSTR_PIPE_SIZE writeGranularity);
```

- Declaration: *freemaster.h*
- Implementation: *freemaster_pipes.c*

Arguments

- *pipeHandle* [in] - pipe handle returned from the FMSTR_PipeOpen function call
- *pipeData* [in] - address of the data to be written
- *pipeDataLen* [in] - length of the data to be written
- *writeGranularity* [in] - size of the minimum unit of data which is to be written

Description

This function puts the user-specified data into the pipe's transmit memory buffer and schedules it for transmission. This function returns the number of bytes that were successfully written into the buffer. This number may be smaller than the number of the requested bytes if there is not enough free space in the transmit buffer.

The *writeGranularity* argument can be used to split the data into smaller chunks, each of the size given by the *writeGranularity* value. The FMSTR_PipeWrite function writes as many data chunks as possible into the transmit buffer and does not attempt to write an incomplete chunk. This feature can prove to be useful to avoid the intermediate caching when writing an array of integer values or other multi-byte data items. When making the nGranularity value equal to the nLength value, all data are considered as one chunk which is either written successfully as a whole or not at all. The nGranularity value of 0 or 1 disables the data-chunk approach.

FMSTR_PipeRead

Prototype

```
FMSTR_PIPE_SIZE FMSTR_PipeRead(FMSTR_HPIPE pipeHandle, FMSTR_ADDR pipeData,
    FMSTR_PIPE_SIZE pipeDataLen, FMSTR_PIPE_SIZE readGranularity);
```

- Declaration: *freemaster.h*
- Implementation: *freemaster_pipes.c*

Arguments

- *pipeHandle* [in] - pipe handle returned from the FMSTR_PipeOpen function call
- *pipeData* [in] - address of the data buffer to be filled with the received data
- *pipeDataLen* [in] - length of the data to be read
- *readGranularity* [in] - size of the minimum unit of data which is to be read

Description

This function copies the data received from the pipe from its receive buffer to the user buffer for further processing. The function returns the number of bytes that were successfully copied to the buffer. This number may be smaller than the number of the requested bytes if there is not enough data bytes available in the receive buffer.

The readGranularity argument can be used to copy the data in larger chunks in the same way as described in the FMSTR_PipeWrite function.

API data types This section describes the data types used in the FreeMASTER driver. The information provided here can be useful when modifying or porting the FreeMASTER Communication Driver to new NXP platforms.

Note: The licensing conditions prohibit use of FreeMASTER and the FreeMASTER Communication Driver with non-NXP MPU or MCU products.

Public common types

The table below describes the public data types used in the FreeMASTER driver API calls. The data types are declared in the *freemaster.h* header file.

Type name	Description
FMSTR_ADDR	Data type used to hold the memory address. On most platforms, this is normally a C-pointer, but it may also be a pure integer type.
For example, this type is defined as long integer on the 56F8xxx platform where the 24-bit addresses must be supported, but the C-pointer may be only 16 bits wide in some compiler configurations.	
FMSTR_SIZE	Data type used to hold the memory block size.
It is required that this type is unsigned and at least 16 bits wide integer.	
FMSTR_BOOL	Data type used as a general boolean type.
This type is used only in zero/non-zero conditions in the driver code.	
FMSTR_APPCM	Data type used to hold the Application Command code.
Generally, this is an unsigned 8-bit value.	
FMSTR_APPCM	Data type used to create the Application Command data buffer.
Generally, this is an unsigned 8-bit value.	
FMSTR_APPCM	Data type used to hold the Application Command result code.
Generally, this is an unsigned 8-bit value.	

Public TSA types

The table describes the TSA-specific public data types. These types are declared in the *freemaster_tsa.h* header file, which is included in the user application indirectly by the *freemaster.h* file.

FMSTR_TSA_TII	Data type used to hold a descriptor index in the TSA table or a table index in the list of TSA tables.
By default, this is defined as FMSTR_SIZE.	
FMSTR_TSA_TS	Data type used to hold a memory block size, as used in the TSA descriptors.
By default, this is defined as FMSTR_SIZE.	

Public Pipes types

The table describes the data types used by the FreeMASTER Pipes API:

FMSTR_HPIPE	Pipe handle that identifies the open-pipe object.
Generally, this is a pointer to a void type.	
FMSTR_PIPE_P(	Integer type required to hold at least 7 bits of data.
Generally, this is an unsigned 8-bit or 16-bit type.	
FMSTR_PIPE_SI	Integer type required to hold at least 16 bits of data.
This is used to store the data buffer sizes.	
FMSTR_PPIPEF	Pointer to the pipe handler function.
See *FMSTR_PipeOpen* for more details.	

Internal types

The table describes the data types used internally by the FreeMASTER driver. The data types are declared in the platform-specific header file and they are not available in the application code.

FMSTR_U8	The smallest memory entity. On the vast majority of platforms, this is an unsigned 8-bit integer. On the 56F8xx DSP platform, this is defined as an unsigned 16-bit integer.
FMSTR_U16	Unsigned 16-bit integer.
FMSTR_U32	Unsigned 32-bit integer.
FMSTR_S8	Signed 8-bit integer.
FMSTR_S16	Signed 16-bit integer.
FMSTR_S32	Signed 32-bit integer.
FMSTR_FLOAT	4-byte standard IEEE floating-point type.
FMSTR_FLAGS	Data type forming a union with a structure of flag bit-fields.
FMSTR_SIZE8	Data type holding a general size value, at least 8 bits wide.
FMSTR_INDEX	General for-loop index. Must be signed, at least 16 bits wide.
FMSTR_BCHR	A single character in the communication buffer. Typically, this is an 8-bit unsigned integer, except for the DSP platforms where it is a 16-bit integer.
FMSTR_BPTR	A pointer to the communication buffer (an array of FMSTR_BCHR).

Revision history This Table summarizes the changes done to this document since the initial release.

Revision	Date	Description
1.0	03/2006	Limited initial release
2.0	09/2007	Updated for FreeMASTER version. New Freescale document template used.
2.1	12/2007	Added description of the new Fast Recorder feature and its API.
2.2	04/2010	Added support for MPC56xx platform, Added new API for use CAN interface.
2.3	04/2011	Added support for Kxx Kinetis platform and MQX operating system.
2.4	06/2011	Serial driver update, adds support for USB CDC interface.
2.5	08/2011	Added Packet Driven BDM interface.
2.7	12/2013	Added FLEXCAN32 interface, byte access and isr callback configuration option.
2.8	06/2014	Removed obsolete license text, see the software package content for up-to-date license.
2.9	03/2015	Update for driver version 1.8.2 and 1.9: FreeMASTER Pipes, TSA Active Content, LIN Transport Layer support, DEBUG-TX communication troubleshooting, Kinetis SDK support.
3.0	08/2016	Update for driver version 2.0: Added support for MPC56xx, MPC57xx, KEAxx and S32Kxx platforms. New NXP document template as well as new license agreement used. added MCAN interface. Folders structure at the installation destination was rearranged.
4.0	04/2019	Update for driver released as part of FreeMASTER v3.0 and MCUXpresso SDK 2.6. Updated to match new V4 serial communication protocol and new configuration options. This version of the document removes substantial portion of outdated information related to S08, S12, ColdFire, Power and other legacy platforms.
4.1	04/2020	Minor update for FreeMASTER driver included in MCUXpresso SDK 2.8.
4.2	09/2020	Added example applications description and information about the MCUXpresso Config Tools. Fixed the pipe-related API description.
4.3	10/2024	Added description of Network and Segger J-Link RTT interface configuration. Accompanying the MCUXpresso SDK version 24.12.00.
4.4	04/2025	Added Zephyr-specific information. Accompanying the MCUXpresso SDK version 25.06.00.

3.3 Multicore SDK

Multicore Software Development Kit (MCSDK) provides comprehensive software support for NXP multicore devices. The MCSDK is combined with the MCUXpresso SDK to form a framework for easy development of multicore applications.

3.3.1 Quick links

- *Release Notes*

- *Multicore SDK Changelog*

3.3.2 Components

Component	Description
RPMSG-Lite	Lightweight implementation of the Remote Processor Messaging (RPMsg) protocol for inter-core messaging.
Multicore Manager	Services for multicore systems (core start/stop, events, and monitoring).
eRPC	Embedded RPC system suitable for multicore and multiprocessor designs.

MCSDK Release Notes

Multicore SDK (MCSDK) Release Notes Overview

These are the release notes for the NXP **Multicore Software Development Kit (MCSDK)**.

Item	Value
MCSDK version	**26.09.00**
Scope	Multicore middleware components and examples
Location in MCUXpresso SDK	<MCUXpressoSDK_install_dir>/middleware/multicore/

The MCSDK is combined with the MCUXpresso SDK to provide a framework for developing multicore applications on NXP devices.

What's new

Component updates

Review detailed changes per component:

- eRPC: *CHANGELOG*
- RPMSG-Lite: *CHANGELOG*
- Multicore Manager (MCMGR): *CHANGELOG*

Supported evaluation boards

Boards with enabled multicore example coverage in this release:

Multicore examples
LPCXpresso55S69FRDM-K32L3A6MIMXRT1170-EVKBMIMXRT1160-EVKMIMXRT1180-EVKMCX-N5XX-EVKMCX-N9XX-EVKFRDM-MCXN947MIMXRT700-EVKKW47-EVKKW47-LOCFRDM-MCXW72MCX-W72-EVKFRDM-IMXRT1186

Development tools

The MCSDK is compiled and tested with the toolchains described in the MCUXpresso SDK documentation:

- https://mcuxpresso.nxp.com/mcuxsdk/latest/html/gsd/installation.html#toolchain

Release contents

This table describes the release contents. Not all MCUXpresso SDK packages contain the full set of these components.

Deliverable	Location
Multicore SDK location (<MCSDK_dir>)	<MCUXpressoSDK_install_dir>/middleware/multicore/
Documentation	<MCSDK_dir>/mcuxsdk-doc/
Embedded Remote Procedure Call (eRPC)	<MCSDK_dir>/erpc/
Multicore Manager (MCMGR)	<MCSDK_dir>/mcmgr/
RPMSG-Lite	<MCSDK_dir>/rpmsg-lite/
Multicore demo applications	<MCUXpressoSDK_install_dir>/examples/multicore_examples/

MCSDK component overview

Together, the MCSDK and the MCUXpresso SDK form a framework for developing software for NXP multicore devices. The MCSDK release includes:

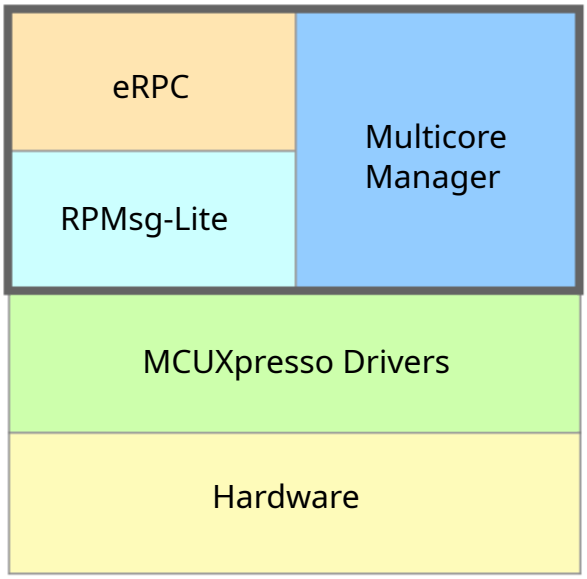
- Embedded Remote Procedure Call (eRPC)
- Multicore Manager (MCMGR)
- Remote Processor Messaging – Lite (RPMSG-Lite)

The MCSDK also includes documentation and demo applications for multicore communication.

Demo applications

The demo applications demonstrate MCSDK component usage on supported development boards.

Examples are located under:



- Multicore: <MCUXpressoSDK_install_dir>/examples/multicore_examples/

MCSDK Getting Started

Getting Started with Multicore SDK (MCSDK) Overview

The **Multicore Software Development Kit (MCSDK)** provides software components for NXP dual/multicore devices. The MCSDK is combined with the MCUXpresso SDK to provide a framework for developing multicore applications.

All MCSDK-related files are located in:

- <MCUXpressoSDK_install_dir>/middleware/multicore/

For supported toolchain versions, see the release notes.

- *MCSDK Changelog*
- Component repositories (within MCSDK):
  - RPMSG-Lite
  - Multicore Manager (MCMGR)
  - eRPC
- eRPC detailed Getting Started guide:

  - eRPC Getting Started

MCSDK components

The MCSDK consists of the following components:

- **Embedded Remote Procedure Call (eRPC):** Library + code generator implementing transparent function calls to services running on another core.
- **Multicore Manager (MCMGR):** Core management services (start/stop secondary cores, events, monitoring).
- **Remote Processor Messaging – Lite (RPMSG-Lite):** Lightweight inter-processor messaging library based on RPMsg.

Where things live

Item	Path
MCSDK root	<MCUXpressoSDK_install_dir>/middleware/multicore/
eRPC	<MCUXpressoSDK_install_dir>/middleware/multicore/erpc/
MCMGR	<MCUXpressoSDK_install_dir>/middleware/multicore/mcmgr/
RPMSG-Lite	<MCUXpressoSDK_install_dir>/middleware/multicore/rpmsg-lite/
MCSDK documentation	<MCUXpressoSDK_install_dir>/middleware/multicore/mcuxsdk-doc/
Multicore examples	<MCUXpressoSDK_install_dir>/examples/multicore_examples/

MCSDK demo applications

Multicore example applications are stored together with other MCUXpresso SDK examples.

Location	Folder
Multicore example projects	<MCUXpressoSDK_install_dir>/examples/multicore_examples/<application_name>/

Each example application contains a README describing setup, required images, and runtime behavior.

Inter-Processor Communication (IPC) levels

The MCSDK provides several mechanisms for Inter-Processor Communication (IPC). Pick the lightest one that matches your requirements.

IPC using low-level drivers

NXP multicore SoCs commonly provide dedicated IPC peripherals (Mailbox for some LPC parts, Messaging Unit (MU) for some Kinetis and i.MX parts).

This is the most lightweight approach: using the Mailbox/MU driver API functions, it is possible to pass a value from core to core via registers (scalar or pointer to shared memory) and trigger inter-core interrupts for notifications.

For details about individual driver API functions, see the MCUXpresso SDK API Reference Manual of the specific device.

Messaging mechanism (RPMSG-Lite)

On top of Mailbox/MU drivers, a messaging system can be implemented, allowing messages to be sent between endpoints created on each CPU.

RPMSG-Lite provides this capability and is the preferred MCUXpresso SDK messaging library. It implements ring buffers in shared memory for message exchange.

This costs additional code and data memory, but provides a unified messaging API and helps portability across devices/RTOSes.

Remote procedure calls (eRPC)

To facilitate IPC further, eRPC allows remote function invocation via a simple local function call.

Using different transport layers, it can communicate:

- between individual cores of multicore SoCs (commonly via RPMSG-Lite)
- between separate processors (SPI, UART, TCP/IP)

If the communicating peer is a Linux user-space application, the generated code can be in C/C++ or Python.

The IPC levels demonstrate the scalability of the MCSDK. Based on application needs, different IPC techniques can be used depending on complexity, speed, memory, and system design.

Changelog Multicore SDK

All notable changes to this project will be documented in this file.

The format is based on Keep a Changelog, and this project adheres to Semantic Versioning.

[26.09.00]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.14.0
  - eRPC generator (erpcgen) v1.14.0
  - Multicore Manager (MCMgr) v5.3.0
  - RPMsg-Lite v5.5.0

[26.06.00]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.14.0
  - eRPC generator (erpcgen) v1.14.0

  - Multicore Manager (MCMgr) v5.2.0
  - RPMsg-Lite v5.4.1

[26.03.00]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.14.0
  - eRPC generator (erpcgen) v1.14.0
  - Multicore Manager (MCMgr) v5.1.0
  - RPMsg-Lite v5.4.0

[25.12.00]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.14.0
  - eRPC generator (erpcgen) v1.14.0
  - Multicore Manager (MCMgr) v5.0.2
  - RPMsg-Lite v5.3.0

[25.09.00]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.14.0
  - eRPC generator (erpcgen) v1.14.0
  - Multicore Manager (MCMgr) v5.0.1
  - RPMsg-Lite v5.2.1

[25.06.00]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.14.0
  - eRPC generator (erpcgen) v1.14.0
  - Multicore Manager (MCMgr) v5.0.0
  - RPMsg-Lite v5.2.0

[25.03.00]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.13.0
  - eRPC generator (erpcgen) v1.13.0
  - Multicore Manager (MCMgr) v4.1.7
  - RPMsg-Lite v5.1.4

[24.12.00]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.13.0
  - eRPC generator (erpcgen) v1.13.0
  - Multicore Manager (MCMgr) v4.1.6
  - RPMsg-Lite v5.1.3

[2.16.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.13.0
  - eRPC generator (erpcgen) v1.13.0
  - Multicore Manager (MCMgr) v4.1.5
  - RPMsg-Lite v5.1.2

[2.15.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.12.0
  - eRPC generator (erpcgen) v1.12.0
  - Multicore Manager (MCMgr) v4.1.5
  - RPMsg-Lite v5.1.1

[2.14.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.11.0
  - eRPC generator (erpcgen) v1.11.0
  - Multicore Manager (MCMgr) v4.1.4
  - RPMsg-Lite v5.1.0

[2.13.0_imxrt1180a0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.10.0
  - eRPC generator (erpcgen) v1.10.0
  - Multicore Manager (MCMgr) v4.1.3
  - RPMsg-Lite v5.0.0

[2.13.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.10.0
  - eRPC generator (erpcgen) v1.10.0
  - Multicore Manager (MCMgr) v4.1.3
  - RPMsg-Lite v5.0.0

[2.12.0_imx93]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.9.1
  - eRPC generator (erpcgen) v1.9.1
  - Multicore Manager (MCMgr) v4.1.2
  - RPMsg-Lite v4.0.1

[2.12.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.9.1
  - eRPC generator (erpcgen) v1.9.1
  - Multicore Manager (MCMgr) v4.1.2
  - RPMsg-Lite v4.0.0

[2.11.1]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.9.0
  - eRPC generator (erpcgen) v1.9.0
  - Multicore Manager (MCMgr) v4.1.1
  - RPMsg-Lite v3.2.1

[2.11.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.9.0
  - eRPC generator (erpcgen) v1.9.0
  - Multicore Manager (MCMgr) v4.1.1
  - RPMsg-Lite v3.2.0

[2.10.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.8.1
  - eRPC generator (erpcgen) v1.8.1
  - Multicore Manager (MCMgr) v4.1.1
  - RPMsg-Lite v3.1.2

[2.9.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.8.0
  - eRPC generator (erpcgen) v1.8.0
  - Multicore Manager (MCMgr) v4.1.1
  - RPMsg-Lite v3.1.1

[2.8.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.7.4
  - eRPC generator (erpcgen) v1.7.4
  - Multicore Manager (MCMgr) v4.1.0
  - RPMsg-Lite v3.1.0

[2.7.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.7.3
  - eRPC generator (erpcgen) v1.7.3
  - Multicore Manager (MCMgr) v4.1.0
  - RPMsg-Lite v3.0.0

[2.6.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.7.2
  - eRPC generator (erpcgen) v1.7.2
  - Multicore Manager (MCMgr) v4.0.3
  - RPMsg-Lite v2.2.0

[2.5.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.7.1
  - eRPC generator (erpcgen) v1.7.1
  - Multicore Manager (MCMgr) v4.0.2
  - RPMsg-Lite v2.0.2

[2.4.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.7.0
  - eRPC generator (erpcgen) v1.7.0
  - Multicore Manager (MCMgr) v4.0.1
  - RPMsg-Lite v2.0.1

[2.3.1]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.6.0
  - eRPC generator (erpcgen) v1.6.0
  - Multicore Manager (MCMgr) v4.0.0
  - RPMsg-Lite v1.2.0

[2.3.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.5.0
  - eRPC generator (erpcgen) v1.5.0
  - Multicore Manager (MCMgr) v3.0.0
  - RPMsg-Lite v1.2.0

[2.2.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.4.0
  - eRPC generator (erpcgen) v1.4.0
  - Multicore Manager (MCMgr) v2.0.1
  - RPMsg-Lite v1.1.0

[2.1.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.3.0
  - eRPC generator (erpcgen) v1.3.0

[2.0.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.2.0
  - eRPC generator (erpcgen) v1.2.0
  - Multicore Manager (MCMgr) v2.0.0
  - RPMsg-Lite v1.0.0

[1.1.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.1.0
  - Multicore Manager (MCMgr) v1.1.0
  - Open-AMP / RPMsg based on SHA1 ID 44b5f3c0a6458f3cf80 rev01

[1.0.0]

- Multicore SDK component versions:
  - embedded Remote Procedure Call (eRPC) v1.0.0
  - Multicore Manager (MCMgr) v1.0.0
  - Open-AMP / RPMsg based on SHA1 ID 44b5f3c0a6458f3cf80 rev00

RPMSG-Lite

Quick links

- *Changelog*
- API documentation (Doxygen): https://nxp-mcuxpresso.github.io/rpmsg-lite/

This documentation describes the RPMsg-Lite component, which is a lightweight implementation of the Remote Processor Messaging (RPMsg) protocol. The RPMsg protocol defines a standardized binary interface used to communicate between multiple cores in a heterogeneous multicore system.

Compared to the RPMsg implementation of the Open Asymmetric Multi Processing (OpenAMP) framework (https://github.com/OpenAMP/open-amp), the RPMsg-Lite offers a code size reduction, API simplification, and improved modularity. On smaller Cortex-M0+ based systems, it is recommended to use RPMsg-Lite.

The RPMsg-Lite is an open-source component developed by NXP Semiconductors and released under the BSD-compatible license.

For overview please read RPMSG-Lite VirtIO Overview.

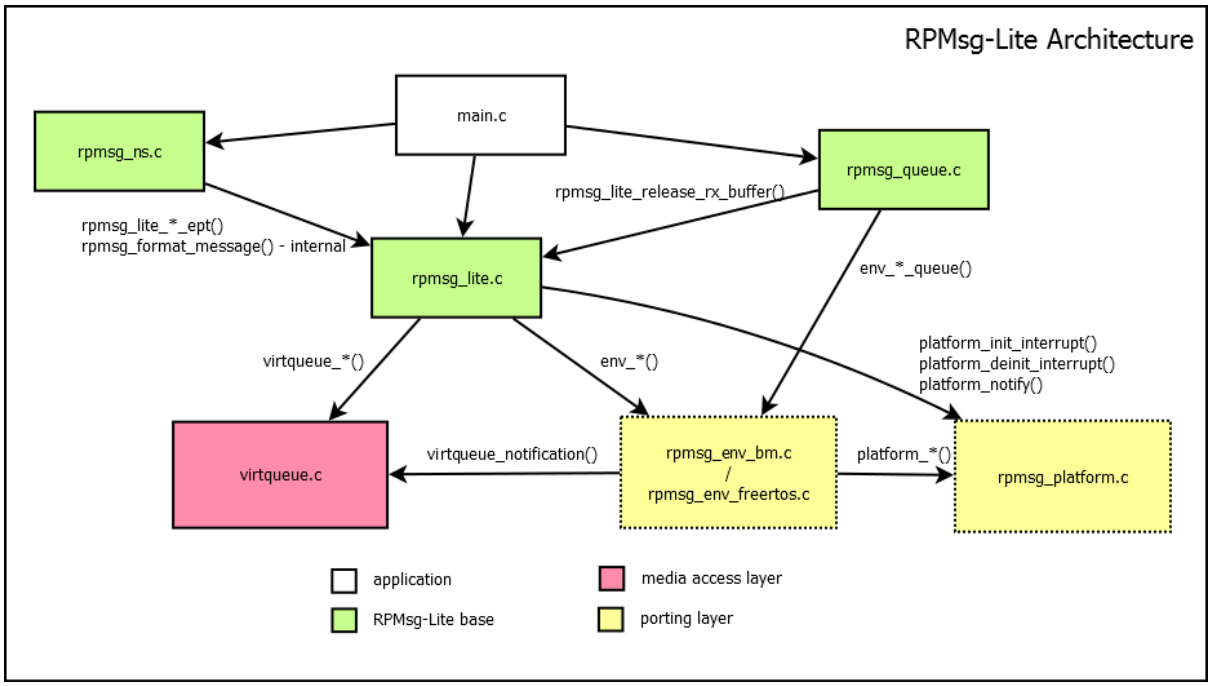
For RPMSG-Lite Design Considerations please read RPMSG-Lite Design Considerations.

Motivation to create RPMsg-Lite

There are multiple reasons why RPMsg-Lite was developed. One reason is the need for the small footprint of the RPMsg protocol-compatible communication component, another reason is the simplification of extensive API of OpenAMP RPMsg implementation.

RPMsg protocol was not documented, and its only definition was given by the Linux Kernel and legacy OpenAMP implementations. This has changed with [1] which is a standardization protocol allowing multiple different implementations to coexist and still be mutually compatible.

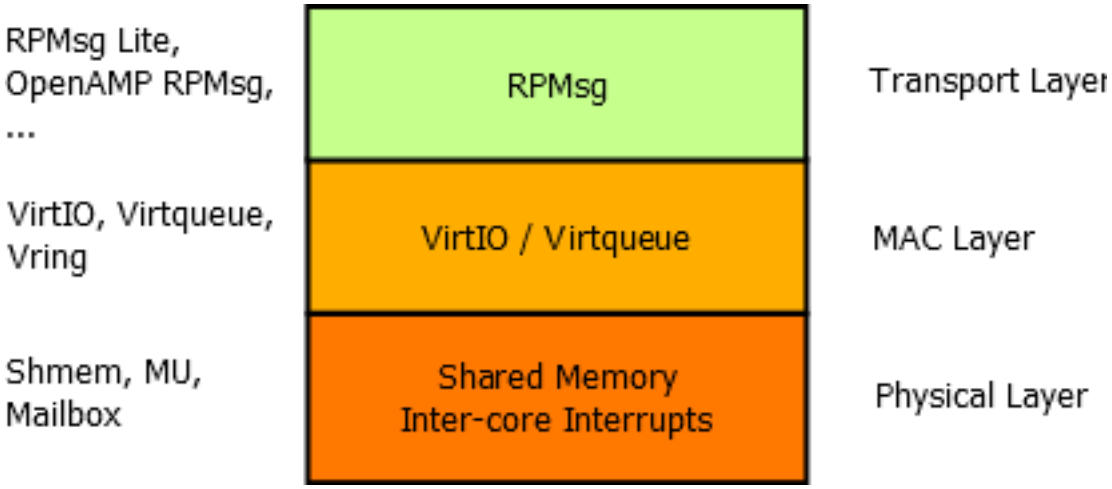
Small MCU-based systems often do not implement dynamic memory allocation. The creation of static API in RPMsg-Lite enables another reduction of resource usage. Not only does the dynamic allocation adds another 5 KB of code size, but also communication is slower and less deterministic, which is a property introduced by dynamic memory. The following table shows some rough comparison data between the OpenAMP RPMsg implementation and new RPMsg-Lite implementation:



Component / Configuration	Flash [B]	RAM [B]
OpenAMP RPMsg / Release (reference)	5547	456 + dynamic
RPMsg-Lite / Dynamic API, Release	3462	56 + dynamic
Relative Difference [%]	~62.4%	~12.3%
RPMsg-Lite / Static API (no malloc), Release	2926	352
Relative Difference [%]	~52.7%	~77.2%

Implementation

The implementation of RPMsg-Lite can be divided into three sub-components, from which two are optional. The core component is situated in rpmsg_lite.c. Two optional components are used to implement a blocking receive API (in rpmsg_queue.c) and dynamic “named” endpoint creation and deletion announcement service (in rpmsg_ns.c).



The actual “media access” layer is implemented in virtqueue.c, which is one of the few files shared with the OpenAMP implementation. This layer mainly defines the shared memory model, and internally defines used components such as vring or virtqueue.

The porting layer is split into two sub-layers: the environment layer and the platform layer. The first sublayer is to be implemented separately for each environment. (The bare metal environment already exists and is implemented in rpmsg_env_bm.c, and the FreeRTOS environment is implemented in rpmsg_env_freertos.c etc.) Only the source file, which matches the used environment, is included in the target application project. The second sublayer is implemented in rpmsg_platform.c and defines low-level functions for interrupt enabling, disabling, and triggering mainly. The situation is described in the following figure:

RPMsg-Lite core sub-component

This subcomponent implements a blocking send API and callback-based receive API. The RPMsg protocol is part of the transport layer. This is realized by using so-called endpoints. Each endpoint can be assigned a different receive callback function. However, it is important to notice that the callback is executed in an interrupt environment in current design. Therefore, certain actions like memory allocation are discouraged to execute in the callback. The following figure shows the role of RPMsg in an ISO/OSI-like layered model:

Queue sub-component (optional)

This subcomponent is optional and requires implementation of the env_*_queue() functions in the environment porting layer. It uses a blocking receive API, which is common in RTOS-environments. It supports both copy and nocopy blocking receive functions.

Name Service sub-component (optional)

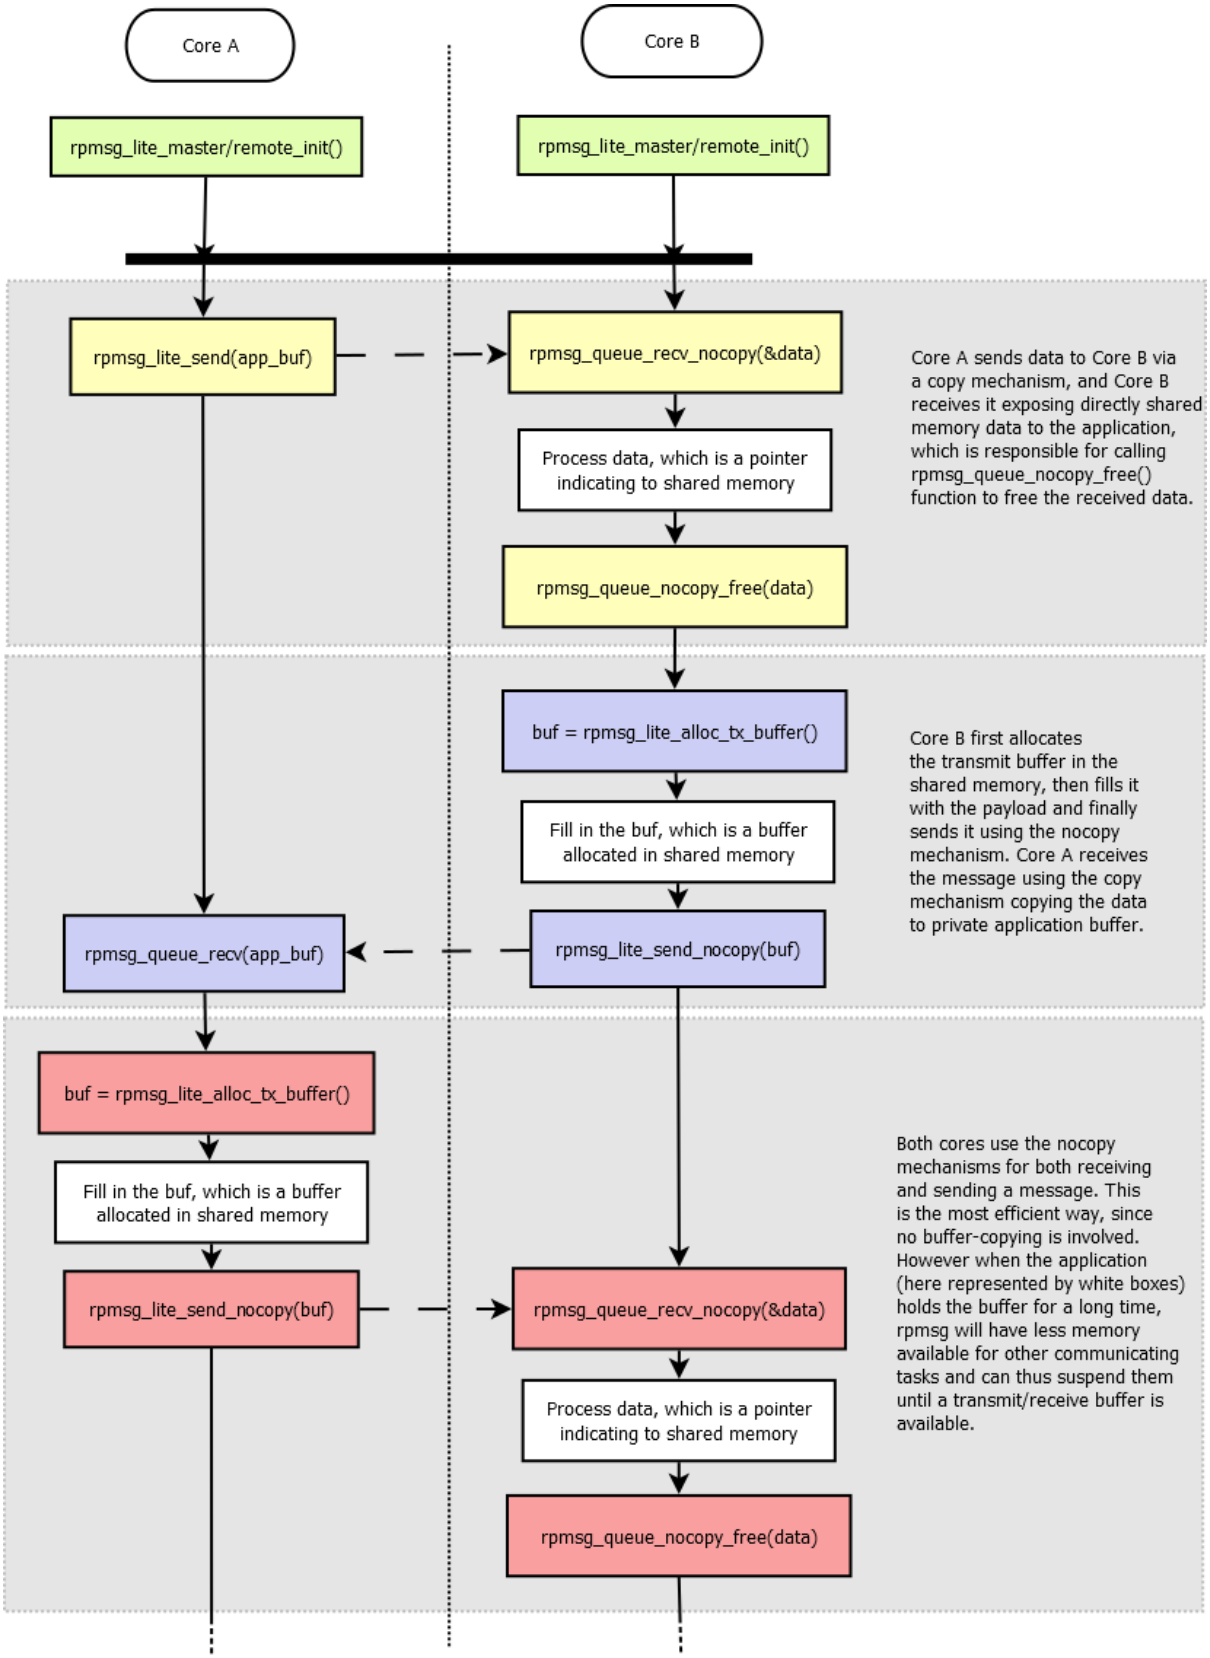
This subcomponent is a minimum implementation of the name service which is present in the Linux Kernel implementation of RPMsg. It allows the communicating node both to send announcements about “named” endpoint (in other words, channel) creation or deletion and to receive these announcement taking any user-defined action in an application callback. The endpoint address used to receive name service announcements is arbitrarily fixed to be 53 (0x35).

Usage

The application should put the /rpmsg_lite/lib/include directory to the include path and in the application, include either the rpmsg_lite.h header file, or optionally also include the rpmsg_queue.h and/or rpmsg_ns.h files. Both porting sublayers should be provided for you by NXP, but if you plan to use your own RTOS, all you need to do is to implement your own environment layer (in other words, rpmsg_env_myrtos.c) and to include it in the project build.

The initialization of the stack is done by calling the rpmsg_lite_master_init() on the master side and the rpmsg_lite_remote_init() on the remote side. This initialization function must be called prior to any RPMsg-Lite API call. After the init, it is wise to create a communication endpoint, otherwise communication is not possible. This can be done by calling the rpmsg_lite_create_ept() function. It optionally accepts a last argument, where an internal context of the endpoint is created, just in case the RL_USE_STATIC_API option is set to 1. If not, the stack internally calls env_alloc() to allocate dynamic memory for it. In case a callback-based receiving is to be used, an ISR-callback is registered to each new endpoint with user-defined callback data pointer. If a blocking receive is desired (in case of RTOS environment), the rpmsg_queue_create() function must be called before calling rpmsg_lite_create_ept(). The queue handle is passed to the endpoint creation function as a callback data argument and the callback function is set to rpmsg_queue_rx_cb(). Then, it is possible to use rpmsg_queue_receive() function to listen on a queue object for incoming messages. The rpmsg_lite_send() function is used to send messages to the other side.

The RPMsg-Lite also implements no-copy mechanisms for both sending and receiving operations. These methods require specifics that have to be considered when used in an application.



no-copy-send mechanism: This mechanism allows sending messages without the cost for copying data from the application buffer to the RPMsg/virtio buffer in the shared memory. The sequence of no-copy sending steps to be performed is as follows:

- Call the rpmsg_lite_alloc_tx_buffer() function to get the virtio buffer and provide the buffer pointer to the application.
- Fill the data to be sent into the pre-allocated virtio buffer. Ensure that the filled data does not exceed the buffer size (provided as the rpmsg_lite_alloc_tx_buffer() size output parameter).
- Call the rpmsg_lite_send_nocopy() function to send the message to the destination endpoint. Consider the cache functionality and the virtio buffer alignment. See the rpmsg_lite_send_nocopy() function description below.

no-copy-receive mechanism: This mechanism allows reading messages without the cost for copying data from the virtio buffer in the shared memory to the application buffer. The sequence of no-copy receiving steps to be performed is as follows:

- Call the rpmsg_queue_recv_nocopy() function to get the virtio buffer pointer to the received data.
- Read received data directly from the shared memory.
- Call the rpmsg_queue_nocopy_free() function to release the virtio buffer and to make it available for the next data transfer.

The user is responsible for destroying any RPMsg-Lite objects he has created in case of deinitialization. In order to do this, the function rpmsg_queue_destroy() is used to destroy a queue, rpmsg_lite_destroy_ept() is used to destroy an endpoint and finally, rpmsg_lite_deinit() is used to deinitialize the RPMsg-Lite intercore communication stack. Deinitialize all endpoints using a queue before deinitializing the queue. Otherwise, you are actively invalidating the used queue handle, which is not allowed. RPMsg-Lite does not check this internally, since its main aim is to be lightweight.

Examples

RPMsg_Lite multicore examples are part of NXP MCUXpressoSDK packages. Visit https://mcuxpresso.nxp.com to configure, build and download these packages. To get the board list with multicore support (RPMsg_Lite included) use filtering based on Middleware and search for

'multicore' string. Once the selected package with the multicore middleware is downloaded, see

<MCUXpressoSDK_install_dir>/boards/<board_name>/multicore_examples for RPMsg_Lite multicore examples with 'rpmsg_lite_' name prefix.

Another way of getting NXP MCUXpressoSDK RPMsg_Lite multicore examples is using the mcuxsdk-manifests Github repo. Follow the description how to use the West tool to clone and update the mcuxsdk-manifests repo in readme section. Once done the armgcc rpmsg_lite examples can be found in

mcuxsdk/examples/_<board_name>/multicore_examples

You can use the evkmimxrt1170 as the board_name for instance. Similar to MCUXpressoSDK packages the RPMsg_Lite examples use the 'rpmsg_lite_' name prefix.

Notes

Environment layers implementation

Several environment layers are provided in lib/rpmsg_lite/porting/environment folder. Not all of them are fully tested however. Here is the list of environment layers that passed testing:

- rpmsg_env_bm.c
- rpmsg_env_freertos.c
- rpmsg_env_xos.c
- rpmsg_env_threadx.c

The rest of environment layers has been created and used in some experimental projects, it has been running well at the time of creation but due to the lack of unit testing there is no guarantee it is still fully functional.

Shared memory configuration

It is important to correctly initialize/configure the shared memory for data exchange in the application. The shared memory must be accessible from both the master and the remote core and it needs to be configured as Non-Cacheable memory. Dedicated shared memory section in liker file is also a good practise, it is recommended to use linker files from MCUXpressSDK packages for NXP devices based applications. It needs to be ensured no other application part/component is unintentionally accessing this part of memory.

Configuration options

The RPMsg-Lite can be configured at the compile time. The default configuration is defined in the rpmsg_default_config.h header file. This configuration can be customized by the user by including rpmsg_config.h file with custom settings. The following table summarizes all possible RPMsg-Lite configuration options.

Configuration option	Default value	Usage
RL_MS_PE	(1)	Delay in milliseconds used in non-blocking API functions for polling.
RL_BUFFE	(496)	Size of the buffer payload, it must be more than 1 byte, and has to be word align (including rpmsg header size 16 bytes), if not it will be aligned up
RL_BUFFE	(2)	Number of the buffers, it must be power of two (2, 4, ...)
RL_API_H	(1)	Zero-copy API functions enabled/disabled.
RL_USE_S	(0)	Static API functions (no dynamic allocation) enabled/disabled.
RL_USE_D	(0)	Memory cache management of shared memory. Use in case of data cache is enabled for shared memory.
RL_CLEAF	(0)	Clearing used buffers before returning back to the pool of free buffers enabled/disabled.
RL_USE_M	(0)	When enabled IPC interrupts are managed by the Multicore Manager (IPC interrupts router), when disabled RPMsg-Lite manages IPC interrupts by itself.
RL_USE_E	(0)	When enabled the environment layer uses its own context. Required for some environments (QNX). The default value is 0 (no context, saves some RAM).
RL_DEBU(	(0)	When enabled buffer pointers passed to rpmsg_lite_send_nocopy() and rpmsg_lite_release_rx_buffer() functions (enabled by RL_API_HAS_ZEROCOPY config) are checked to avoid passing invalid buffer pointer. The default value is 0 (disabled). Do not use in RPMsg-Lite to Linux configuration.
RL_ALLO\	(0)	When enabled the opposite side is notified each time received buffers are consumed and put into the queue of available buffers. Enable this option in RPMsg-Lite to Linux configuration to allow unblocking of the Linux blocking send. The default value is 0 (RPMsg-Lite to RPMsg-Lite communication).
RL_ALLO\	(0)	It allows to define custom shared memory configuration and replacing the shared memory related global settings from rpmsg_config.h This is useful when multiple instances are running in parallel but different shared memory arrangement (vring size & alignment, buffers size & count) is required. The default value is 0 (all RPMsg_Lite instances use the same shared memory arrangement as defined by common config macros).
RL_ASSER	see rpmsg	Assert implementation.

How to format rpmsg-lite code

To format code, use the application developed by Google, named *clang-format*. This tool is part of the llvm project. Currently, the clang-format 10.0.0 version is used for rpmsg-lite. The set of style settings used for clang-format is defined in the `.clang-format` file, placed in a root of the rpmsg-lite directory where Python script `run_clang_format.py` can be executed. This script executes the application named *clang-format.exe*. You need to have the path of this application in the OS's environment path, or you need to change the script.

Changelog RPMSG-Lite

All notable changes to this project will be documented in this file.

The format is based on Keep a Changelog, and this project adheres to Semantic Versioning.

v5.5.0

Added

- Added MCXE32B dual Cortex-M7 parts support.
- Added rpmsg_lite_are_all_buffers_consumed() API to report when all locally allocated TX buffers were consumed by the peer and returned to the local free buffer pool, with test coverage in tests/03_send_receive for both sides.
- Added i.MX937 parts support
- Removed obsolete unused k32w1 platform layer

v5.4.1

Fixed

- Corrected isr_counter3 handling in RT700 porting layer platform_deinit_interrupt implementation.

v5.4.0

Added

- Added i.MX93W parts support
- Added i.MX952 parts support
- Added mcxl14x parts support
- Added mcxw70 parts support
- Zephyr rpmsg-lite samples add support for RT600 and RT700 DSP cores

Changed

- Port platform_get_custom_shmem_config change return value from uint32_t to int32_t for error handling consistency.

Fixed

- Updated unit tests code to allow correct GCOV code coverage measurement.
- Added missing dsb instructions into all ISRs for cm4/cm7 based platform layers.
- Fixed CERT EXP34-C by adding __attribute__((noreturn)) to RL_HANG(void) function.
- **MISRA C-2012 Rule 14.3 compliance**: Simplified RL_WORD_ALIGN_UP and RL_WORD_ALIGN_DOWN macros to eliminate invariant controlling expression violations (CID 5011148)
  - Replaced ternary operator implementations with standard bitwise alignment idioms
  - Fixed hardcoded 4U constant in RL_WORD_ALIGN_UP to use RL_WORD_SIZE for better portability
- Fixed several MISRA compliance violations

v5.3.0

Added

- RT700 porting layer added support to send rpmsg messages between CM33_0 <-> Hifi1 and CM33_1 <-> Hifi4 cores.
- Add new platform macro RL_PLATFORM_MAX_ISR_COUNT this will set number of IRQ count per platform. This macro is then used in environment layers to set isr_table size where irq handles are registered. It size should match the bit length of VQ_ID so all combinations can fit into table.
- Unit tests updated to improve code coverage, new unit tests added covering static allocations in rtos environment layers.

Fixed

- virtio.h removed typedef uint8_t boolean and in its place use standard C99 bool type to avoid potential type conflicts.
- env_acquire_sync_lock() and env_release_sync_lock() synchronization primitives removed
- Kconfig consolidation, when RL_ALLOW_CUSTOM_SHMEM_CONFIG enabled the platform_get_custom_shmem_config() function needs to be implemented in platform layer to provide custom shared memory configuration for RPMsg-Lite instance.

v5.2.1

Added

- Doc added RPMSG-Lite VirtIO Overview
- Doc added RPSMG-Lite Design Considerations
- Added frdmimxrt1186 unit testing

Changed

- Remove limitation that RL_BUFFER_SIZE needs to be power of 2. It just has to be more than 16 bytes, e.g. 16 bytes of rpmsg header and payload size at least 1 byte and word aligned, if not it will be aligned up.

Fixed

- Fixed CERT-C INT31-C violation in platform_notify function in rpmsg_platform.c for imxrt700_m33, imxrt700_hifi4, imxrt700_hifi1 platforms

v5.2.0

Added

- Add MCXL20 porting layer and unit testing
- New utility macro RL_CALCULATE_BUFFER_COUNT_DOWN_SAFE to safely determine maximum buffer count within shared memory while preventing integer underflow.
- RT700 platform add support for MCMGR in DSPs

Changed

- Change rpmsg_platform.c to support new MCMGR API
- Improved input validation in initialization functions to properly handle insufficient memory size conditions.
- Refactored repeated buffer count calculation pattern for better code maintainability.

- To make sure that remote has already registered IRQ there is required App level IPC mechanism to notify master about it

Fixed

- Fixed env_wait_for_link_up function to handle timeout in link state checks for baremetal and qnx environment, RL_BLOCK mode can be used to wait indefinitely.
- Fixed CERT-C INT31-C violation by adding compile-time check to ensure RL_PLATFORM_HIGHEST_LINK_ID remains within safe range for 16-bit casting in virtqueue ID creation.
- Fixed CERT-C INT30-C violations by adding protection against unsigned integer underflow in shared memory calculations, specifically in shmem_length - (uint32_t)RL_VRING_OVERHEAD and shmem_length - 2U * shmem_config.vring_size expressions.
- Fixed CERT INT31-C violation in platform_interrupt_disable() and similar functions by replacing unsafe cast from uint32_t to int32_t with a return of 0 constant.
- Fixed unsigned integer underflow in rpmsg_lite_alloc_tx_buffer() where subtracting header size from buffer size could wrap around if buffer was too small, potentially leading to incorrect buffer sizing.
- Fixed CERT-C INT31-C violation in rpmsg_lite.c where size parameter was cast from uint32_t to uint16_t without proper validation.
  - Applied consistent masking approach to both size and flags parameters: (uint16_t)(value & 0xFFFFU).
  - This fix prevents potential data loss when size values exceed 65535.
- Fixed CERT INT31-C violation in env_memset functions by explicitly converting int32_t values to unsigned char using bit masking. This prevents potential data loss or misinterpretation when passing values outside the unsigned char range (0-255) to the standard memset() function.
- Fixed CERT-C INT31-C violations in RPMsg-Lite environment porting: Added validation checks for signed-to-unsigned integer conversions to prevent data loss and misinterpretation.
  - rpmsg_env_freertos.c: Added validation before converting int32_t to UBaseType_t.
  - rpmsg_env_qnx.c: Fixed format string and added validation before assigning to mqstat fields.
  - rpmsg_env_threadx.c: Added validation to prevent integer overflow and negative values.
  - rpmsg_env_xos.c: Added range checking before casting to uint16_t.
  - rpmsg_env_zephyr.c: Added validation before passing values to k_msgq_init.
- Fixed a CERT INT31-C compliance issue in env_get_current_queue_size() function where an unsigned queue count was cast to a signed int32_t without proper validation, which could lead to lost or misinterpreted data if queue size exceeded INT32_MAX.
- Fixed CERT INT31-C violation in rpmsg_platform.c where memcmp() return value (signed int) was compared with unsigned constant without proper type handling.
- Fixed CERT INT31-C violation in rpmsg_platform.c where casting from uint32_t to uint16_t could potentially result in data loss. Changed length variable type from uint16_t to uint32_t to properly handle memory address differences without truncation.
- Fixed potential integer overflow in env_sleep_msec() function in ThreadX environment implementation by rearranging calculation order in the sleep duration formula.

- Fixed CERT-C INT31-C violation in RPMsg-Lite where bitwise NOT operations on integer constants were performed in signed integer context before being cast to unsigned. This could potentially lead to misinterpreted data on imx943 platform.
- Added RL_MAX_BUFFER_COUNT (32768U) and RL_MAX_VRING_ALIGN (65536U) limit to ensure alignment values cannot contribute to integer overflow
- Fixed CERT INT31-C violation in vring_need_event(), added cast to uint16_t for each operand.

v5.1.4 - 27-Mar-2025

Added

- Add KW43B43 porting layer

Changed

- Doxygen bump to version 1.9.6

v5.1.3 - 13-Jan-2025

Added

- Memory cache management of shared memory. Enable with #define RL_USE_DCACHE (1) in rpmsg_config.h in case of data cache is used.
- Cmake/Kconfig support added.
- Porting layers for imx95, imxrt700, mcmxw71x, mcmxw72x, kw47b42 added.

v5.1.2 - 08-Jul-2024

Changed

- Zephyr-related changes.
- Minor Misra corrections.

v5.1.1 - 19-Jan-2024

Added

- Test suite provided.
- Zephyr support added.

Changed

- Minor changes in platform and env. layers, minor test code updates.

v5.1.0 - 02-Aug-2023

Added

- RPMsg-Lite: Added aarch64 support.

Changed

- RPMsg-Lite: Increased the queue size to (2 * RL_BUFFER_COUNT) to cover zero copy cases.

- Code formatting using LLVM16.

Fixed

- Resolved issues in ThreadX env. layer implementation.

v5.0.0 - 19-Jan-2023

Added

- Timeout parameter added to rpmsg_lite_wait_for_link_up API function.

Changed

- Improved debug check buffers implementation - instead of checking the pointer fits into shared memory check the presence in the VirtIO ring descriptors list.
- VRING_SIZE is set based on number of used buffers now (as calculated in vring_init) - updated for all platforms that are not communicating to Linux rpmsg counterpart.

Fixed

- Fixed wrong RL_VRING_OVERHEAD macro comment in platform.h files
- Misra corrections.

v4.0.0 - 20-Jun-2022

Added

- Added support for custom shared memory arrangement per the RPMsg_Lite instance.
- Introduced new rpmsg_lite_wait_for_link_up() API function - this allows to avoid using busy loops in rtos environments, GitHub PR #21.

Changed

- Adjusted rpmsg_lite_is_link_up() to return RL_TRUE/RL_FALSE.

v3.2.0 - 17-Jan-2022

Added

- Added support for i.MX8 MP multicore platform.

Changed

- Improved static allocations - allow OS-specific objects being allocated statically, GitHub PR #14.
- Aligned rpmsg_env_xos.c and some platform layers to latest static allocation support.

Fixed

- Minor Misra and typo corrections, GitHub PR #19, #20.

v3.1.2 - 16-Jul-2021

Added

- Addressed MISRA 21.6 rule violation in rpmsg_env.h (use SDK's PRINTF in MCUXpressoSDK examples, otherwise stdio printf is used).
- Added environment layers for XOS.
- Added support for i.MX RT500, i.MX RT1160 and i.MX RT1170 multicore platforms.

Fixed

- Fixed incorrect description of the rpmsg_lite_get_endpoint_from_addr function.

Changed

- Updated RL_BUFFER_COUNT documentation (issue #10).
- Updated imxrt600_hifi4 platform layer.

v3.1.1 - 15-Jan-2021

Added

- Introduced RL_ALLOW_CONSUMED_BUFFERS_NOTIFICATION config option to allow opposite side notification sending each time received buffers are consumed and put into the queue of available buffers.
- Added environment layers for Threadx.
- Added support for i.MX8QM multicore platform.

Changed

- Several MISRA C-2012 violations addressed.

v3.1.0 - 22-Jul-2020

Added

- Added support for several new multicore platforms.

Fixed

- MISRA C-2012 violations fixed (7.4).
- Fixed missing lock in rpmsg_lite_rx_callback() for QNX env.
- Correction of rpmsg_lite_instance structure members description.
- Address -Waddress-of-packed-member warnings in GCC9.

Changed

- Clang update to v10.0.0, code re-formatted.

v3.0.0 - 20-Dec-2019

Added

- Added support for several new multicore platforms.

Fixed

- MISRA C-2012 violations fixed, incl. data types consolidation.

- Code formatted.

v2.2.0 - 20-Mar-2019

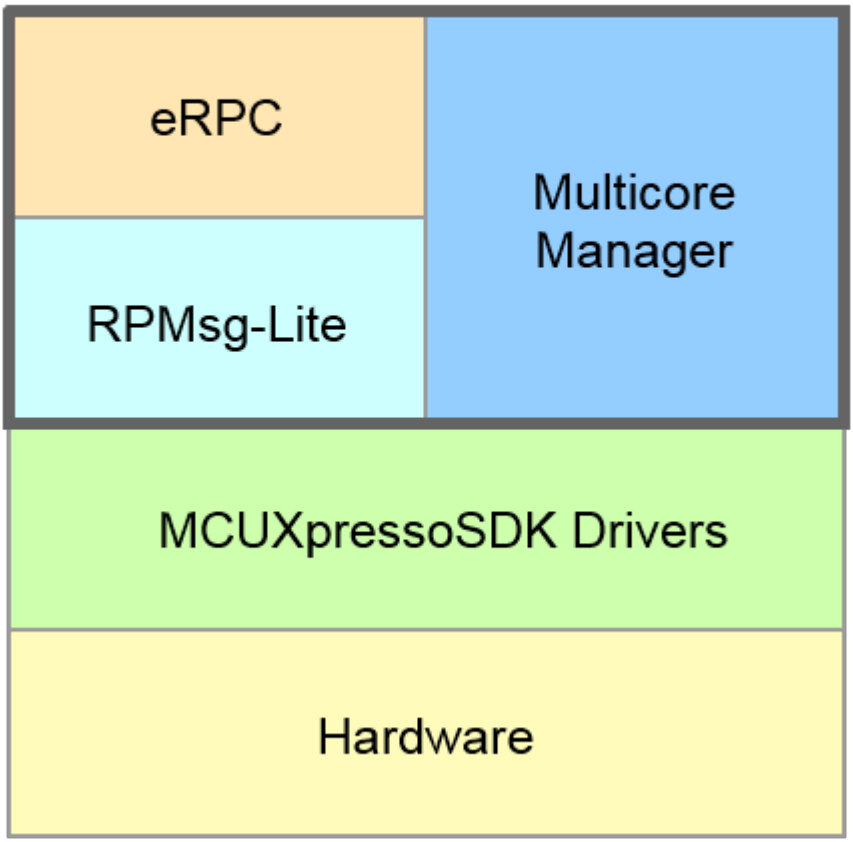
Added

- Added configuration macro RL_DEBUG_CHECK_BUFFERS.
- Several MISRA violations fixed.
- Added environment layers for QNX and Zephyr.
- Allow environment context required for some environment (controlled by the RL_USE_ENVIRONMENT_CONTEXT configuration macro).
- Data types consolidation.

v1.1.0 - 28-Apr-2017

Added

- Supporting i.MX6SX and i.MX7D MPU platforms.
- Supporting LPC5411x MCU platform.
- Baremental and FreeRTOS support.
- Support of copy and zero-copy transfer.
- Support of static API (without dynamic allocations).



Multicore Manager (MCMGR)

Quick links

- *Changelog*
- API documentation (Doxygen): https://nxp-mcuxpresso.github.io/mcux-mcmgr/

The Multicore Manager (MCMGR) software library provides a number of services for multicore systems. This library is distributed as a part of the Multicore SDK (MCSDK). Together, the MCSDK and the MCUXpresso SDK (SDK) form a framework for development of software for NXP multicore devices.

The MCMGR component is located in the <MCUXpressoSDK_install_dir>/middleware/multicore/mcmgr directory.

The Multicore Manager provides the following major functions:

- Maintains information about all cores in system.
- Secondary/auxiliary core(s) startup and shutdown.
- Remote core monitoring and event handling.

Usage of the MCMGR software component

The main use case of MCMGR is the secondary/auxiliary core start. This functionality is performed by the public API function.

Example of MCMGR usage to start secondary core:

```
#include "mcmgr.h"

void main()
{
    /* Initialize MCMGR, low level multicore management library */
    MCMGR_Init();

    /* Boot secondary core application from the CORE1_BOOT_ADDRESS, pass "1" as startup data,␣
↪starting synchronously. */
    MCMGR_StartCore(kMCMGR_Core1, CORE1_BOOT_ADDRESS, 1, kMCMGR_Start_Synchronous);
```

(continues on next page)

(continued from previous page)

```
.
.
.
    /* Stop secondary core execution. */
    MCMGR_StopCore(kMCMGR_Core1);
}
```

Some platforms allow stopping and re-starting the secondary core application again, using the MCMGR_StopCore / MCMGR_StartCore API calls. It is necessary to ensure the initially loaded image is not corrupted before re-starting, especially if it deals with the RAM target. Cache coherence has to be considered/ensured as well.

It could also happen that the secondary core application stops running correctly and the primary core application does not know about that situation. Therefore, it is beneficial to implement a mechanism for core health monitoring. The test_heartbeat unit test can serve as an example how to ensure that: secondary core could periodically send heartbeat signals to the primary core using MCMGR_TriggerEvent() API to indicate that it is alive and functioning properly.

Another important MCMGR feature is the ability for remote core monitoring and handling of events such as reset, exception, and application events. Application-specific callback functions for events are registered by the MCMGR_RegisterEvent() API. Triggering these events is done using the MCMGR_TriggerEvent() API. mcmgr_event_type_t enums all possible event types.

An example of MCMGR usage for remote core monitoring and event handling. Code for the primary side:

```
#include "mcmgr.h"

#define APP_RPMSG_READY_EVENT_DATA  (1)
#define APP_NUMBER_OF_CORES (2)
#define APP_SECONDARY_CORE kMCMGR_Core1

/* Callback function registered via the MCMGR_RegisterEvent() and triggered by MCMGR_TriggerEvent()␣
↪called on the secondary core side */
void RPMsgRemoteReadyEventHandler(mcmgr_core_t coreNum, uint16_t eventData, void *context)
{
    uint16_t *data = &((uint16_t *)context)[coreNum];

    *data = eventData;
}

void main()
{
    uint16_t RPMsgRemoteReadyEventData[NUMBER_OF_CORES] = {0};

    /* Initialize MCMGR, low level multicore management library */
    MCMGR_Init();

    /* Register the application event before starting the secondary core */
    MCMGR_RegisterEvent(kMCMGR_RemoteApplicationEvent, RPMsgRemoteReadyEventHandler, (void␣
↪*)RPMsgRemoteReadyEventData);

    /* Boot secondary core application from the CORE1_BOOT_ADDRESS, pass rpmsg_lite_base address␣
↪as startup data, starting synchronously. */
    MCMGR_StartCore(APP_SECONDARY_CORE, CORE1_BOOT_ADDRESS, (uint32_t)rpmsg_lite_
↪base, kMCMGR_Start_Synchronous);

    /* Wait until the secondary core application signals the rpmsg remote has been initialized and is ready to␣
↪communicate. */
    while(APP_RPMSG_READY_EVENT_DATA != RPMsgRemoteReadyEventData[APP_SECONDARY_
↪CORE]) {};
```

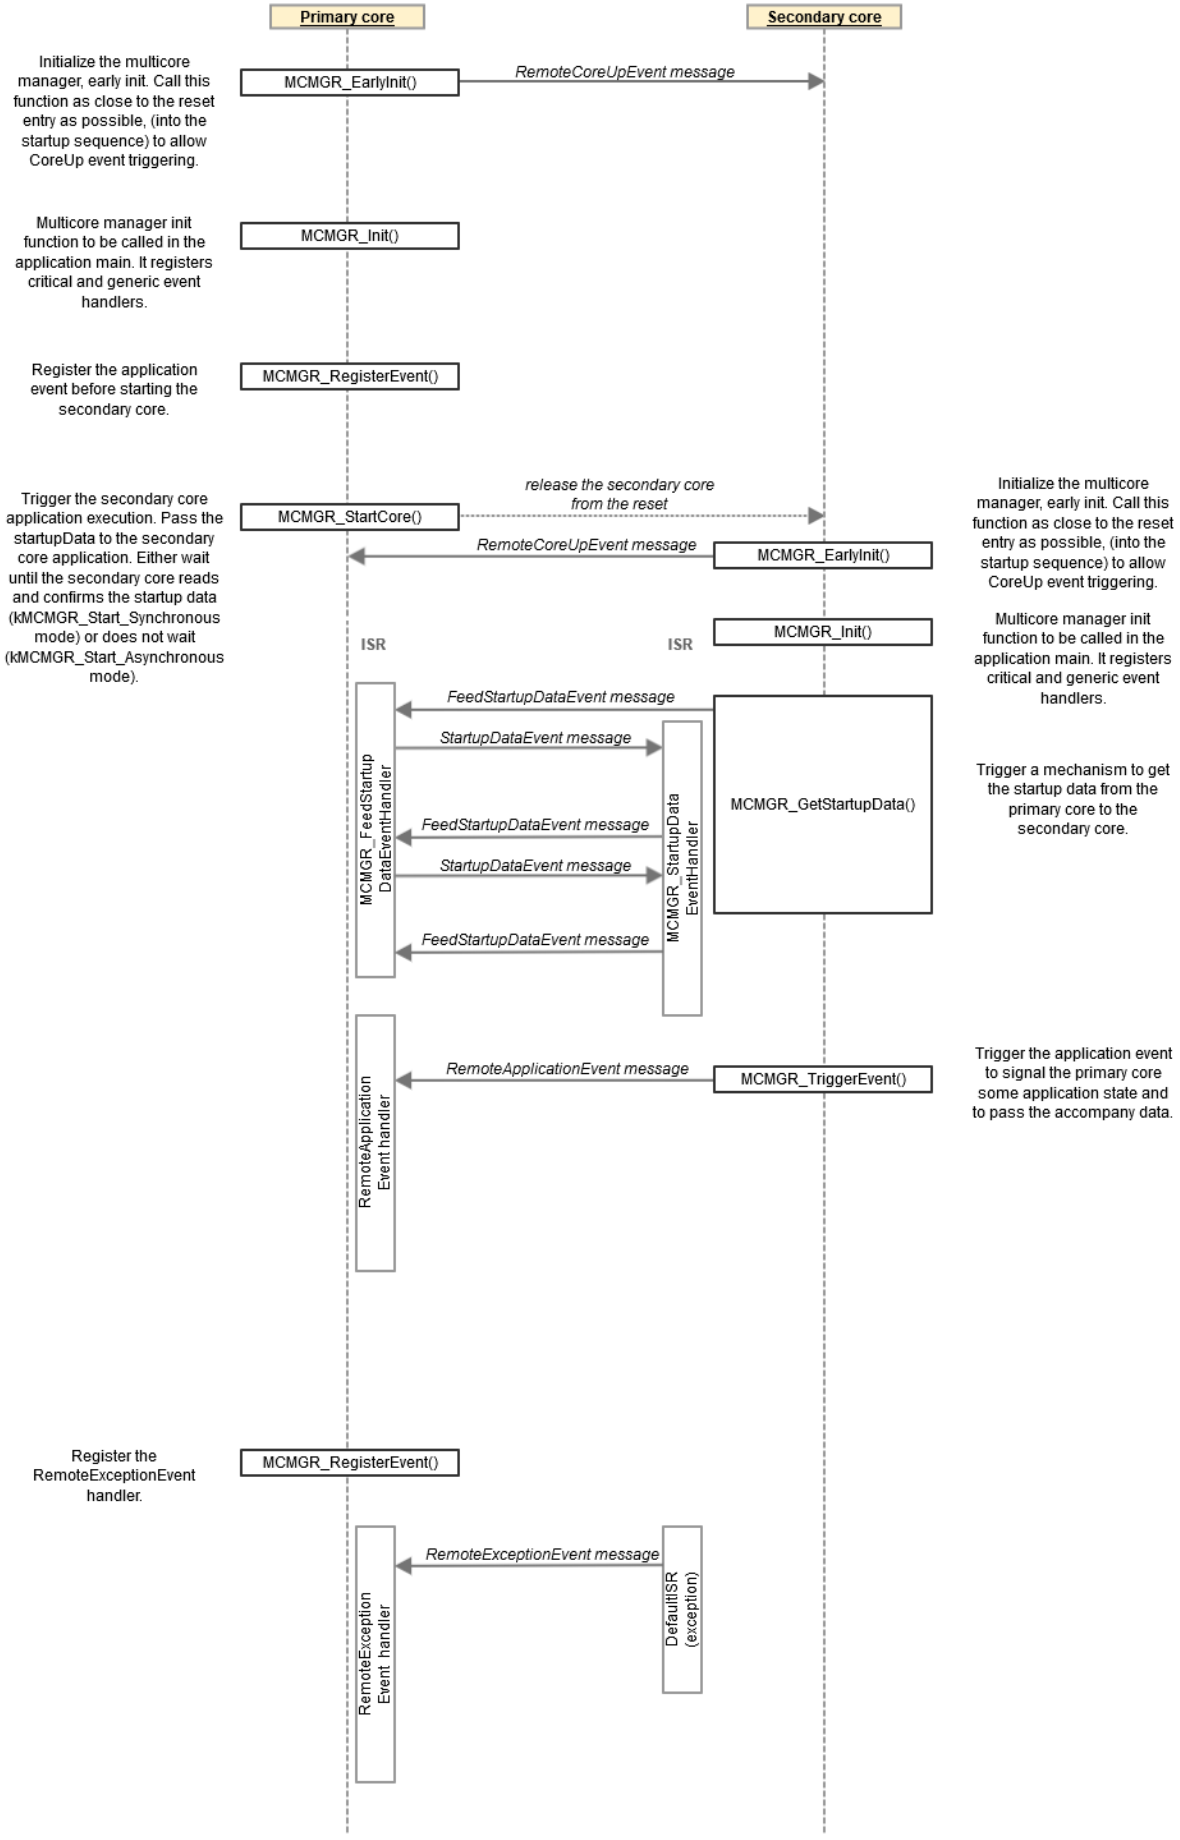
(continues on next page)

(continued from previous page)

```
.
.
.
}
```

Code for the secondary side:

```
#include "mcmgr.h"



#define APP_RPMSG_READY_EVENT_DATA  (1)

void main()
{
    /* Initialize MCMGR, low level multicore management library */
    MCMGR_Init();
.
.
.

    /* Signal the to other core that we are ready by triggering the event and passing the APP_RPMSG_
↪READY_EVENT_DATA */
    MCMGR_TriggerEvent(kMCMGR_Core0, kMCMGR_RemoteApplicationEvent, APP_RPMSG_
↪READY_EVENT_DATA);
.
.
.
}
```

MCMGR Data Exchange Diagram

The following picture shows how the handshakes are supposed to work between the two cores in the MCMGR software.

Primary core
Secondary core
Initialize the multicore manager, early init. Call this function as close to the reset entry as possible, (into the startup sequence) to allow CoreUp event triggering.
MCMGR_EarlyInit()
RemoteCoreUpEvent message
Multicore manager init function to be called in the application main. It registers critical and generic event handlers.
MCMGR_Init()
Register the application event before starting the secondary core.
MCMGR_RegisterEvent()
Trigger the secondary core application execution. Pass the startupData to the secondary core application. Either wait until the secondary core reads and confirms the startup data (kMCMGR_Start_Synchronous mode) or does not wait (kMCMGR_Start_Asynchronous mode).
MCMGR_StartCore()
release the secondary core from the reset
RemoteCoreUpEvent message
MCMGR_EarlyInit()
Initialize the multicore manager, early init. Call this function as close to the reset entry as possible, (into the startup sequence) to allow CoreUp event triggering.
MCMGR_Init()
Multicore manager init function to be called in the application main. It registers critical and generic event handlers.
ISR
ISR
FeedStartupDataEvent message
StartupDataEvent message
FeedStartupDataEvent message
StartupDataEvent message
FeedStartupDataEvent message
MCMGR_FeedStartup DataEventHandler
MCMGR_StartupData EventHandler
MCMGR_GetStartupData()
Trigger a mechanism to get the startup data from the primary core to the secondary core.
RemoteApplicationEvent message
MCMGR_TriggerEvent()
RemoteApplication Event handler
Trigger the application event to signal the primary core some application state and to pass the accompany data.
Register the RemoteExceptionEvent handler.
MCMGR_RegisterEvent()
RemoteExceptionEvent message
RemoteException Event handler
DefaultISR (exception)

Changelog Multicore Manager

All notable changes to this project will be documented in this file.

The format is based on Keep a Changelog, and this project adheres to Semantic Versioning.

v5.3.0

Added

- Added MCXE32B (dual Cortex-M7) porting layer.
- Remove obsolete unused platform layers
- Added initialization guard to public MCMGR API functions (RPSDK-1183): guarded functions return kStatus_MCMGR_NotReady before MCMGR_Init() completes.

Fixed

- MCUX-88924: Fix KW43 ICS init-handshake hang (RPSDK-1183 regression): s_mcmgrInitialized is now set before mcmgr_platform_init_internal() enables the MU RX IRQ, so re-entrant ISR dispatch during MCMGR_Init() is no longer silently dropped by MCMGR_CHECK_INIT().
- MCUX-89876: Fix Coverity DEADCODE and UNUSED_VALUE findings in mcmgr_internal_core_api_imxrt700.c: align mcmgr_mu_channel_handler event-range guard with positive-logic form (matching imxrt1170), and aggregate mcmgr_trigger_event_internal return values in mcmgr_platform_init_internal_early so earlier errors are not silently overwritten.

v5.2.0

Changed

- Merged internal platform initialization into a single $\mathrm{mcmgr\_platform\_init\_internal()}$ function.
- Simplified initialization API: $\mathrm{MCMGR\_Init()}$ now handles both early and standard initialization internally.

Deprecated

- $\mathrm{MCMGR\_EarlyInit()}$ is now deprecated and a no-op. It remains for backward compatibility and may be removed in a future major version. Replace calls to $\mathrm{MCMGR\_EarlyInit()}$ + $\mathrm{MCMGR\_Init()}$ with a single $\mathrm{MCMGR\_Init()}$ call.

Migration Guide

Before:

```
MCMGR_EarlyInit();
// ...
MCMGR_Init();
```

After:

```
MCMGR_Init();
```

v5.1.0

Added

- Added mcxl14x parts support
- Added mcxw70 parts support
- Add new config MCMGR_REMOTE_APP_EVENT_COUNT for configurable remote application event count. This will expand number of application events available for MCMGR users. kMCMGR_RemoteApplicationEvent, kMCMGR_RemoteApplicationEvent1 .. kMCMGR_RemoteApplicationEvent4.
- Align Kinetis parts porting to changed register map

Fixed

- Fix MISRA C-2012 Rule 20.8 violations.

v5.0.2

Added

- Added gcov options and configs to support mcmgr code coverage
- Added new test_weak_mu_isr testcase for devices with MU peripheral
- Added new test_heartbeat testcase showing heartbeat mechanism between primary and secondary cores using the MCMGR

v5.0.1

Added

- Added frdmimxrt1186 unit testing

Changed

- [KW43] Rename core#1 reset control register

Fixed

- Added CX flag into CMakeLists.txt to allow c++ build compatibility.
- Fix path to mcmgr headers directory in doxyfile

v5.0.0

Added

- Added MCMGR_BUSY_POLL_COUNT macro to prevent infinite polling loops in MCMGR operations.
- Implemented timeout mechanism for all polling loops in MCMGR code.
- Added support to handle more then two cores. Breaking API change by adding parameter coreNum specifying core number in functions bellow.
  - MCMGR_GetStartupData(uint32_t *startupData, mcmgr_core_t coreNum)
  - MCMGR_TriggerEvent(mcmgr_event_type_t type, uint16_t eventData, mcmgr_core_t coreNum)
  - MCMGR_TriggerEventForce(mcmgr_event_type_t type, uint16_t eventData, mcmgr_core_t coreNum)
  - typedef void (*mcmgr_event_callback_t)(uint16_t data, void *context, mcmgr_core_t coreNum);

When registering the event with function MCMGR_RegisterEvent() user now needs to provide callbackData pointer to array of elements per every core in system (see README.md for example).In case of systems with only two cores the coreNum in callback can be ignored as events can arrive only from one core. Please see Porting guide for more details: Porting-GuideTo_v5.md

- Updated all porting files to support new MCMGR API.
- Added new platform specific include file mcmgr_platform.h. It will contain common platform specific macros that can be then used in mcmgr and application. e.g. platform core count MCMGR_CORECOUNT 4.
- Move all header files to new inc directory.
- Added new platform-specific include files inc/platform/<platform_name>/mcmgr_platform.h.

Added

- Add MCXL20 porting layer and unit testing

v4.1.7

Fixed

- mcmgr_stop_core_internal() function now returns kStatus_MCMGR_NotImplemented status code instead of kStatus_MCMGR_Success when device does not support stop of secondary core. Ports affected: kw32w1, kw45b41, kw45b42, mcxw716, mcxw727.

[v4.1.6]

Added

- Multicore Manager moved to standalone repository.
- Add porting layers for imxrt700, mcmxw727, kw47b42.
- New MCMGR_ProcessDeferredRxIsr() API added.

[v4.1.5]

Added

- Add notification into MCMGR_EarlyInit and mcmgr_early_init_internal functions to avoid using uninitialized data in their implementations.

[v4.1.4]

Fixed

- Avoid calling tx isr callbacks when respective Messaging Unit Transmit Interrupt Enable flag is not set in the CR/TCR register.
- Messaging Unit RX and status registers are cleared after the initialization.

[v4.1.3]

Added

- Add porting layers for imxrt1180.

Fixed

- mu_isr() updated to avoid calling tx isr callbacks when respective Transmit Interrupt Enable flag is not set in the CR/TCR register.
- mcmgr_mu_internal.c code adaptation to new supported SoCs.

[v4.1.2]

Fixed

- Update mcmgr_stop_core_internal() implementations to set core state to kMCMGR_ResetCoreState.

[v4.1.0]

Fixed

- Code adjustments to address MISRA C-2012 Rules

[v4.0.3]

Fixed

- Documentation updated to describe handshaking in a graphic form.
- Minor code adjustments based on static analysis tool findings

[v4.0.2]

Fixed

- Align porting layers to the updated MCUXpressoSDK feature files.

[v4.0.1]

Fixed

- Code formatting, removed unused code

[v4.0.0]

Added

- Add new MCMGR_TriggerEventForce() API.

[v3.0.0]

Removed

- Removed MCMGR_LoadApp(), MCMGR_MapAddress() and MCMGR_SignalReady()

Modified

- Modified MCMGR_GetStartupData()

Added

- Added MCMGR_EarlyInit(), MCMGR_RegisterEvent() and MCMGR_TriggerEvent()
- Added the ability for remote core monitoring and event handling

[v2.0.1]

Fixed

- Updated to be Misra compliant.

[v2.0.0]

Added

- Support for lpcxpresso54114 board.

[v1.1.0]

Fixed

- Ported to KSDK 2.0.0.

[v1.0.0]

Added

- Initial release.

eRPC

eRPC (Embedded RPC) is an open-source remote procedure call (RPC) system suitable for multi-core and multiprocessor embedded systems.

Quick links

- *Getting Started*
- *Changelog*
- Upstream project: https://github.com/EmbeddedRPC/erpc

eRPC Getting Started

Overview

This *Getting Started User Guide* shows software developers how to use Remote Procedure Calls (RPC) in embedded multicore microcontrollers (eRPC).

The eRPC documentation is located in the *<MCUXpressoSDK_install_dir>/ middleware/multicore/erpc/doc* folder.

Create an eRPC application

This section describes a generic way to create a client/server eRPC application:

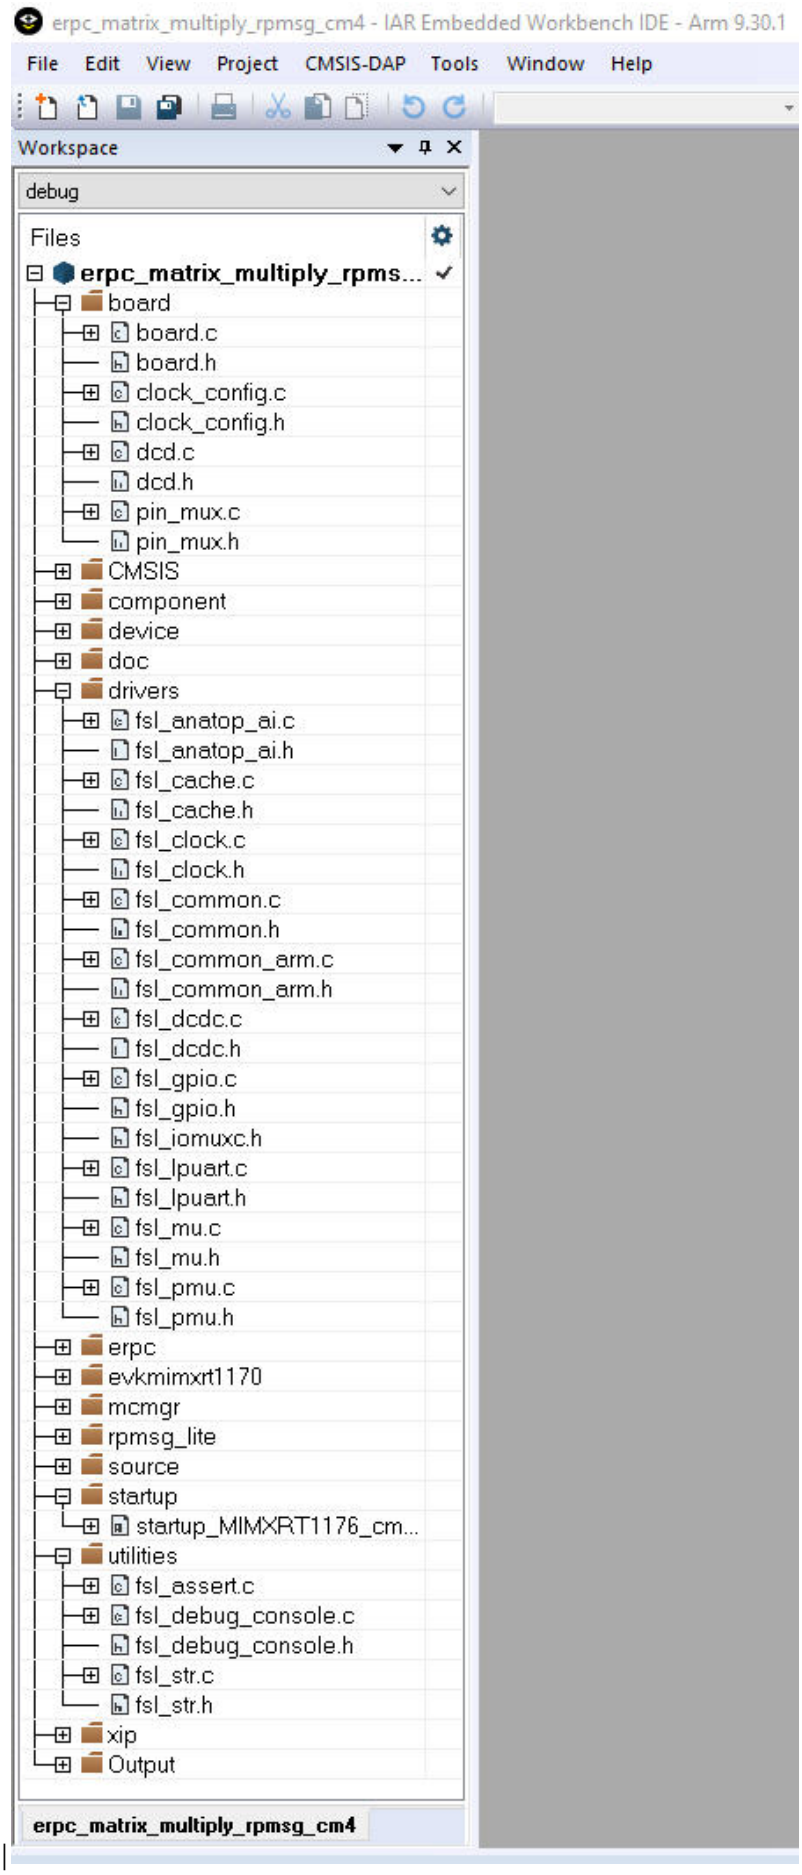
1. **Design the eRPC application:** Decide which data types are sent between applications, and define functions that send/receive this data.

2. **Create the IDL file:** The IDL file contains information about data types and functions used in an eRPC application, and is written in the IDL language.
3. **Use the eRPC generator tool:** This tool takes an IDL file and generates the shim code for the client and the server-side applications.
4. **Create an eRPC application:**
    1. Create two projects, where one project is for the client side (primary core) and the other project is for the server side (secondary core).
    2. Add generated files for the client application to the client project, and add generated files for the server application to the server project.
    3. Add infrastructure files.
    4. Add user code for client and server applications.
    5. Set the client and server project options.
5. **Run the eRPC application:** Run both the server and the client applications. Make sure that the server has been run before the client request was sent.

A specific example follows in the next section.

Multicore server application

The “Matrix multiply” eRPC server project is located in the following folder:



<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_examples/erpc_matrix_multiply_rpmsg/cm4/iar

The project files for the eRPC server have the $\_\mathrm{cm4}$ suffix.

Server project basic source files

The startup files, board-related settings, peripheral drivers, and utilities belong to the basic project source files and form the skeleton of all MCUXpresso SDK applications. These source files are located in:

- *<MCUXpressoSDK_install_dir>/devices/<device>*
- *<MCUXpressoSDK_install_dir>/boards/<board_name>/multicore_examples/<example_name>/*

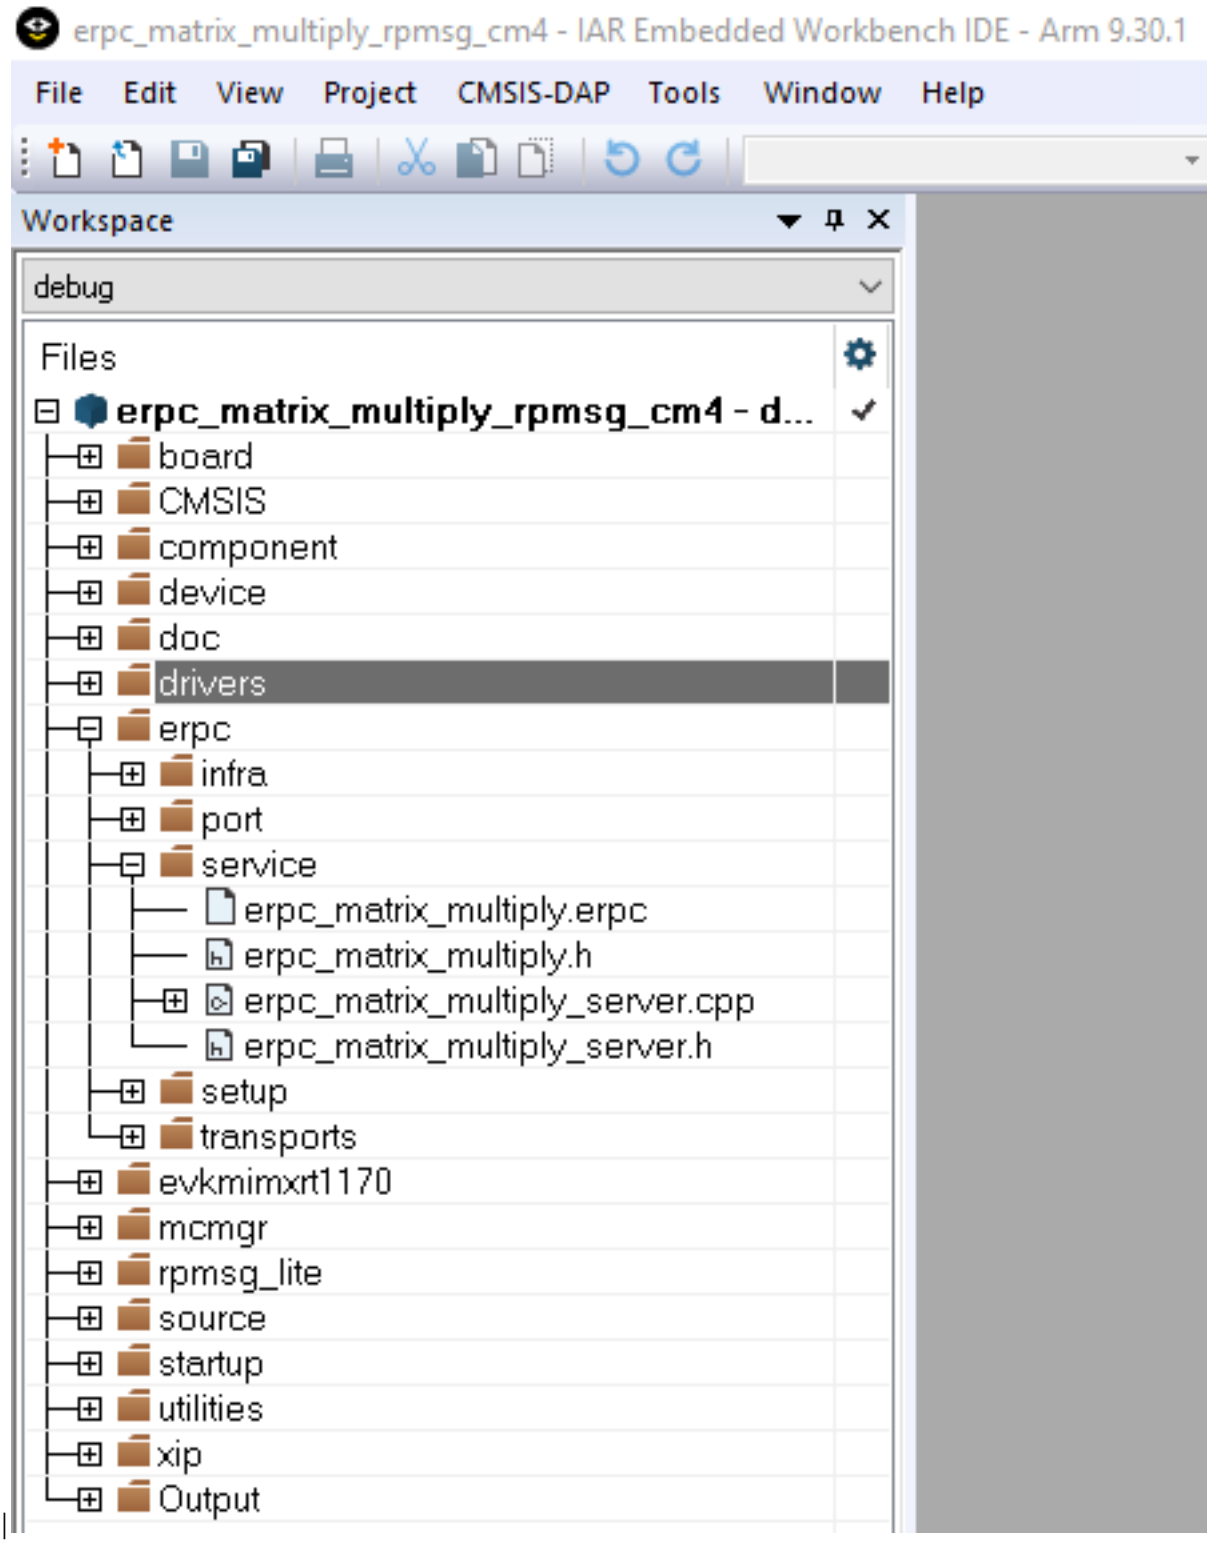
Parent topic: Multicore server application



Server related generated files

The server-related generated files are:

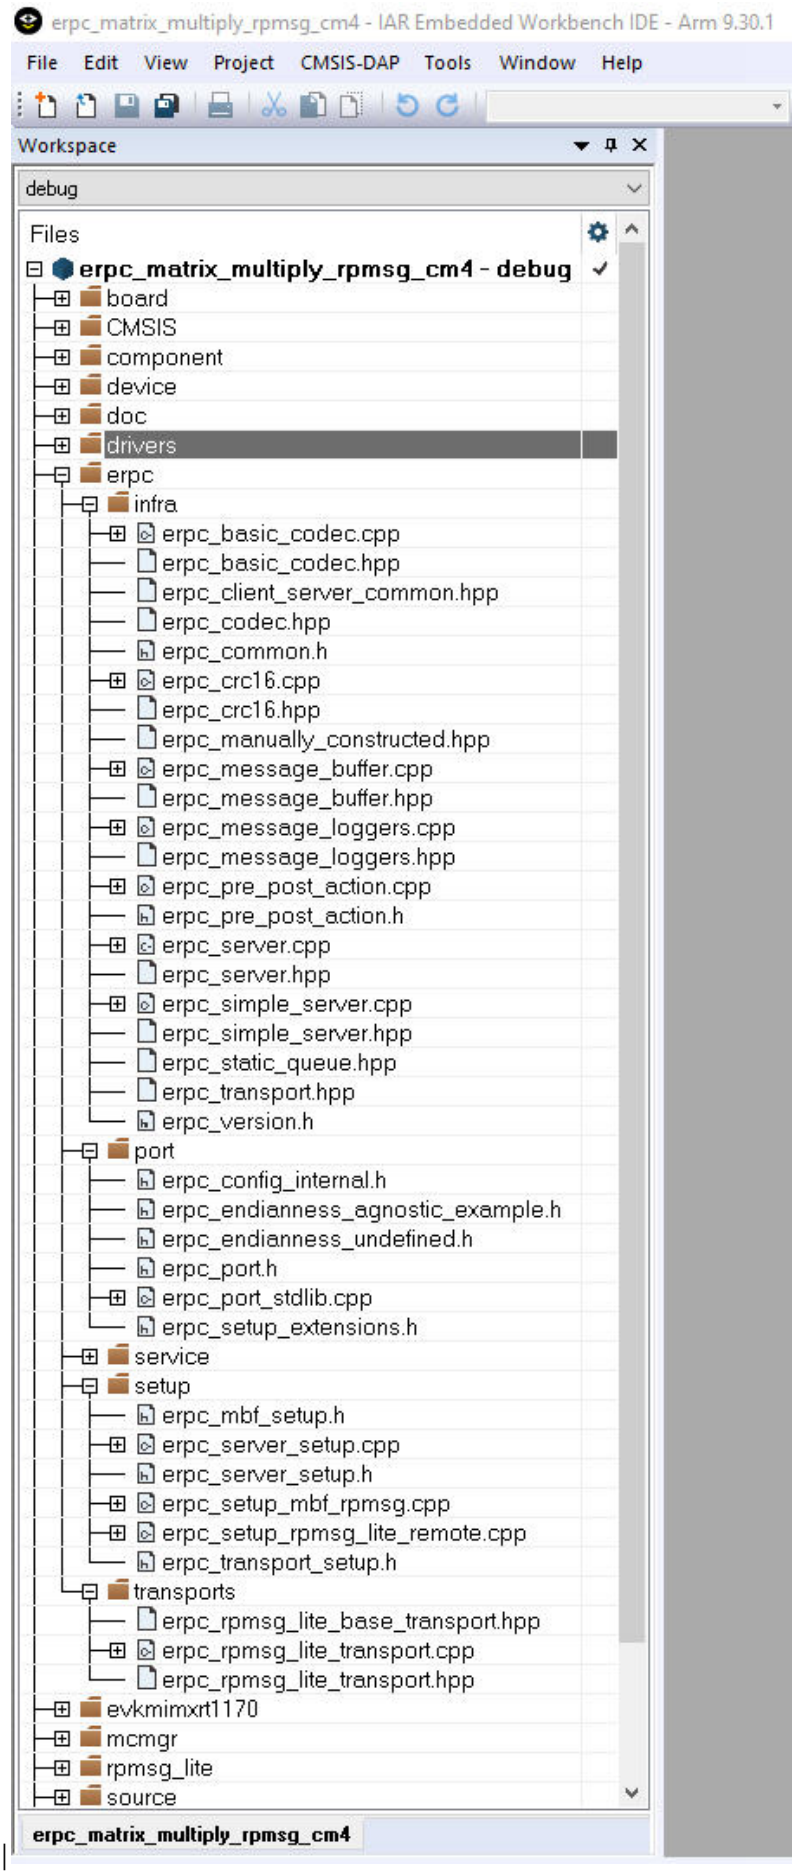
- erpc_matric_multiply.h
- erpc_matrix_multiply_server.h
- erpc_matrix_multiply_server.cpp

The server-related generated files contain the shim code for functions and data types declared in the IDL file. These files also contain functions for the identification of client requested functions, data deserialization, calling requested function's implementations, and data serialization and return, if requested by the client. These shim code files can be found in the following folder:

<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_examples/erpc_common/erpc_matrix_multiply/s

Parent topic: Multicore server application

Server infrastructure files



The eRPC infrastructure files are located in the following folder:

<MCUXpressoSDK_install_dir>/middleware/multicore/erpc/erpc_c

The **erpc_c** folder contains files for creating eRPC client and server applications in the *C/C++*

language. These files are distributed into subfolders.

- The **infra** subfolder contains C++ infrastructure code used to build server and client applications.
  - Four files, erpc_server.hpp, erpc_server.cpp, erpc_simple_server.hpp, and erpc_simple_server.cpp, are used for running the eRPC server on the server-side applications. The simple server is currently the only implementation of the server, and its role is to catch client requests, identify and call requested functions, and send data back when requested.
  - Three files (erpc_codec.hpp, erpc_basic_codec.hpp, and erpc_basic_codec.cpp) are used for codecs. Currently, the basic codec is the initial and only implementation of the codecs.
  - The erpc_common.hpp file is used for common eRPC definitions, typedefs, and enums.
  - The erpc_manually_constructed.hpp file is used for allocating static storage for the used objects.
  - Message buffer files are used for storing serialized data: erpc_message_buffer.h and erpc_message_buffer.cpp.
  - The erpc_transport.h file defines the abstract interface for transport layer.
- The **port** subfolder contains the eRPC porting layer to adapt to different environments.
  - erpc_port.h file contains definition of erpc_malloc() and erpc_free() functions.
  - erpc_port_stdlib.cpp file ensures adaptation to stdlib.
  - erpc_config_internal.h internal erpc configuration file.
- The **setup** subfolder contains a set of plain C APIs that wrap the C++ infrastructure, providing client and server init and deinit routines that greatly simplify eRPC usage in C-based projects. No knowledge of C++ is required to use these APIs.
  - The erpc_server_setup.h and erpc_server_setup.cpp files needs to be added into the "Matrix multiply" example project to demonstrate the use of C-wrapped functions in this example.
  - The erpc_transport_setup.h and erpc_setup_rpmsg_lite_remote.cpp files needs to be added into the project in order to allow the C-wrapped function for transport layer setup.
  - The erpc_mbf_setup.h and erpc_setup_mbf_rpmsg.cpp files needs to be added into the project in order to allow message buffer factory usage.
- The **transports** subfolder contains transport classes for the different methods of communication supported by eRPC. Some transports are applicable only to host PCs, while others are applicable only to embedded or multicore systems. Most transports have corresponding client and server setup functions in the setup folder.
  - RPMsg-Lite is used as the transport layer for the communication between cores, erpc_rpmsg_lite_base_transport.hpp, erpc_rpmsg_lite_transport.hpp, and erpc_rpmsg_lite_transport.cpp files need to be added into the server project.

Server multicore infrastructure files

Because of the RPMsg-Lite (transport layer), it is also necessary to include RPMsg-Lite related files, which are in the following folder:

<MCUXpressoSDK_install_dir>/middleware/multicore/rpmsg_lite/

The multicore example applications also use the Multicore Manager software library to control the secondary core startup and shutdown. These source files are located in the following folder:

<MCUXpressoSDK_install_dir>/middleware/multicore/mcmgr/

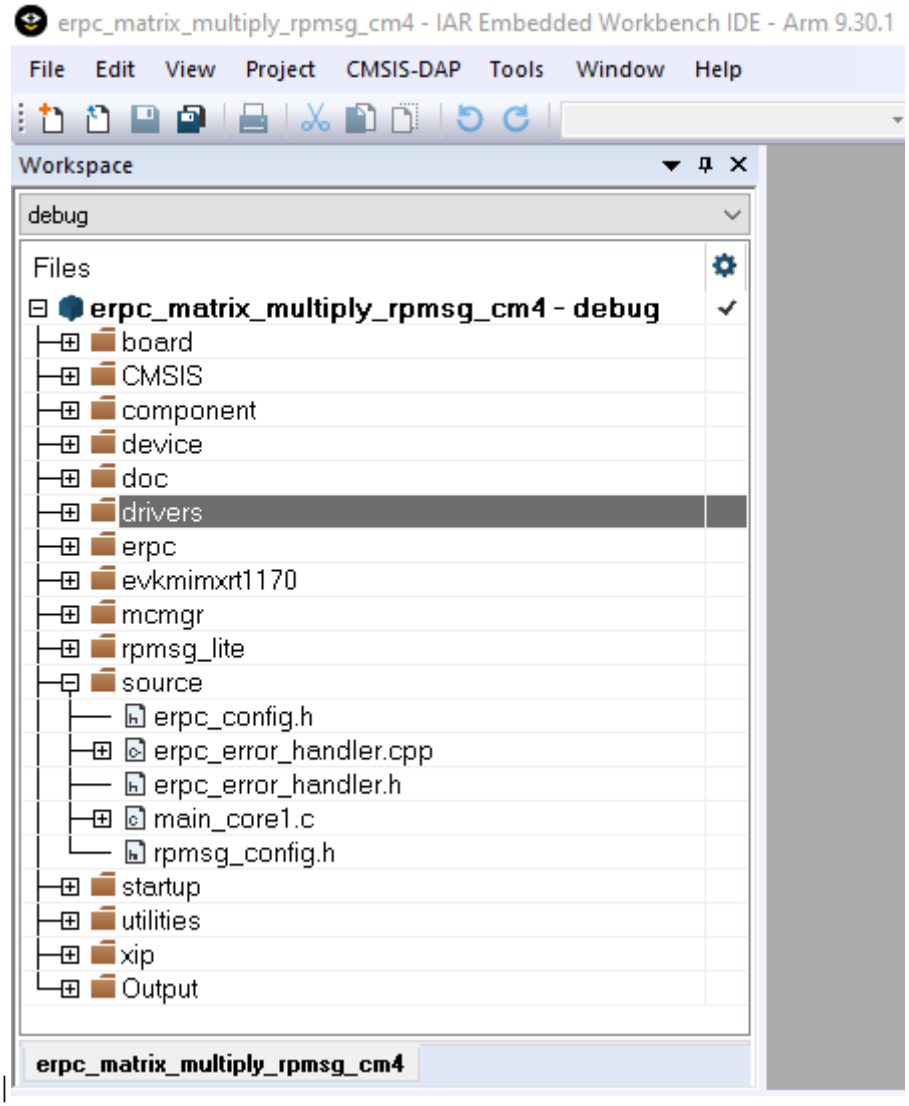
Parent topic: Multicore server application

Server user code

The server's user code is stored in the main_core1.c file, located in the following folder:

<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_examples/erpc_matrix_multiply_rpmsg/cm4



The main_core1.c file contains two functions:

- The **main()** function contains the code for the target board and eRPC server initialization. After the initialization, the matrix multiply service is added and the eRPC server waits for client's requests in the while loop.
- The **erpcMatrixMultiply()** function is the user implementation of the eRPC function defined in the IDL file.
- There is the possibility to write the application-specific eRPC error handler. The eRPC error handler of the matrix multiply application is implemented in the erpc_error_handler.h and erpc_error_handler.cpp files.

The eRPC-relevant code is captured in the following code snippet:

```
/* erpcMatrixMultiply function user implementation */
void erpcMatrixMultiply(const Matrix *matrix1, const Matrix *matrix2, Matrix *result_matrix)
{
  ...
}
int main()
{
  ...
  /* RPMsg-Lite transport layer initialization */
  erpc_transport_t transport;
  transport = erpc_transport_rpmsg_lite_remote_init(src, dst, (void*)startupData,
  ERPC_TRANSPORT_RPMSG_LITE_LINK_ID, SignalReady, NULL);
  ...
  /* MessageBufferFactory initialization */
  erpc_mbf_t message_buffer_factory;
  message_buffer_factory = erpc_mbf_rpmsg_init(transport);
  ...
  /* eRPC server side initialization */
  erpc_server_t server;
  server = erpc_server_init(transport, message_buffer_factory);
  ...
  /* Adding the service to the server */
  erpc_service_t service = create_MatrixMultiplyService_service();
  erpc_add_service_to_server(server, service);
  ...
  while (1)
  {
    /* Process eRPC requests */
    erpc_status_t status = erpc_server_poll(server);
    /* handle error status */
    if (status != kErpcStatus_Success)
    {
      /* print error description */
      erpc_error_handler(status, 0);
      ...
    }
    ...
  }
}
```

Except for the application main file, there are configuration files for the RPMsg-Lite (rpmsg_config.h) and eRPC (erpc_config.h), located in the *<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_examples/erpc_matrix_multiply_rpmsg* folder.

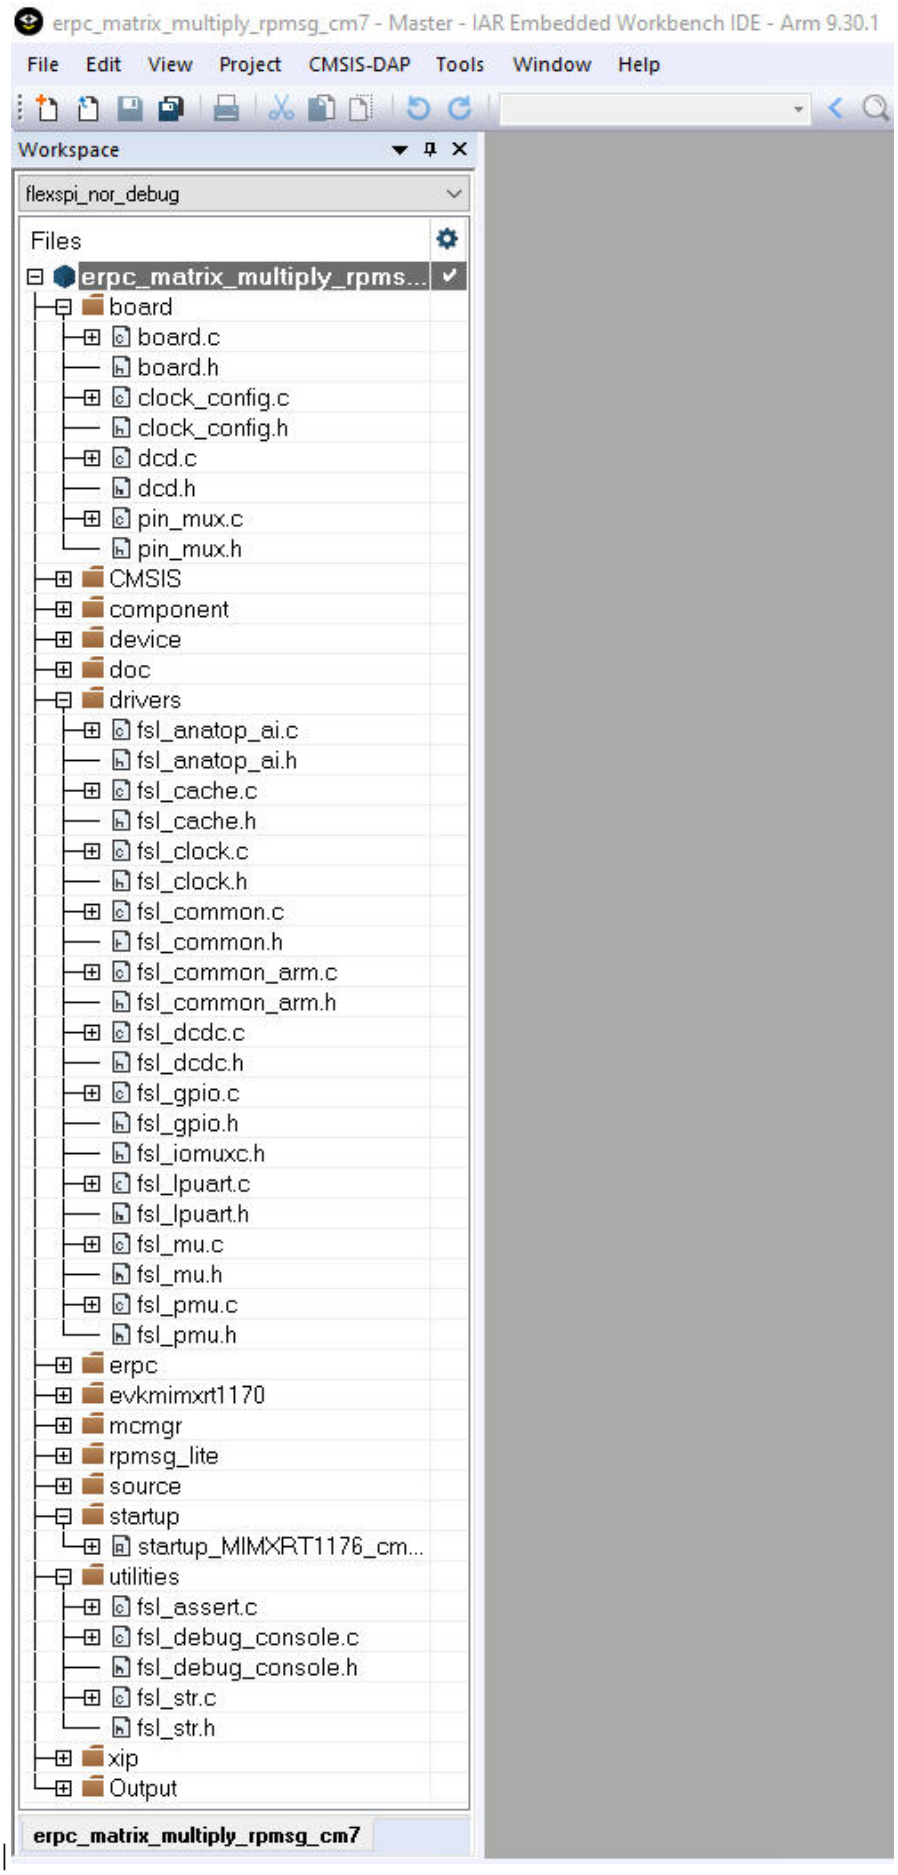
Parent topic: Multicore server application

Parent topic:*Create an eRPC application*

Multicore client application

The “Matrix multiply” eRPC client project is located in the following folder:

<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_examples/erpc_matrix_multiply_rpmsg/cm7/iar



Project files for the eRPC client have the _cm7 suffix.

Client project basic source files

The startup files, board-related settings, peripheral drivers, and utilities belong to the basic project source files and form the skeleton of all MCUXpresso SDK applications. These source files are located in the following folders:

- *<MCUXpressoSDK_install_dir>/devices/<device>*

- *<MCUXpressoSDK_install_dir>/boards/<board_name>/multicore_examples/<example_name>/*

Parent topic: Multicore client application

Client-related generated files

The client-related generated files are:

- erpc_matric_multiply.h
- erpc_matrix_multiply_client.cpp

These files contain the shim code for the functions and data types declared in the IDL file. These functions also call methods for codec initialization, data serialization, performing eRPC requests, and de-serializing outputs into expected data structures (if return values are expected). These shim code files can be found in the *<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_examples/erpc_common/erpc_matrix_multiply/service/* folder.

Parent topic: Multicore client application

Client infrastructure files

The eRPC infrastructure files are located in the following folder:

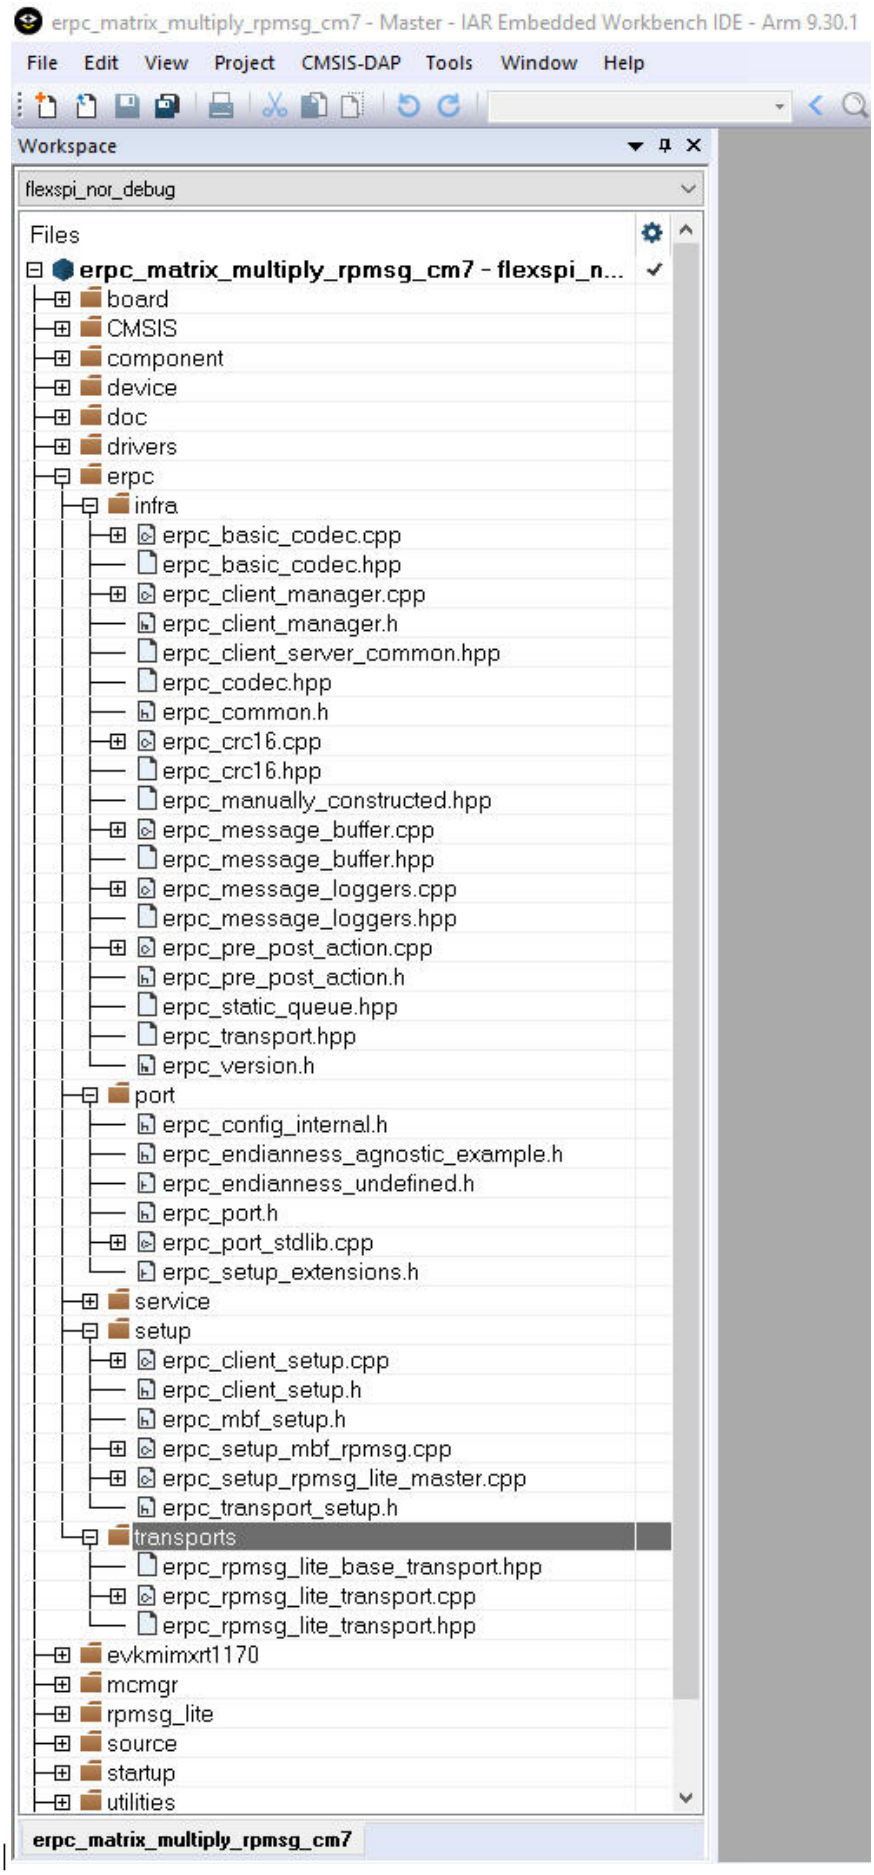
<MCUXpressoSDK_install_dir>/middleware/multicore/erpc/erpc_c

The **erpc_c** folder contains files for creating eRPC client and server applications in the C/C++ language. These files are distributed into subfolders.

- The **infra** subfolder contains C++ infrastructure code used to build server and client applications.

- Two files, erpc_client_manager.h and erpc_client_manager.cpp, are used for managing the client-side application. The main purpose of the client files is to create, perform, and release eRPC requests.
- Three files (erpc_codec.hpp, erpc_basic_codec.hpp, and erpc_basic_codec.cpp) are used for codecs. Currently, the basic codec is the initial and only implementation of the codecs.
- erpc_common.h file is used for common eRPC definitions, typedefs, and enums.
- erpc_manually_constructed.hpp file is used for allocating static storage for the used objects.
- Message buffer files are used for storing serialized data: erpc_message_buffer.hpp and erpc_message_buffer.cpp.
- erpc_transport.hpp file defines the abstract interface for transport layer.

The **port** subfolder contains the eRPC porting layer to adapt to different environments.



- erpc_port.h file contains definition of erpc_malloc() and erpc_free() functions.
- erpc_port_stdlib.cpp file ensures adaptation to stdlib.
- erpc_config_internal.h internal eRPC configuration file.

The **setup** subfolder contains a set of plain C APIs that wrap the C++ infrastructure, providing client and server init and deinit routines that greatly simplify eRPC usage in C-based projects. No knowledge of C++ is required to use these APIs.

- erpc_client_setup.h and erpc_client_setup.cpp files needs to be added into the "Matrix multiply" example project to demonstrate the use of C-wrapped functions in this example.
- erpc_transport_setup.h and erpc_setup_rpmsg_lite_master.cpp files needs to be added into the project in order to allow C-wrapped function for transport layer setup.
- erpc_mbf_setup.h and erpc_setup_mbf_rpmsg.cpp files needs to be added into the project in order to allow message buffer factory usage.

The **transports** subfolder contains transport classes for the different methods of communication supported by eRPC. Some transports are applicable only to host PCs, while others are applicable only to embedded or multicore systems. Most transports have corresponding client and server setup functions, in the setup folder.

- RPMsg-Lite is used as the transport layer for the communication between cores, erpc_rpmsg_lite_base_transport.hpp, erpc_rpmsg_lite_transport.hpp, and erpc_rpmsg_lite_transport.cpp files needs to be added into the client project.

Parent topic: Multicore client application

Client user code

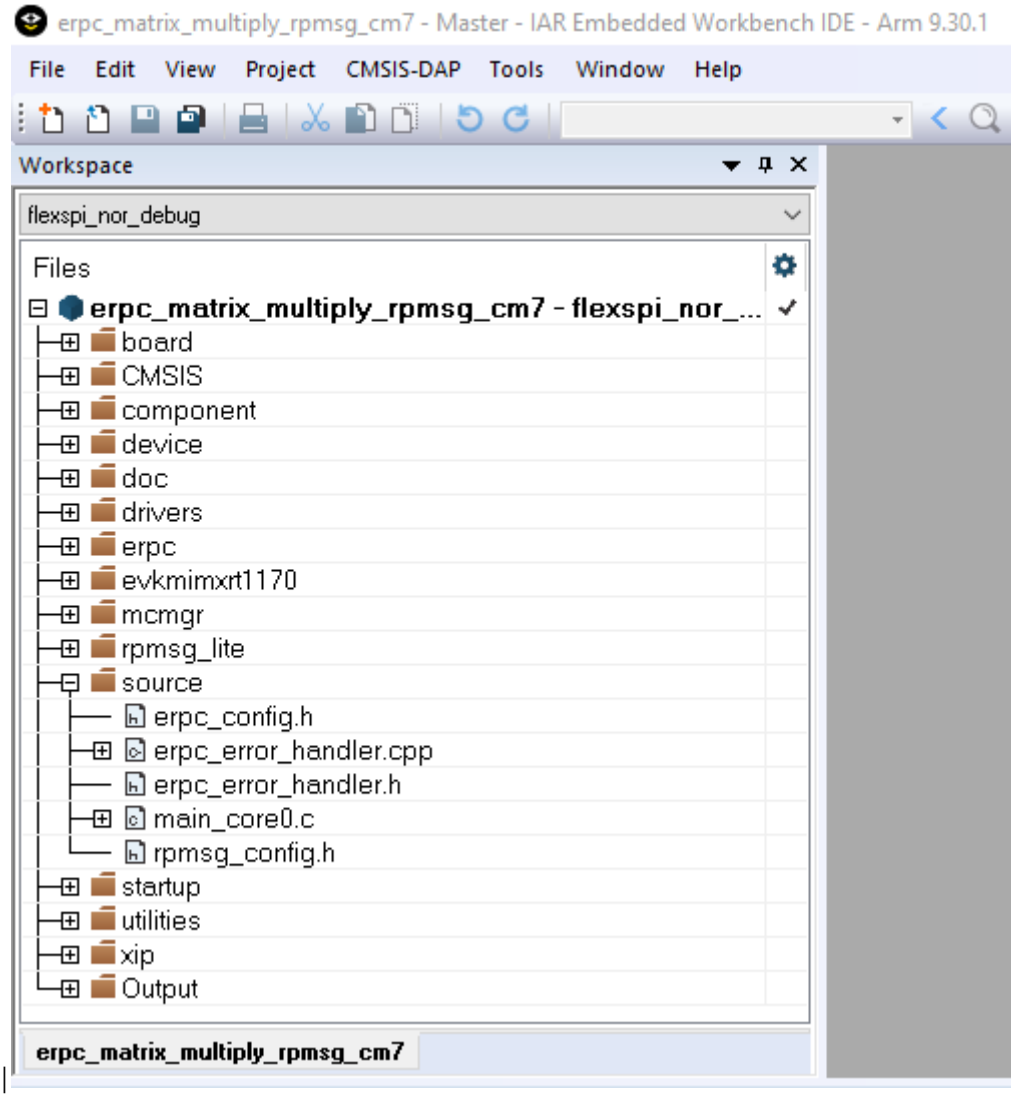
The client's user code is stored in the main_core0.c file, located in the following folder:

<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_example/erpc_matrix_multiply_rpmsg/cm7

The main_core0.c file contains the code for target board and eRPC initialization.

- After initialization, the secondary core is released from reset.
- When the secondary core is ready, the primary core initializes two matrix variables.
- The erpcMatrixMultiply eRPC function is called to issue the eRPC request and get the result.

It is possible to write the application-specific eRPC error handler. The eRPC error handler of the matrix multiply application is implemented in erpc_error_handler.h and erpc_error_handler.cpp files.



The matrix multiplication can be issued repeatedly, when pressing a software board button.

The eRPC-relevant code is captured in the following code snippet:

```
...
extern bool g_erpc_error_occurred;
...
/* Declare matrix arrays */
Matrix matrix1 = {0}, matrix2 = {0}, result_matrix = {0};
...
/* RPMsg-Lite transport layer initialization */
erpc_transport_t transport;
transport = erpc_transport_rpmsg_lite_master_init(src, dst,
ERPC_TRANSPORT_RPMSG_LITE_LINK_ID);
...
/* MessageBufferFactory initialization */
erpc_mbf_t message_buffer_factory;
message_buffer_factory = erpc_mbf_rpmsg_init(transport);
...
/* eRPC client side initialization */
erpc_client_t client;
client = erpc_client_init(transport, message_buffer_factory);
...
/* Set default error handler */
erpc_client_set_error_handler(client, erpc_error_handler);
...
while (1)
{
  /* Invoke the erpcMatrixMultiply function */
  erpcMatrixMultiply(matrix1, matrix2, result_matrix);
  ...
  /* Check if some error occured in eRPC */
  if (g_erpc_error_occurred)
  {
    /* Exit program loop */
    break;
  }
  ...
}
```

Except for the application main file, there are configuration files for the RPMsg-Lite (rpmsg_config.h) and eRPC (erpc_config.h), located in the following folder:

<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_examples/erpc_matrix_multiply_rpmsg

Parent topic: Multicore client application

Parent topic:*Create an eRPC application*

Multiprocessor server application

The “Matrix multiply” eRPC server project for multiprocessor applications is located in the *<MCUXpressoSDK_install_dir»/boards/<board_name>/multiprocessor_examples/erpc_server_matrix_multiply_<transport_layer>* folder.

Most of the multiprocessor application setup is the same as for the multicore application. The multiprocessor server application requires server-related generated files (server shim code), server infrastructure files, and the server user code. There is no need for server multicore infrastructure files (MCMGR and RPMsg-Lite). The RPMsg-Lite transport layer is replaced either by SPI or UART transports. The following table shows the required transport-related files per each transport type.

|SPI|<eRPC base directory>/erpc_c/setup/erpc_setup_(d)spi_slave.cpp

<eRPC base directory>/erpc_c/transports/erpc_(d)spi_slave_transport.hpp

<eRPC base directory>/erpc_c/transports/erpc_(d)spi_slave_transport.cpp

| |UART|<eRPC base directory>/erpc_c/setup/erpc_setup_uart_cmsis.cpp

<eRPC base directory>/erpc_c/transports/erpc_uart_cmsis_transport.hpp

<eRPC base directory>/erpc_c/transports/erpc_uart_cmsis_transport.cpp

|

Server user code

The server's user code is stored in the main_server.c file, located in the *<MCUXpressoSDK_install_dir>/boards/<board_name>/multiprocessor_examples/erpc_server_matrix_multiply_<transport_lay* folder.

The eRPC-relevant code with UART as a transport is captured in the following code snippet:

```
/* erpcMatrixMultiply function user implementation */
void erpcMatrixMultiply(Matrix matrix1, Matrix matrix2, Matrix result_matrix)
{
  ...
}
int main()
{
  ...
  /* UART transport layer initialization, ERPC_DEMO_UART is the structure of CMSIS UART driver␣
↪operations */
  erpc_transport_t transport;
  transport = erpc_transport_cmsis_uart_init((void *)&ERPC_DEMO_UART);
  ...
  /* MessageBufferFactory initialization */
  erpc_mbf_t message_buffer_factory;
  message_buffer_factory = erpc_mbf_dynamic_init();
  ...
  /* eRPC server side initialization */
  erpc_server_t server;
  server = erpc_server_init(transport, message_buffer_factory);
  ...
  /* Adding the service to the server */
  erpc_service_t service = create_MatrixMultiplyService_service();
  erpc_add_service_to_server(server, service);
  ...
  while (1)
  {
    /* Process eRPC requests */
    erpc_status_t status = erpc_server_poll(server)
    /* handle error status */
    if (status != kErpcStatus_Success)
    {
      /* print error description */
      erpc_error_handler(status, 0);
      ...
    }
    ...
  }
}
```

Parent topic: Multiprocessor server application

Multiprocessor client application

The "Matrix multiply" eRPC client project for multiprocessor applications is located in the *<MCUXpressoSDK_install_dir>/boards/<board_name>/multiprocessor_examples/erpc_client_matrix_multiply_<tr* folder.

Most of the multiprocessor application setup is the same as for the multicore application. The multiprocessor server application requires client-related generated files (server shim code),

client infrastructure files, and the client user code. There is no need for client multicore infrastructure files (MCMGR and RPMsg-Lite). The RPMsg-Lite transport layer is replaced either by SPI or UART transports. The following table shows the required transport-related files per each transport type.

|SPI|<eRPC base directory>/erpc_c/setup/erpc_setup_(d)spi_master.cpp

<eRPC base directory>/erpc_c/transports/ erpc_(d)spi_master_transport.hpp

<eRPC base directory>/erpc_c/transports/ erpc_(d)spi_master_transport.cpp

| |UART|<eRPC base directory>/erpc_c/setup/erpc_setup_uart_cmsis.cpp

<eRPC base directory>/erpc_c/transports/erpc_uart_cmsis_transport.hpp

<eRPC base directory>/erpc_c/transports/erpc_uart_cmsis_transport.cpp

|

Client user code

The client's user code is stored in the main_client.c file, located in the *<MCUXpressoSDK_install_dir>/boards/<board_name>/multiprocessor_examples/erpc_client_matrix_multiply_<transport_layer>/* folder.

The eRPC-relevant code with UART as a transport is captured in the following code snippet:

```
...
extern bool g_erpc_error_occurred;
...
/* Declare matrix arrays */
Matrix matrix1 = {0}, matrix2 = {0}, result_matrix = {0};
...
/* UART transport layer initialization, ERPC_DEMO_UART is the structure of CMSIS UART driver␣
↪operations */
erpc_transport_t transport;
transport = erpc_transport_cmsis_uart_init((void *)&ERPC_DEMO_UART);
...
/* MessageBufferFactory initialization */
erpc_mbf_t message_buffer_factory;
message_buffer_factory = erpc_mbf_dynamic_init();
...
/* eRPC client side initialization */
erpc_client_t client;
client = erpc_client_init(transport,message_buffer_factory);
...
/* Set default error handler */
erpc_client_set_error_handler(client, erpc_error_handler);
...
while (1)
{
  /* Invoke the erpcMatrixMultiply function */
  erpcMatrixMultiply(matrix1, matrix2, result_matrix);
  ...
  /* Check if some error occured in eRPC */
  if (g_erpc_error_occurred)
  {
    /* Exit program loop */
    break;
  }
  ...
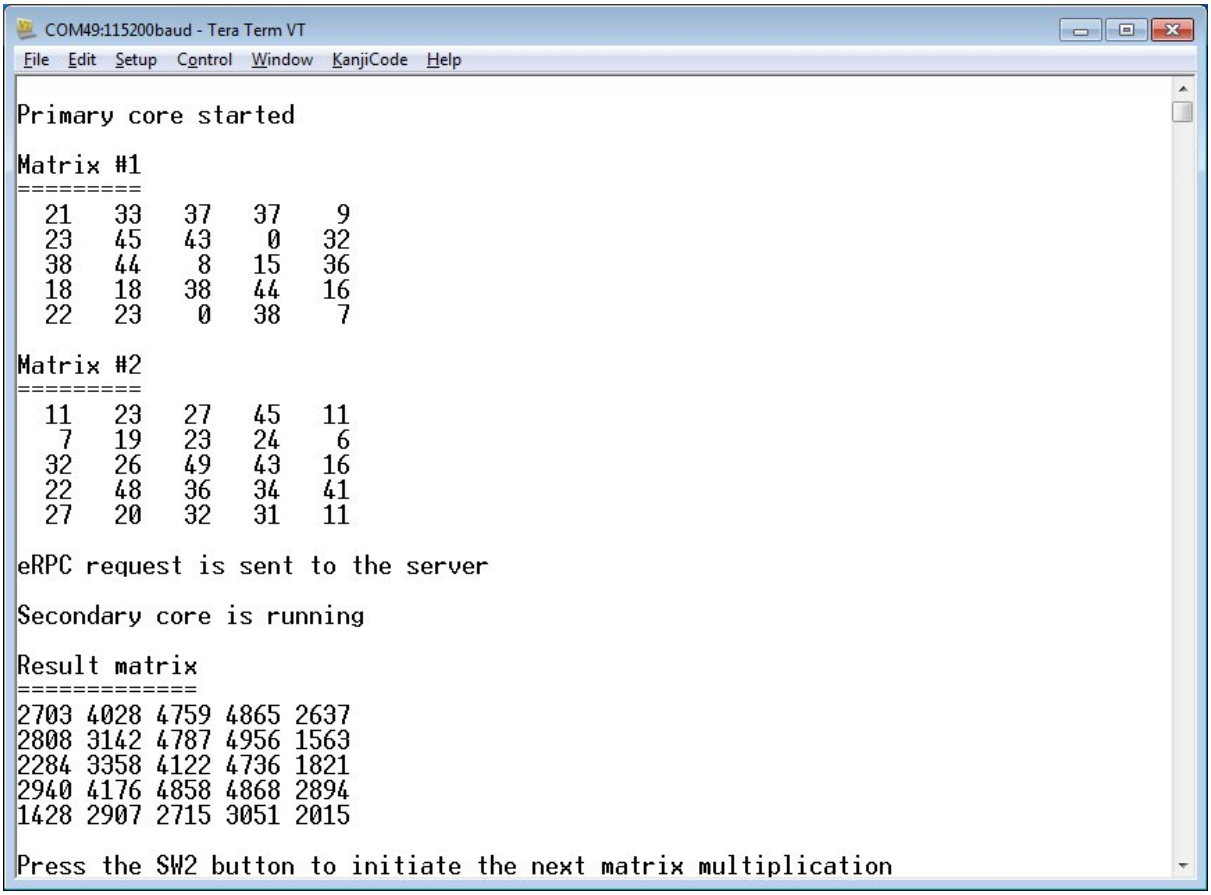
}
```



Parent topic: Multiprocessor client application

Parent topic: Multiprocessor server application

Parent topic:*Create an eRPC application*

Running the eRPC application

Follow the instructions in *Getting Started with MCUXpresso SDK* (document MCUXSDKGSUG) (located in the <*MCUXpressoSDK_install_dir*>/*docs* folder), to load both the primary and the secondary core images into the on-chip memory, and then effectively debug the dual-core application. After the application is running, the serial console should look like:

For multiprocessor applications that are running between PC and the target evaluation board or between two boards, follow the instructions in the accompanied example readme files that provide details about the proper board setup and the PC side setup (Python).

Parent topic:*Create an eRPC application*

Parent topic:*eRPC example*

eRPC example

This section shows how to create an example eRPC application called “Matrix multiply”, which implements one eRPC function (matrix multiply) with two function parameters (two matrices). The client-side application calls this eRPC function, and the server side performs the multiplication of received matrices. The server side then returns the result.

For example, use the NXP MIMXRT1170-EVK board as the target dual-core platform, and the IAR Embedded Workbench for ARM (EWARM) as the target IDE for developing the eRPC example.

- The primary core (CM7) runs the eRPC client.
- The secondary core (CM4) runs the eRPC server.
- RPMsg-Lite (Remote Processor Messaging Lite) is used as the eRPC transport layer.

The “Matrix multiply” application can be also run in the multi-processor setup. In other words, the eRPC client running on one SoC comunicates with the eRPC server that runs on anothe SoC, utilizing different transport channels. It is possible to run the board-to-PC example (PC as the eRPC server and a board as the eRPC client, and vice versa) and also the board-to-board example. These multiprocessor examples are prepared for selected boards only.

|Multicore application source and project files|*<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore*
|Multiprocessor application source and project files|*<MCUXpressoSDK_install_dir>/boards/<board_name>/multi*

<MCUXpressoSDK_install_dir>/boards/<board_name>/multiprocessor_examples/erpc_server_matrix_multiply_<tr

| |eRPC source files|*<MCUXpressoSDK_install_dir>/middleware/multicore/erpc/*| |RPMsg-Lite source files|*<MCUXpressoSDK_install_dir>/middleware/multicore/rpmsg_lite/*|

Designing the eRPC application

The matrix multiply application is based on calling single eRPC function that takes 2 two-dimensional arrays as input and returns matrix multiplication results as another 2 two-dimensional array. The IDL file syntax supports arrays with the dimension length set by the number only (in the current eRPC implementation). Because of this, a variable is declared in the IDL dedicated to store information about matrix dimension length, and to allow easy maintenance of the user and server code.

For a simple use of the two-dimensional array, the alias name (new type definition) for this data type has is declared in the IDL. Declaring this alias name ensures that the same data type can be used across the client and server applications.

Parent topic:*eRPC example*

Creating the IDL file

The created IDL file is located in the following folder:

<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_examples/erpc_common/erpc_matrix_multiply/s

The created IDL file contains the following code:

```
program erpc_matrix_multiply
/*! This const defines the matrix size. The value has to be the same as the
Matrix array dimension. Do not forget to re-generate the erpc code once the
matrix size is changed in the erpc file */
const int32 matrix_size = 5;
/*! This is the matrix array type. The dimension has to be the same as the
matrix size const. Do not forget to re-generate the erpc code once the
matrix size is changed in the erpc file */
type Matrix = int32[matrix_size][matrix_size];
interface MatrixMultiplyService {
erpcMatrixMultiply(in Matrix matrix1, in Matrix matrix2, out Matrix result_matrix) ->
void
}
```

Details:

- The IDL file starts with the program name (*erpc_matrix_multiply*), and this program name is used in the naming of all generated outputs.
- The declaration and definition of the constant variable named *matrix_size* follows next. The *matrix_size* variable is used for passing information about the length of matrix dimensions to the client/server user code.
- The alias name for the two-dimensional array type (*Matrix*) is declared.
- The interface group *MatrixMultiplyService* is located at the end of the IDL file. This interface group contains only one function declaration *erpcMatrixMultiply*.

- As shown above, the function's declaration contains three parameters of Matrix type: *matrix1* and *matrix2* are input parameters, while *result_matrix* is the output parameter. Additionally, the returned data type is declared as void.

When writing the IDL file, the following order of items is recommended:

1. Program name at the top of the IDL file.
2. New data types and constants declarations.
3. Declarations of interfaces and functions at the end of the IDL file.

Parent topic:*eRPC example*

Using the eRPC generator tool

|Windows OS|<MCUXpressoSDK_install_dir>/middleware/multicore/tools/erpcgen/Windows|
|Linux OS|<MCUXpressoSDK_install_dir>/middleware/multicore/tools/erpcgen/Linux_x64

<MCUXpressoSDK_install_dir>/middleware/multicore/tools/erpcgen/Linux_x86

| |Mac OS|<MCUXpressoSDK_install_dir>/middleware/multicore/tools/erpcgen/Mac|

The files for the "Matrix multiply" example are pre-generated and already a part of the application projects. The following section describes how they have been created.

- The easiest way to create the shim code is to copy the erpcgen application to the same folder where the IDL file (*.erpc) is located; then run the following command:

  erpcgen <IDL_file>.erpc

- In the "Matrix multiply" example, the command should look like:

  erpcgen erpc_matrix_multiply.erpc

Additionally, another method to create the shim code is to execute the eRPC application using input commands:

- "-?"/"—help" – Shows supported commands.
- "-o <filePath>"/"—output<filePath>" – Sets the output directory.

For example,

```
<path_to_erpcgen>/erpcgen –o <path_to_output>
<path_to_IDL>/<IDL_file_name>.erpc
```

For the "Matrix multiply" example, when the command is executed from the default erpcgen location, it looks like:

erpcgen –o

../../../../../boards/evkmimxrt1170/multicore_examples/erpc_common/erpc_matrix_multiply/service
../../../../../boards/evkmimxrt1170/multicore_examples/erpc_common/erpc_matrix_multiply/service/erpc_matrix_mu

In both cases, the following four files are generated into the *<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_examples/erpc_common/erpc_matrix_multiply/service folder.*

- erpc_matrix_multiply.h
- erpc_matrix_multiply_client.cpp
- erpc_matrix_multiply_server.h
- erpc_matrix_multiply_server.cpp

For multiprocessor examples, the eRPC file and pre-generated files can be found in the *<MCUXpressoSDK_install_dir>/boards/<board_name>/multiprocessor_examples/erpc_common/erpc_matrix_multiply/serv* folder.

For Linux OS users:

- Do not forget to set the permissions for the eRPC generator application.
- Run the application as ./erpcgen... instead of as erpcgen ....

Parent topic:*eRPC example*

Create an eRPC application

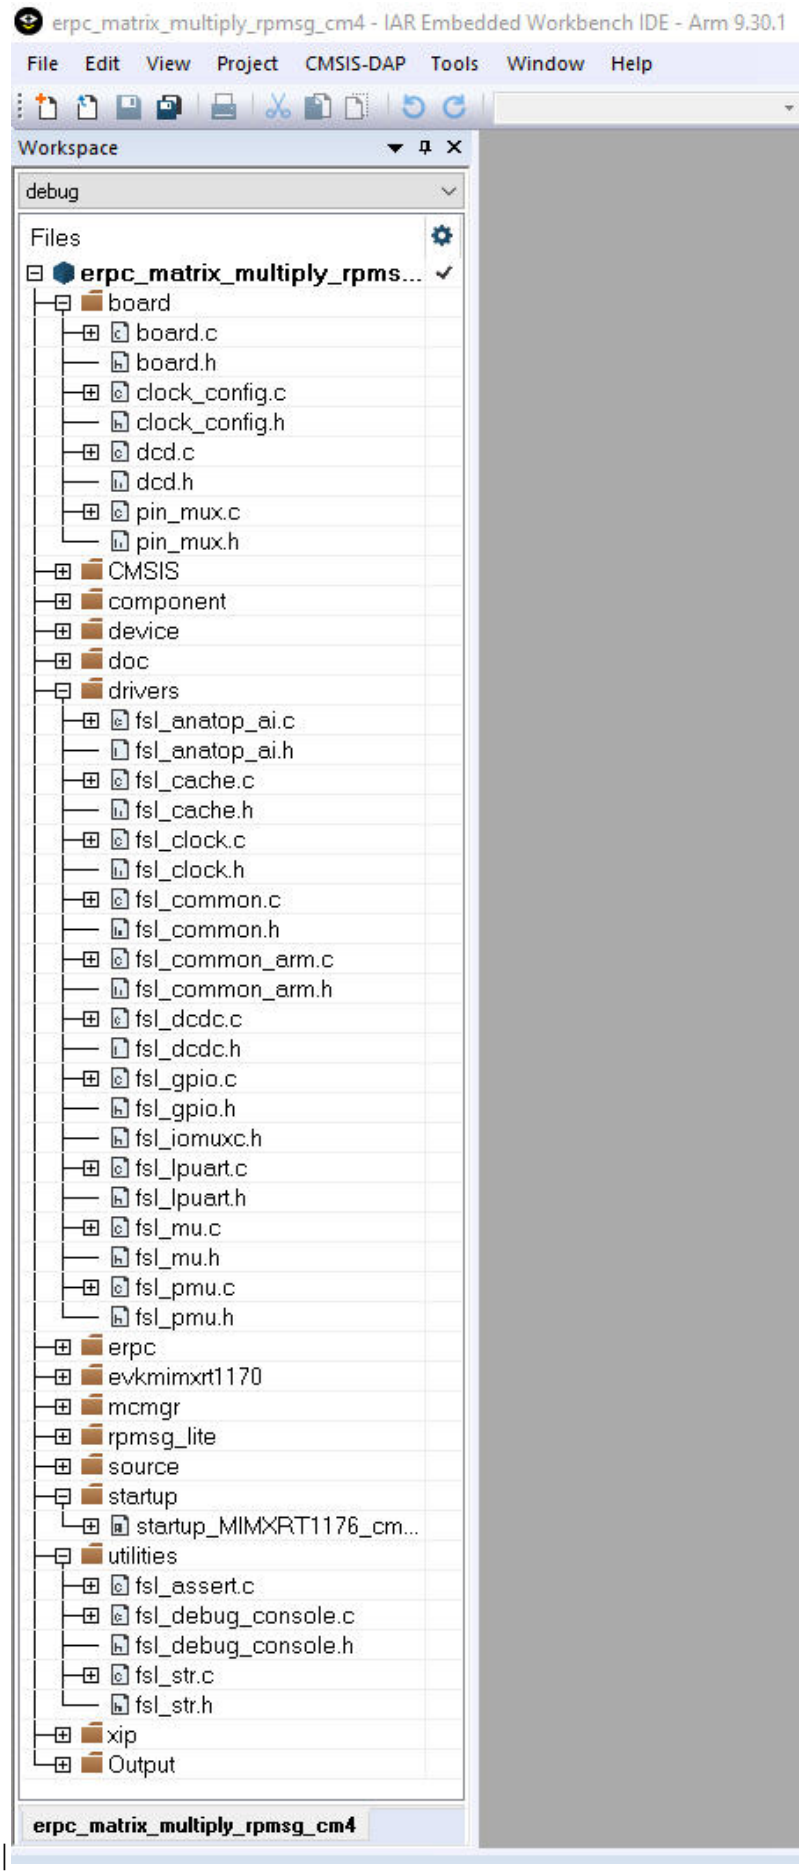
This section describes a generic way to create a client/server eRPC application:

1. **Design the eRPC application:** Decide which data types are sent between applications, and define functions that send/receive this data.
2. **Create the IDL file:** The IDL file contains information about data types and functions used in an eRPC application, and is written in the IDL language.
3. **Use the eRPC generator tool:** This tool takes an IDL file and generates the shim code for the client and the server-side applications.
4. **Create an eRPC application:**
    1. Create two projects, where one project is for the client side (primary core) and the other project is for the server side (secondary core).
    2. Add generated files for the client application to the client project, and add generated files for the server application to the server project.
    3. Add infrastructure files.
    4. Add user code for client and server applications.
    5. Set the client and server project options.
5. **Run the eRPC application:** Run both the server and the client applications. Make sure that the server has been run before the client request was sent.

A specific example follows in the next section.

Multicore server application

The “Matrix multiply” eRPC server project is located in the following folder:



<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_examples/erpc_matrix_multiply_rpmsg/cm4/iar

The project files for the eRPC server have the _cm4 suffix.

Server project basic source files

The startup files, board-related settings, peripheral drivers, and utilities belong to the basic project source files and form the skeleton of all MCUXpresso SDK applications. These source files are located in:

- *<MCUXpressoSDK_install_dir>/devices/<device>*
- *<MCUXpressoSDK_install_dir>/boards/<board_name>/multicore_examples/<example_name>/*

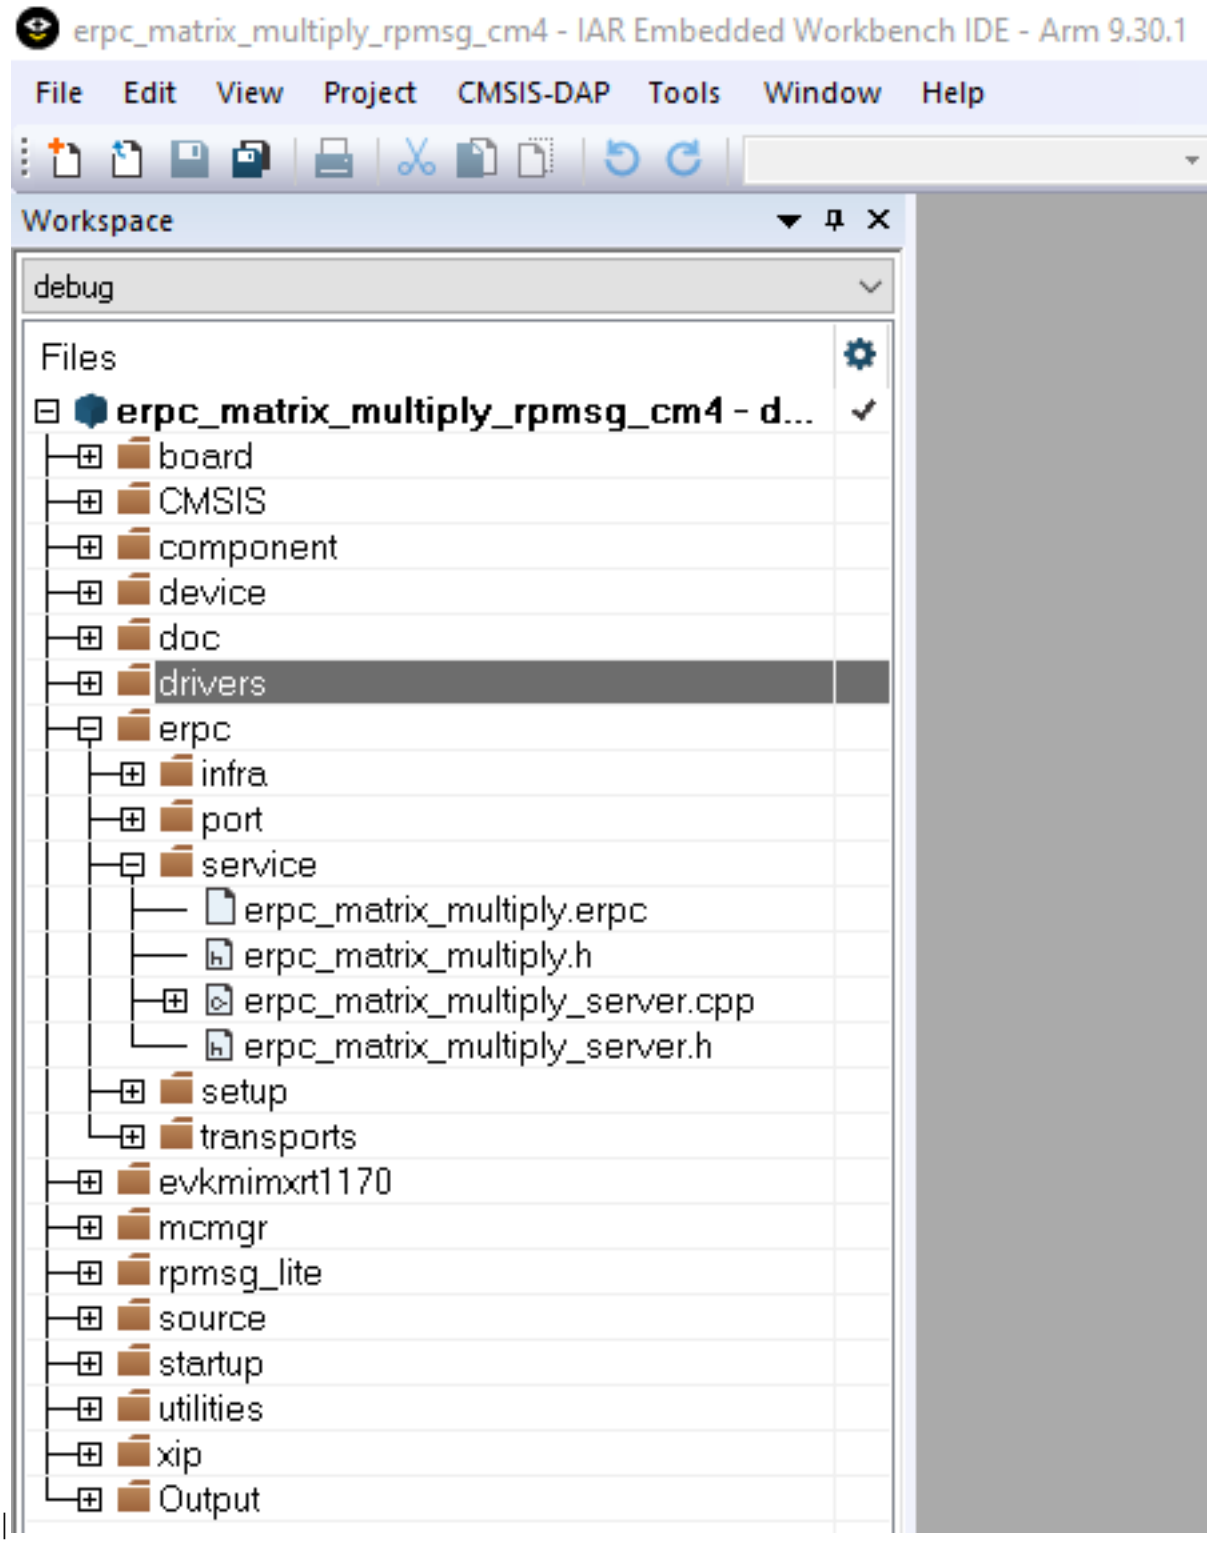
Parent topic: Multicore server application



Server related generated files

The server-related generated files are:

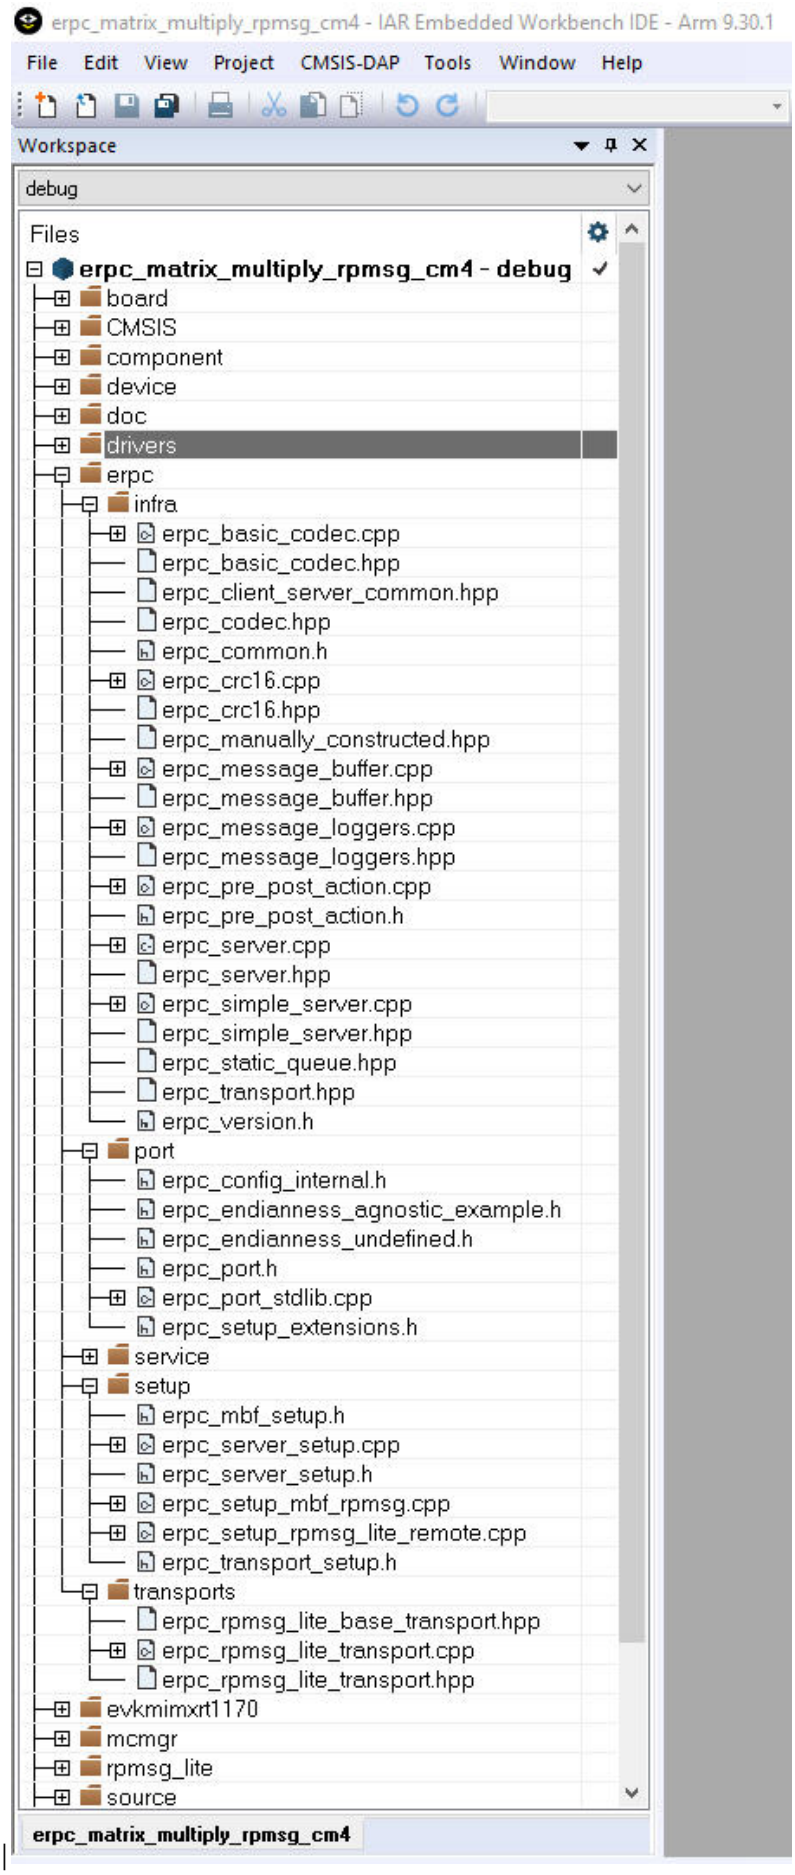
- erpc_matric_multiply.h
- erpc_matrix_multiply_server.h
- erpc_matrix_multiply_server.cpp

The server-related generated files contain the shim code for functions and data types declared in the IDL file. These files also contain functions for the identification of client requested functions, data deserialization, calling requested function's implementations, and data serialization and return, if requested by the client. These shim code files can be found in the following folder:

<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_examples/erpc_common/erpc_matrix_multiply/s

Parent topic: Multicore server application

Server infrastructure files



The eRPC infrastructure files are located in the following folder:

<MCUXpressoSDK_install_dir>/middleware/multicore/erpc/erpc_c

The **erpc_c** folder contains files for creating eRPC client and server applications in the *C/C++*

language. These files are distributed into subfolders.

- The **infra** subfolder contains C++ infrastructure code used to build server and client applications.
  - Four files, erpc_server.hpp, erpc_server.cpp, erpc_simple_server.hpp, and erpc_simple_server.cpp, are used for running the eRPC server on the server-side applications. The simple server is currently the only implementation of the server, and its role is to catch client requests, identify and call requested functions, and send data back when requested.
  - Three files (erpc_codec.hpp, erpc_basic_codec.hpp, and erpc_basic_codec.cpp) are used for codecs. Currently, the basic codec is the initial and only implementation of the codecs.
  - The erpc_common.hpp file is used for common eRPC definitions, typedefs, and enums.
  - The erpc_manually_constructed.hpp file is used for allocating static storage for the used objects.
  - Message buffer files are used for storing serialized data: erpc_message_buffer.h and erpc_message_buffer.cpp.
  - The erpc_transport.h file defines the abstract interface for transport layer.
- The **port** subfolder contains the eRPC porting layer to adapt to different environments.
  - erpc_port.h file contains definition of erpc_malloc() and erpc_free() functions.
  - erpc_port_stdlib.cpp file ensures adaptation to stdlib.
  - erpc_config_internal.h internal erpc configuration file.
- The **setup** subfolder contains a set of plain C APIs that wrap the C++ infrastructure, providing client and server init and deinit routines that greatly simplify eRPC usage in C-based projects. No knowledge of C++ is required to use these APIs.
  - The erpc_server_setup.h and erpc_server_setup.cpp files needs to be added into the "Matrix multiply" example project to demonstrate the use of C-wrapped functions in this example.
  - The erpc_transport_setup.h and erpc_setup_rpmsg_lite_remote.cpp files needs to be added into the project in order to allow the C-wrapped function for transport layer setup.
  - The erpc_mbf_setup.h and erpc_setup_mbf_rpmsg.cpp files needs to be added into the project in order to allow message buffer factory usage.
- The **transports** subfolder contains transport classes for the different methods of communication supported by eRPC. Some transports are applicable only to host PCs, while others are applicable only to embedded or multicore systems. Most transports have corresponding client and server setup functions in the setup folder.
  - RPMsg-Lite is used as the transport layer for the communication between cores, erpc_rpmsg_lite_base_transport.hpp, erpc_rpmsg_lite_transport.hpp, and erpc_rpmsg_lite_transport.cpp files need to be added into the server project.

Parent topic: Multicore server application

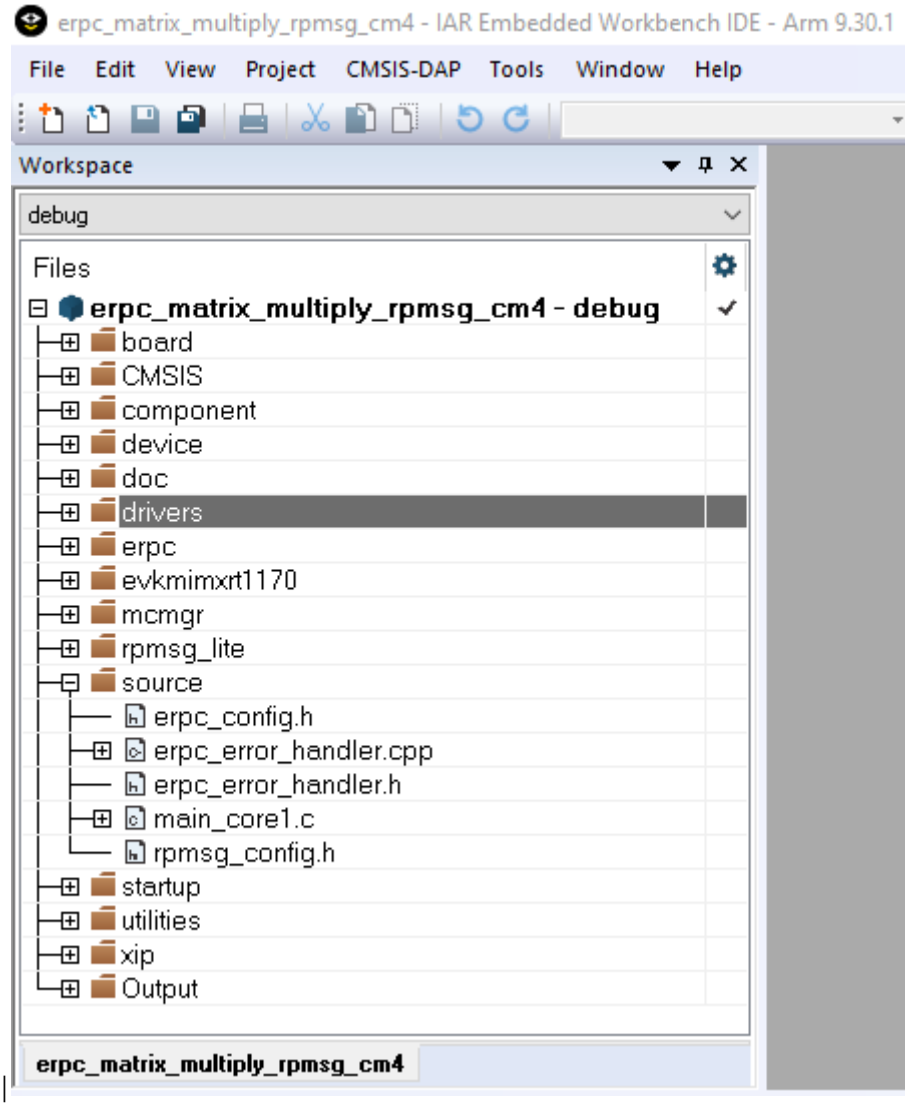
Server user code

The server's user code is stored in the main_core1.c file, located in the following folder:

<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_examples/erpc_matrix_multiply_rpmsg/cm4



The main_core1.c file contains two functions:

- The **main()** function contains the code for the target board and eRPC server initialization. After the initialization, the matrix multiply service is added and the eRPC server waits for client's requests in the while loop.
- The **erpcMatrixMultiply()** function is the user implementation of the eRPC function defined in the IDL file.
- There is the possibility to write the application-specific eRPC error handler. The eRPC error handler of the matrix multiply application is implemented in the erpc_error_handler.h and erpc_error_handler.cpp files.

The eRPC-relevant code is captured in the following code snippet:

```
/* erpcMatrixMultiply function user implementation */
void erpcMatrixMultiply(const Matrix *matrix1, const Matrix *matrix2, Matrix *result_matrix)
{
  ...
}
int main()
{
  ...
  /* RPMsg-Lite transport layer initialization */
  erpc_transport_t transport;
  transport = erpc_transport_rpmsg_lite_remote_init(src, dst, (void*)startupData,
  ERPC_TRANSPORT_RPMSG_LITE_LINK_ID, SignalReady, NULL);
  ...
  /* MessageBufferFactory initialization */
  erpc_mbf_t message_buffer_factory;
  message_buffer_factory = erpc_mbf_rpmsg_init(transport);
  ...
  /* eRPC server side initialization */
  erpc_server_t server;
  server = erpc_server_init(transport, message_buffer_factory);
  ...
  /* Adding the service to the server */
  erpc_service_t service = create_MatrixMultiplyService_service();
  erpc_add_service_to_server(server, service);
  ...
  while (1)
  {
    /* Process eRPC requests */
    erpc_status_t status = erpc_server_poll(server);
    /* handle error status */
    if (status != kErpcStatus_Success)
    {
      /* print error description */
      erpc_error_handler(status, 0);
      ...
    }
    ...
  }
}
```

Except for the application main file, there are configuration files for the RPMsg-Lite (rpmsg_config.h) and eRPC (erpc_config.h), located in the *<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_examples/erpc_matrix_multiply_rpmsg* folder.

Parent topic: Multicore client application

Client-related generated files

The client-related generated files are:

- erpc_matric_multiply.h
- erpc_matrix_multiply_client.cpp

These files contain the shim code for the functions and data types declared in the IDL file. These functions also call methods for codec initialization, data serialization, performing eRPC requests, and de-serializing outputs into expected data structures (if return values are expected). These shim code files can be found in the *<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_examples/erpc_common/erpc_matrix_multiply/service/* folder.

Parent topic: Multicore client application

Client infrastructure files

The eRPC infrastructure files are located in the following folder:

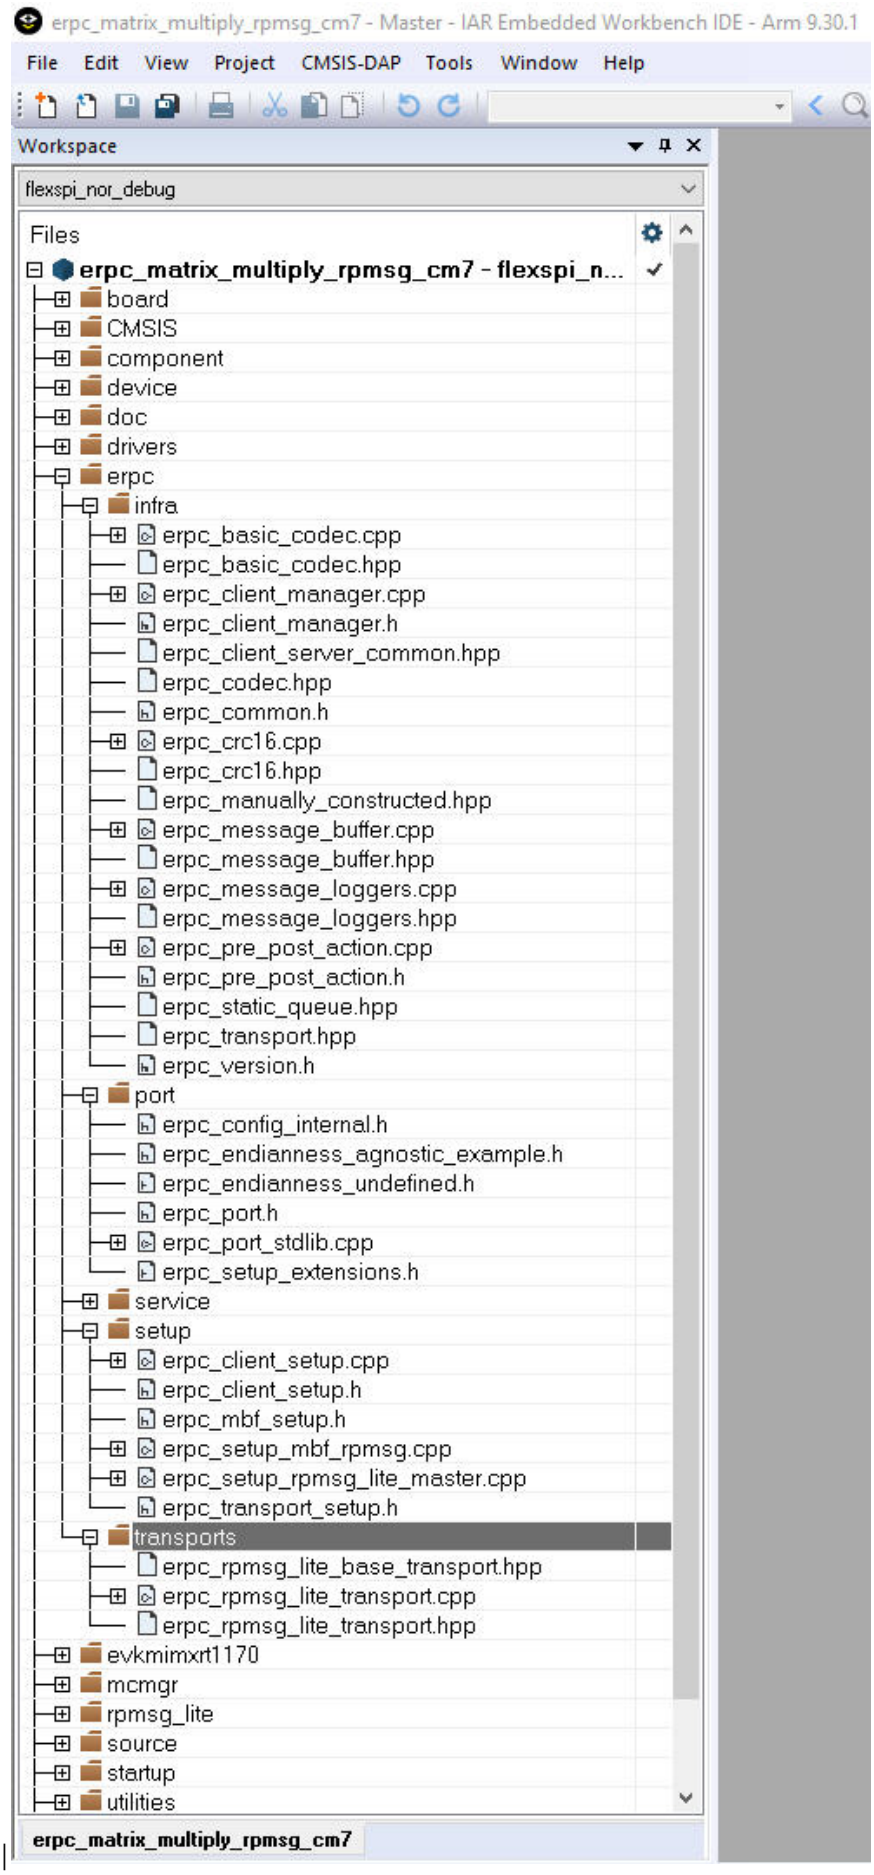
<MCUXpressoSDK_install_dir>/middleware/multicore/erpc/erpc_c

The **erpc_c** folder contains files for creating eRPC client and server applications in the C/C++ language. These files are distributed into subfolders.

- The **infra** subfolder contains C++ infrastructure code used to build server and client applications.

- Two files, erpc_client_manager.h and erpc_client_manager.cpp, are used for managing the client-side application. The main purpose of the client files is to create, perform, and release eRPC requests.
- Three files (erpc_codec.hpp, erpc_basic_codec.hpp, and erpc_basic_codec.cpp) are used for codecs. Currently, the basic codec is the initial and only implementation of the codecs.
- erpc_common.h file is used for common eRPC definitions, typedefs, and enums.
- erpc_manually_constructed.hpp file is used for allocating static storage for the used objects.
- Message buffer files are used for storing serialized data: erpc_message_buffer.hpp and erpc_message_buffer.cpp.
- erpc_transport.hpp file defines the abstract interface for transport layer.

The **port** subfolder contains the eRPC porting layer to adapt to different environments.



- erpc_port.h file contains definition of erpc_malloc() and erpc_free() functions.
- erpc_port_stdlib.cpp file ensures adaptation to stdlib.
- erpc_config_internal.h internal eRPC configuration file.

The **setup** subfolder contains a set of plain C APIs that wrap the C++ infrastructure, providing client and server init and deinit routines that greatly simplify eRPC usage in C-based projects. No knowledge of C++ is required to use these APIs.

- erpc_client_setup.h and erpc_client_setup.cpp files needs to be added into the "Matrix multiply" example project to demonstrate the use of C-wrapped functions in this example.
- erpc_transport_setup.h and erpc_setup_rpmsg_lite_master.cpp files needs to be added into the project in order to allow C-wrapped function for transport layer setup.
- erpc_mbf_setup.h and erpc_setup_mbf_rpmsg.cpp files needs to be added into the project in order to allow message buffer factory usage.

The **transports** subfolder contains transport classes for the different methods of communication supported by eRPC. Some transports are applicable only to host PCs, while others are applicable only to embedded or multicore systems. Most transports have corresponding client and server setup functions, in the setup folder.

- RPMsg-Lite is used as the transport layer for the communication between cores, erpc_rpmsg_lite_base_transport.hpp, erpc_rpmsg_lite_transport.hpp, and erpc_rpmsg_lite_transport.cpp files needs to be added into the client project.

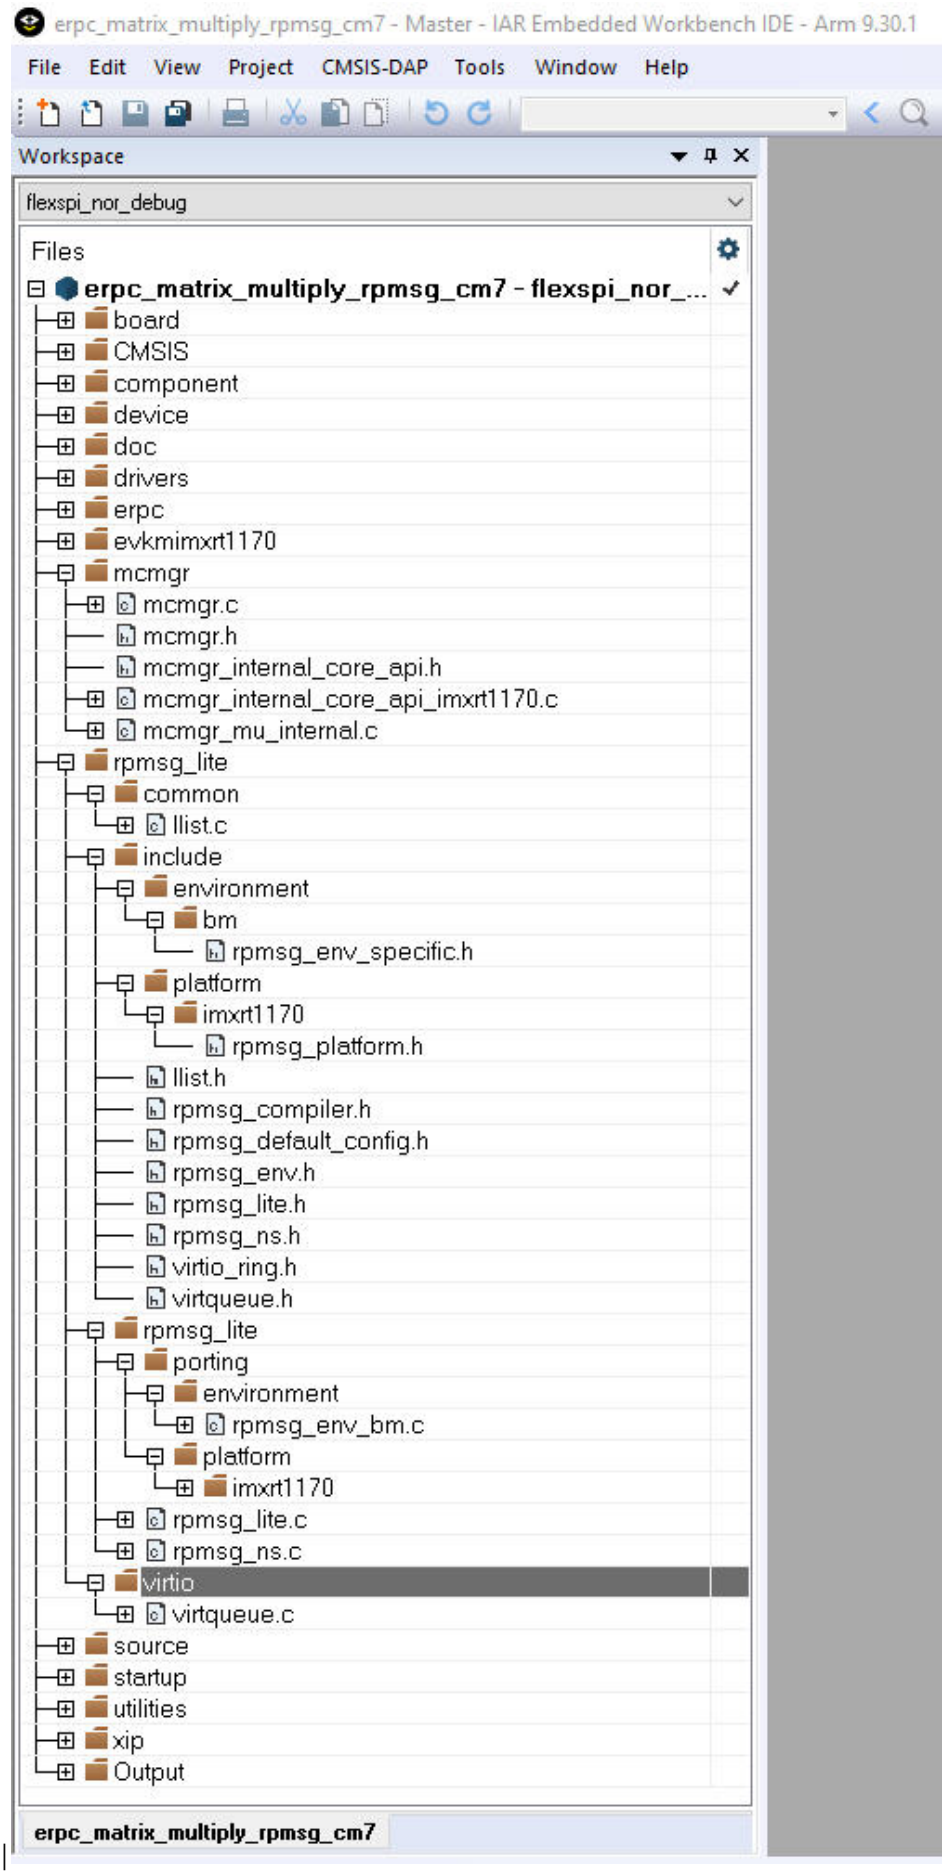
Parent topic: Multicore client application



Client multicore infrastructure files

Because of the RPMsg-Lite (transport layer), it is also necessary to include RPMsg-Lite related files, which are in the following folder:

<MCUXpressoSDK_install_dir>/middleware/multicore/rpmsg_lite/

The multicore example applications also use the Multicore Manager software library to control the secondary core startup and shutdown. These source files are located in the following folder:

<MCUXpressoSDK_install_dir>/middleware/multicore/mcmgr/

Parent topic: Multicore client application

Client user code

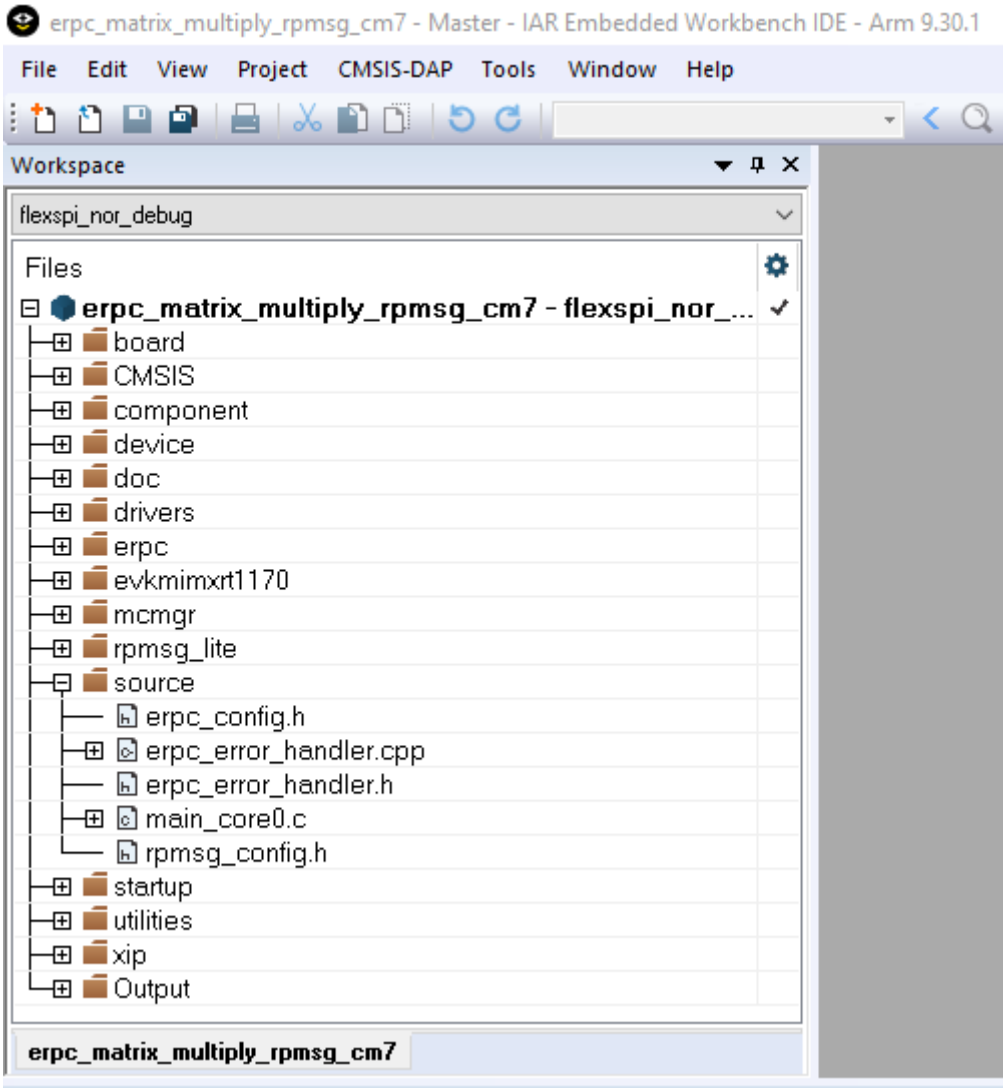
The client's user code is stored in the main_core0.c file, located in the following folder:

<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_example/erpc_matrix_multiply_rpmsg/cm7

The main_core0.c file contains the code for target board and eRPC initialization.

- After initialization, the secondary core is released from reset.
- When the secondary core is ready, the primary core initializes two matrix variables.
- The erpcMatrixMultiply eRPC function is called to issue the eRPC request and get the result.

It is possible to write the application-specific eRPC error handler. The eRPC error handler of the matrix multiply application is implemented in erpc_error_handler.h and erpc_error_handler.cpp files.



The matrix multiplication can be issued repeatedly, when pressing a software board button.

The eRPC-relevant code is captured in the following code snippet:

```
...
extern bool g_erpc_error_occurred;
...
/* Declare matrix arrays */
Matrix matrix1 = {0}, matrix2 = {0}, result_matrix = {0};
...
/* RPMsg-Lite transport layer initialization */
erpc_transport_t transport;
transport = erpc_transport_rpmsg_lite_master_init(src, dst,
ERPC_TRANSPORT_RPMSG_LITE_LINK_ID);
...
/* MessageBufferFactory initialization */
erpc_mbf_t message_buffer_factory;
message_buffer_factory = erpc_mbf_rpmsg_init(transport);
...
/* eRPC client side initialization */
erpc_client_t client;
client = erpc_client_init(transport, message_buffer_factory);
...
/* Set default error handler */
erpc_client_set_error_handler(client, erpc_error_handler);
...
while (1)
{
  /* Invoke the erpcMatrixMultiply function */
  erpcMatrixMultiply(matrix1, matrix2, result_matrix);
  ...
  /* Check if some error occured in eRPC */
  if (g_erpc_error_occurred)
  {
    /* Exit program loop */
    break;
  }
  ...
}
```

Except for the application main file, there are configuration files for the RPMsg-Lite (rpmsg_config.h) and eRPC (erpc_config.h), located in the following folder:

<MCUXpressoSDK_install_dir>/boards/evkmimxrt1170/multicore_examples/erpc_matrix_multiply_rpmsg

Parent topic: Multicore client application

Parent topic:*Create an eRPC application*

Multiprocessor server application

The “Matrix multiply” eRPC server project for multiprocessor applications is located in the *<MCUXpressoSDK_install_dir»/boards/<board_name>/multiprocessor_examples/erpc_server_matrix_multiply_<transport_layer>* folder.

Most of the multiprocessor application setup is the same as for the multicore application. The multiprocessor server application requires server-related generated files (server shim code), server infrastructure files, and the server user code. There is no need for server multicore infrastructure files (MCMGR and RPMsg-Lite). The RPMsg-Lite transport layer is replaced either by SPI or UART transports. The following table shows the required transport-related files per each transport type.

|SPI|<eRPC base directory>/erpc_c/setup/erpc_setup_(d)spi_slave.cpp

<eRPC base directory>/erpc_c/transports/erpc_(d)spi_slave_transport.hpp

<eRPC base directory>/erpc_c/transports/erpc_(d)spi_slave_transport.cpp

| |UART|<eRPC base directory>/erpc_c/setup/erpc_setup_uart_cmsis.cpp

<eRPC base directory>/erpc_c/transports/erpc_uart_cmsis_transport.hpp

<eRPC base directory>/erpc_c/transports/erpc_uart_cmsis_transport.cpp

|

Server user code

The server's user code is stored in the main_server.c file, located in the *<MCUXpressoSDK_install_dir>/boards/<board_name>/multiprocessor_examples/erpc_server_matrix_multiply_<transport_lay* folder.

The eRPC-relevant code with UART as a transport is captured in the following code snippet:

```
/* erpcMatrixMultiply function user implementation */
void erpcMatrixMultiply(Matrix matrix1, Matrix matrix2, Matrix result_matrix)
{
  ...
}
int main()
{
  ...
  /* UART transport layer initialization, ERPC_DEMO_UART is the structure of CMSIS UART driver␣
↪operations */
  erpc_transport_t transport;
  transport = erpc_transport_cmsis_uart_init((void *)&ERPC_DEMO_UART);
  ...
  /* MessageBufferFactory initialization */
  erpc_mbf_t message_buffer_factory;
  message_buffer_factory = erpc_mbf_dynamic_init();
  ...
  /* eRPC server side initialization */
  erpc_server_t server;
  server = erpc_server_init(transport, message_buffer_factory);
  ...
  /* Adding the service to the server */
  erpc_service_t service = create_MatrixMultiplyService_service();
  erpc_add_service_to_server(server, service);
  ...
  while (1)
  {
    /* Process eRPC requests */
    erpc_status_t status = erpc_server_poll(server)
    /* handle error status */
    if (status != kErpcStatus_Success)
    {
      /* print error description */
      erpc_error_handler(status, 0);
      ...
    }
    ...
  }
}
```

Parent topic: Multiprocessor server application

Multiprocessor client application

The "Matrix multiply" eRPC client project for multiprocessor applications is located in the *<MCUXpressoSDK_install_dir>/boards/<board_name>/multiprocessor_examples/erpc_client_matrix_multiply_<tr* folder.

Most of the multiprocessor application setup is the same as for the multicore application. The multiprocessor server application requires client-related generated files (server shim code),

client infrastructure files, and the client user code. There is no need for client multicore infrastructure files (MCMGR and RPMsg-Lite). The RPMsg-Lite transport layer is replaced either by SPI or UART transports. The following table shows the required transport-related files per each transport type.

|SPI|<eRPC base directory>/erpc_c/setup/erpc_setup_(d)spi_master.cpp

<eRPC base directory>/erpc_c/transports/ erpc_(d)spi_master_transport.hpp

<eRPC base directory>/erpc_c/transports/ erpc_(d)spi_master_transport.cpp

| |UART|<eRPC base directory>/erpc_c/setup/erpc_setup_uart_cmsis.cpp

<eRPC base directory>/erpc_c/transports/erpc_uart_cmsis_transport.hpp

<eRPC base directory>/erpc_c/transports/erpc_uart_cmsis_transport.cpp

|

Client user code

The client's user code is stored in the main_client.c file, located in the *<MCUXpressoSDK_install_dir>/boards/<board_name>/multiprocessor_examples/erpc_client_matrix_multiply_<transport_layer>/* folder.

The eRPC-relevant code with UART as a transport is captured in the following code snippet:

```
...
extern bool g_erpc_error_occurred;
...
/* Declare matrix arrays */
Matrix matrix1 = {0}, matrix2 = {0}, result_matrix = {0};
...
/* UART transport layer initialization, ERPC_DEMO_UART is the structure of CMSIS UART driver␣
↪operations */
erpc_transport_t transport;
transport = erpc_transport_cmsis_uart_init((void *)&ERPC_DEMO_UART);
...
/* MessageBufferFactory initialization */
erpc_mbf_t message_buffer_factory;
message_buffer_factory = erpc_mbf_dynamic_init();
...
/* eRPC client side initialization */
erpc_client_t client;
client = erpc_client_init(transport,message_buffer_factory);
...
/* Set default error handler */
erpc_client_set_error_handler(client, erpc_error_handler);
...
while (1)
{
  /* Invoke the erpcMatrixMultiply function */
  erpcMatrixMultiply(matrix1, matrix2, result_matrix);
  ...
  /* Check if some error occured in eRPC */
  if (g_erpc_error_occurred)
  {
    /* Exit program loop */
    break;
  }
  ...
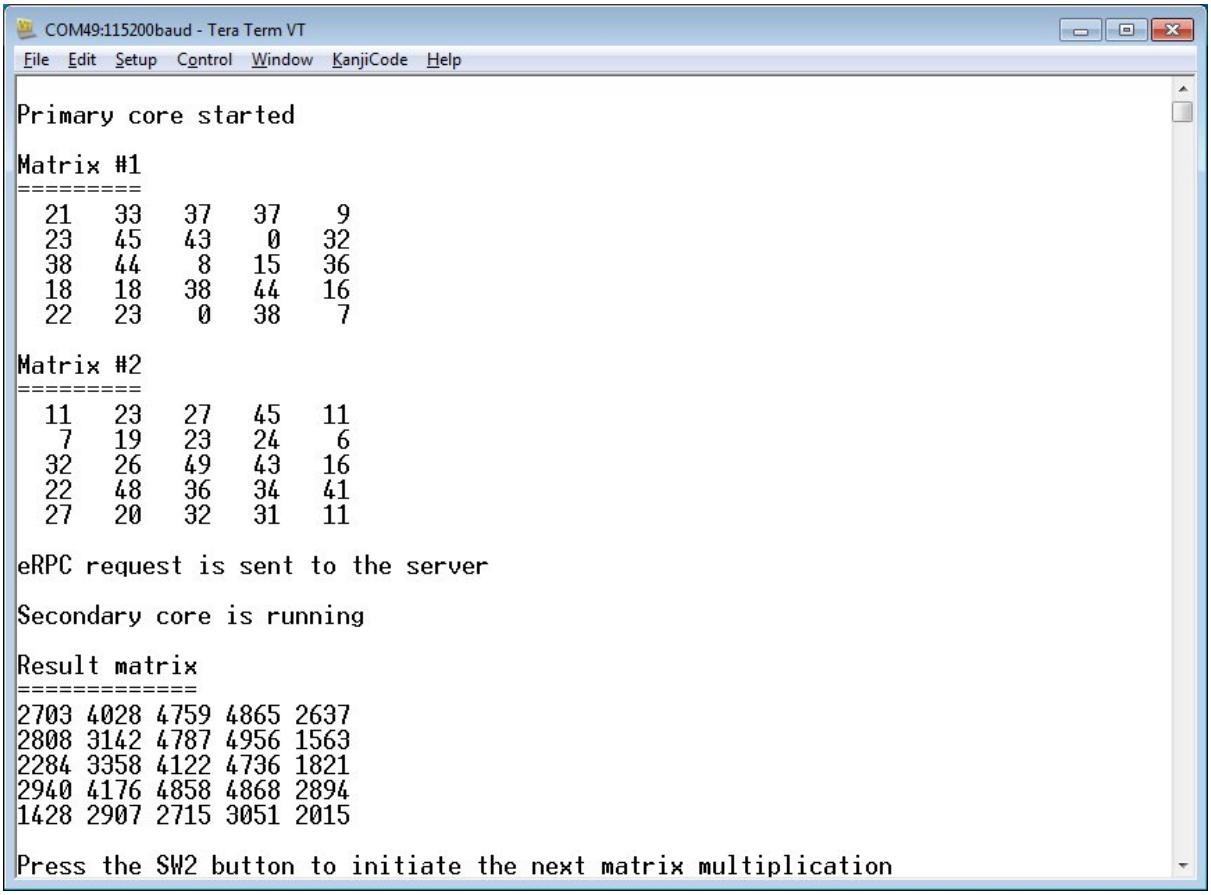
}
```



Parent topic: Multiprocessor client application

Parent topic: Multiprocessor server application

Parent topic:*Create an eRPC application*

Running the eRPC application

Follow the instructions in *Getting Started with MCUXpresso SDK* (document MCUXSDKGSUG) (located in the <*MCUXpressoSDK_install_dir*>/*docs* folder), to load both the primary and the secondary core images into the on-chip memory, and then effectively debug the dual-core application. After the application is running, the serial console should look like:

For multiprocessor applications that are running between PC and the target evaluation board or between two boards, follow the instructions in the accompanied example readme files that provide details about the proper board setup and the PC side setup (Python).

Parent topic:*Create an eRPC application*

Parent topic:*eRPC example*

Other uses for an eRPC implementation

The eRPC implementation is generic, and its use is not limited to just embedded applications. When creating an eRPC application outside the embedded world, the same principles apply. For example, this manual can be used to create an eRPC application for a PC running the Linux operating system. Based on the used type of transport medium, existing transport layers can be used, or new transport layers can be implemented.

For more information and erpc updates see the github.com/EmbeddedRPC.

Changelog eRPC

All notable changes to this project will be documented in this file.

The format is based on Keep a Changelog, and this project adheres to Semantic Versioning.

Unreleased

Added

- Added Zephyr IPC Service transport layer support.
- Zephyr examples added support for RT600 and RT700.

Updated

- eRPC Zephyr module port updated for Zephyr version 4.4

Fixed

- Python code of the eRPC infrastructure was updated to match the proper python code style, add type annotations and improve readability.
- eRPC: Several MISRA violations addressed.

1.14.0

Added

- Added Cmake/Kconfig support.
- Made java code jdk11 compliant, GitHub PR #432.
- Added imxrt1186 support into mu transport layer.
- erpcgen: Added assert for listType before usage, GitHub PR #406.

Fixed

- eRPC: Sources reformatted.
- erpc: Fixed typo in semaphore get (mutex -> semaphore), and write it can fail in case of timeout, GitHub PR #446.
- erpc: Free the arbitrated client token from client manager, GitHub PR #444.
- erpc: Fixed Makefile, install the erpc_simple_server header, GitHub PR #447.
- erpc_python: Fixed possible AttributeError and OSError on calling TCPTransport.close(), GitHub PR #438.
- Examples and tests consolidated.

1.13.0

Added

- erpc: Add BSD-3 license to endianness agnostic files, GitHub PR #417.
- eRPC: Add new Zephyr-related transports (zephyr_uart, zephyr_mbox).
- eRPC: Add new Zephyr-related examples.

Fixed

- eRPC,erpcgen: Fixing/improving markdown files, GitHub PR #395.
- eRPC: Fix Python client TCPTransports not being able to close, GitHub PR #390.
- eRPC,erpcgen: Align switch brackets, GitHub PR #396.
- erpc: Fix zephyr uart transport, GitHub PR #410.
- erpc: UART ZEPHYR Transport stop to work after a few transactions when using USB-CDC resolved, GitHub PR #420.

Removed

- eRPC,erpcgen: Remove cstbool library, GitHub PR #403.

1.12.0

Added

- eRPC: Add dynamic/static option for transport init, GitHub PR #361.
- eRPC,erpcgen: Winsock2 support, GitHub PR #365.
- eRPC,erpcgen: Feature/support multiple clients, GitHub PR #271.
- eRPC,erpcgen: Feature/buffer head - Framed transport header data stored in MessageBuffer, GitHub PR #378.
- eRPC,erpcgen: Add experimental Java support.

Fixed

- eRPC: Fix receive error value for spidev, GitHub PR #363.
- eRPC: UartTransport::init adaptation to changed driver.
- eRPC: Fix typo in assert, GitHub PR #371.
- eRPC,erpcgen: Move enums to enum classes, GitHub PR #379.
- eRPC: Fixed rpmsg tty transport to work with serial transport, GitHub PR #373.

1.11.0

Fixed

- eRPC: Makefiles update, GitHub PR #301.
- eRPC: Resolving warnings in Python, GitHub PR #325.
- eRPC: Python3.8 is not ready for usage of typing.Any type, GitHub PR #325.
- eRPC: Improved codec function to use reference instead of address, GitHub PR #324.
- eRPC: Fix NULL check for pending client creation, GitHub PR #341.
- eRPC: Replace sprintf with snprintf, GitHub PR #343.
- eRPC: Use MU_SendMsg blocking call in MU transport.
- eRPC: New LPSPI and LPI2C transport layers.
- eRPC: Freeing static objects, GitHub PR #353.
- eRPC: Fixed casting in deinit functions, GitHub PR #354.
- eRPC: Align LIBUSBSIO.GetNumPorts API use with libusbsio python module v. 2.1.11.
- erpcgen: Renamed temp variable to more generic one, GitHub PR #321.
- erpcgen: Add check that string read is not more than max length, GitHub PR #328.
- erpcgen: Move to g++ in pytest, GitHub PR #335.
- erpcgen: Use build=release for make, GitHub PR #334.
- erpcgen: Removed boost dependency, GitHub PR #346.
- erpcgen: Mingw support, GitHub PR #344.
- erpcgen: VS build update, GitHub PR #347.
- erpcgen: Modified name for common types macro scope, GitHub PR #337.
- erpcgen: Fixed memcpy for template, GitHub PR #352.
- eRPC,erpcgen: Change default build target to release + adding artefacts, GitHub PR #334.
- eRPC,erpcgen: Remove redundant includes, GitHub PR #338.
- eRPC,erpcgen: Many minor code improvements, GitHub PR #323.

1.10.0

Fixed

- eRPC: MU transport layer switched to blocking MU_SendMsg() API use.

1.10.0

Added

- eRPC: Add TCP_NODELAY option to python, GitHub PR #298.

Fixed

- eRPC: MUTransport adaptation to new supported SoCs.
- eRPC: Simplifying CI with installing dependencies using shell script, GitHub PR #267.
- eRPC: Using event for waiting for sock connection in TCP python server, formatting python code, C specific includes, GitHub PR #269.

- eRPC: Endianness agnostic update, GitHub PR #276.
- eRPC: Assertion added for functions which are returning status on freeing memory, GitHub PR #277.
- eRPC: Fixed closing arbitrator server in unit tests, GitHub PR #293.
- eRPC: Makefile updated to reflect the correct header names, GitHub PR #295.
- eRPC: Compare value length to used length() in reading data from message buffer, GitHub PR #297.
- eRPC: Replace EXPECT_TRUE with EXPECT_EQ in unit tests, GitHub PR #318.
- eRPC: Adapt rpmsg_lite based transports to changed rpmsg_lite_wait_for_link_up() API parameters.
- eRPC, erpcgen: Better distuingish which file can and cannot by linked by C linker, GitHub PR #266.
- eRPC, erpcgen: Stop checking if pointer is NULL before sending it to the erpc_free function, GitHub PR #275.
- eRPC, erpcgen: Changed api to count with more interfaces, GitHub PR #304.
- erpcgen: Check before reading from heap the buffer boundaries, GitHub PR #287.
- erpcgen: Several fixes for tests and CI, GitHub PR #289.
- erpcgen: Refactoring erpcgen code, GitHub PR #302.
- erpcgen: Fixed assigning const value to enum, GitHub PR #309.
- erpcgen: Enable runTesttest_enumErrorCode_allDirection, serialize enums as int32 instead of uint32.

1.9.1

Fixed

- eRPC: Construct the USB CDC transport, rather than a client, GitHub PR #220.
- eRPC: Fix premature import of package, causing failure when attempting installation of Python library in a clean environment, GitHub PR #38, #226.
- eRPC: Improve python detection in make, GitHub PR #225.
- eRPC: Fix several warnings with deprecated call in pytest, GitHub PR #227.
- eRPC: Fix freeing union members when only default need be freed, GitHub PR #228.
- eRPC: Fix making test under Linux, GitHub PR #229.
- eRPC: Assert costumizing, GitHub PR #148.
- eRPC: Fix corrupt clientList bug in TransportArbitrator, GitHub PR #199.
- eRPC: Fix build issue when invoking g++ with -Wno-error=free-nonheap-object, GitHub PR #233.
- eRPC: Fix inout cases, GitHub PR #237.
- eRPC: Remove ERPC_PRE_POST_ACTION dependency on return type, GitHub PR #238.
- eRPC: Adding NULL to ptr when codec function failed, fixing memcpy when fail is present during deserialization, GitHub PR #253.
- eRPC: MessageBuffer usage improvement, GitHub PR #258.
- eRPC: Get rid for serial and enum34 dependency (enum34 is in python3 since 3.4 (from 2014)), GitHub PR #247.

- eRPC: Several MISRA violations addressed.
- eRPC: Fix timeout for Freertos semaphore, GitHub PR #251.
- eRPC: Use of rpmsg_lite_wait_for_link_up() in rpmsg_lite based transports, GitHub PR #223.
- eRPC: Fix codec nullptr dereferencing, GitHub PR #264.
- erpcgen: Fix two syntax errors in erpcgen Python output related to non-encapsulated unions, improved test for union, GitHub PR #206, #224.
- erpcgen: Fix serialization of list/binary types, GitHub PR #240.
- erpcgen: Fix empty list parsing, GitHub PR #72.
- erpcgen: Fix templates for malloc errors, GitHub PR #110.
- erpcgen: Get rid of encapsulated union declarations in global scale, improve enum usage in unions, GitHub PR #249, #250.
- erpcgen: Fix compile error:UniqueIdChecker.cpp:156:104:'sort' was not declared, GitHub PR #265.

1.9.0

Added

- eRPC: Allow used LIBUSBSIO device index being specified from the Python command line argument.

Fixed

- eRPC: Improving template usage, GitHub PR #153.
- eRPC: run_clang_format.py cleanup, GitHub PR #177.
- eRPC: Build TCP transport setup code into liberpc, GitHub PR #179.
- eRPC: Fix multiple definitions of g_client error, GitHub PR #180.
- eRPC: Fix memset past end of buffer in erpc_setup_mbf_static.cpp, GitHub PR #184.
- eRPC: Fix deprecated error with newer pytest version, GitHub PR #203.
- eRPC, erpcgen: Static allocation support and usage of rpmsg static FreeRTOSs related APi, GitHub PR #168, #169.
- erpcgen: Remove redundant module imports in erpcgen, GitHub PR #196.

1.8.1

Added

- eRPC: New i2c_slave_transport trasnport introduced.

Fixed

- eRPC: Fix misra erpc c, GitHub PR #158.
- eRPC: Allow conditional compilation of message_loggers and pre_post_action.
- eRPC: (D)SPI slave transports updated to avoid busy loops in rtos environments.
- erpcgen: Re-implement EnumMember::hasValue(), GitHub PR #159.
- erpcgen: Fixing several misra issues in shim code, erpcgen and unit tests updated, GitHub PR #156.

- erpcgen: Fix bison file, GitHub PR #156.

1.8.0

Added

- eRPC: Support win32 thread, GitHub PR #108.
- eRPC: Add mbed support for malloc() and free(), GitHub PR #92.
- eRPC: Introduced pre and post callbacks for eRPC call, GitHub PR #131.
- eRPC: Introduced new USB CDC transport.
- eRPC: Introduced new Linux spidev-based transport.
- eRPC: Added formatting extension for VSC, GitHub PR #134.
- erpcgen: Introduce ustring type for unsigned char and force cast to char*, GitHub PR #125.

Fixed

- eRPC: Update makefile.
- eRPC: Fixed warnings and error with using MessageLoggers, GitHub PR #127.
- eRPC: Extend error msg for python server service handle function, GitHub PR #132.
- eRPC: Update CMSIS UART transport layer to avoid busy loops in rtos environments, introduce semaphores.
- eRPC: SPI transport update to allow usage without handshaking GPIO.
- eRPC: Native _WIN32 erpc serial transport and threading.
- eRPC: Arbitrator deadlock fix, TCP transport updated, TCP setup functions introduced, GitHub PR #121.
- eRPC: Update of matrix_multiply.py example: Add –serial and –baud argument, GitHub PR #137.
- eRPC: Update of .clang-format, GitHub PR #140.
- eRPC: Update of erpc_framed_transport.cpp: return error if received message has zero length, GitHub PR #141.
- eRPC, erpcgen: Fixed error messages produced by -Wall -Wextra -Wshadow -pedantic-errors compiler flags, GitHub PR #136, #139.
- eRPC, erpcgen: Core re-formatted using Clang version 10.
- erpcgen: Enable deallocation in server shim code when callback/function pointer used as out parameter in IDL.
- erpcgen: Removed '$' character from generated symbol name in '_$union' suffix, GitHub PR #103.
- erpcgen: Resolved mismatch between C++ and Python for callback index type, GitHub PR #111.
- erpcgen: Python generator improvements, GitHub PR #100, #118.
- erpcgen: Fixed error messages produced by -Wall -Wextra -Wshadow -pedantic-errors compiler flags, GitHub PR #136.

1.7.4

Added

- eRPC: Support MU transport unit testing.
- eRPC: Adding mbed os support.

Fixed

- eRPC: Unit test code updated to handle service add and remove operations.
- eRPC: Several MISRA issues in rpmsg-based transports addressed.
- eRPC: Fixed Linux/TCP acceptance tests in release target.
- eRPC: Minor documentation updates, code formatting.
- erpcgen: Whitespace removed from C common header template.

1.7.3

Fixed

- eRPC: Improved the test_callbacks logic to be more understandable and to allow requested callback execution on the server side.
- eRPC: TransportArbitrator::prepareClientReceive modified to avoid incorrect return value type.
- eRPC: The ClientManager and the ArbitratedClientManager updated to avoid performing client requests when the previous serialization phase fails.
- erpcgen: Generate the shim code for destroy of statically allocated services.

1.7.2

Added

- eRPC: Add missing doxygen comments for transports.

Fixed

- eRPC: Improved support of const types.
- eRPC: Fixed Mac build.
- eRPC: Fixed serializing python list.
- eRPC: Documentation update.

1.7.1

Fixed

- eRPC: Fixed semaphore in static message buffer factory.
- erpcgen: Fixed MU received error flag.
- erpcgen: Fixed tcp transport.

1.7.0

Added

- eRPC: List names are based on their types. Names are more deterministic.
- eRPC: Service objects are as a default created as global static objects.

- eRPC: Added missing doxygen comments.
- eRPC: Added support for 64bit numbers.
- eRPC: Added support of program language specific annotations.

Fixed

- eRPC: Improved code size of generated code.
- eRPC: Generating crc value is optional.
- eRPC: Fixed CMSIS Uart driver. Removed dependency on KSDK.
- eRPC: Forbid users use reserved words.
- eRPC: Removed outByref for function parameters.
- eRPC: Optimized code style of callback functions.

1.6.0

Added

- eRPC: Added @nullable support for scalar types.

Fixed

- eRPC: Improved code size of generated code.
- eRPC: Improved eRPC nested calls.
- eRPC: Improved eRPC list length variable serialization.

1.5.0

Added

- eRPC: Added support for unions type non-wrapped by structure.
- eRPC: Added callbacks support.
- eRPC: Added support @external annotation for functions.
- eRPC: Added support @name annotation.
- eRPC: Added Messaging Unit transport layer.
- eRPC: Added RPMSG Lite RTOS TTY transport layer.
- eRPC: Added version verification and IDL version verification between eRPC code and eRPC generated shim code.
- eRPC: Added support of shared memory pointer.
- eRPC: Added annotation to forbid generating const keyword for function parameters.
- eRPC: Added python matrix multiply example.
- eRPC: Added nested call support.
- eRPC: Added struct member “byref” option support.
- eRPC: Added support of forward declarations of structures
- eRPC: Added Python RPMsg Multiendpoint kernel module support
- eRPC: Added eRPC sniffer tool

1.4.0

Added

- eRPC: New RPMsg-Lite Zero Copy (RPMsgZC) transport layer.

Fixed

- eRPC: win_flex_bison.zip for windows updated.
- eRPC: Use one codec (instead of inCodec outCodec).

[1.3.0]

Added

- eRPC: New annotation types introduced (@length, @max_length, ...).
- eRPC: Support for running both erpc client and erpc server on one side.
- eRPC: New transport layers for (LP)UART, (D)SPI.
- eRPC: Error handling support.

[1.2.0]

Added

- eRPC source directory organization changed.
- Many eRPC improvements.

[1.1.0]

Added

- Multicore SDK 1.1.0 ported to KSDK 2.0.0.

[1.0.0]

Added

- Initial Release

3.4 Wireless

3.4.1 NXP Wireless Framework and Stacks

NXP Bluetooth LE Host and Sample Applications

Changelog All notable changes to NXP Bluetooth LE Host will be documented in this file.

NXP Bluetooth LE Host Stack is certified **Bluetooth 6.3**

[1.10.23] - mcux v2026-09-00

Note: Version 1.10.23 is the first NXP Bluetooth LE Host release officially certified according to the Bluetooth® Core Specification Version 6.3

Added

- Bluetooth Sample Applications support for the KW43-LOC board
- Support in Wireless Uart for NBU core-dump packet reception (gEnableCoredumpPackets)

Improved

- Optimised stack sizes for the PSA module (frdmmcxw70/frdmkw43)
- Added MinimalHeapSize_c to all localization applications, scaled for RADE2 and number of connections
- Optimized memory buffer values in the loc_reader Channel Sounding application
- Reworked setcsconfig and setcsproc shell commands for per-parameter updates in localization applications
- Updated wireless ranging Python host application setup documentation (Python 3.12+ supported)
- Updated CCC Digital Key R3 Application Note connection handover features

Fixed

- Fixed ExtendedFeatures mismatch between GAPInit and HCI LE Read All Remote Features Complete event
- Fixed EATT out-of-bounds read in IsEnhncdChanReconfInProgress()
- Fixed CCC demo CS ranging procedure counter wrapping past 0xFFFF
- Fixed GattDbDynamic_AddCharServiceChanged using Notify instead of Indicate property
- Fixed ShellGap_ConnectFromPawr setting the success status incorrectly
- Miscellaneous Coverity fixes
- Miscellaneous CERT-C fixes
- Miscellaneous MISRA fixes

Changed

- Bluetooth 6.3 Compliance: removed Data Signing (LE Security Mode 2)

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23, KW43, MCXW70

[1.10.22] - mcux v2026-09-00-pvw2

Added

- Added gSecEvt_SameConfirmValue_c IDS event to detect Legacy Pairing Confirm Value replay attacks

Improved

- Replaced mode assert with graceful drop and cleanup in localization applications

- RAS/RAP: handle case where MTU size reduction forces use of more segments than predefined gRASMaxNoOfSegments_c
- Advertising-set-related BLE Host storage is now allocated by the application and scales with the configurable gMaxAdvSets_c

Fixed

- Fixed CS measurement not starting after handover in digital_key_car_anchor_cs
- Fixed Insufficient Encryption returned instead of Insufficient Authentication
- Fixed RSSI filter not excluding invalid RSSI values in CCC monitoring
- Fixed missing CCC characteristics in digital_key_car_anchor_cs example
- Fixed mismatch between ExtendedFeatures from GAPInit and HCI LE Read All Remote Features Complete event
- Miscellaneous Sample Applications fixes
- Miscellaneous Coverity fixes
- Miscellaneous MISRA fixes

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23, KW43, MCXW70

[1.10.21] - mcux v2026-09-00-pvw1

Added

- RSSI-based adaptive CS procedure interval for localization applications (experimental; disabled by default)
- Added BTCS timer mechanism to ensure CS procedure loop restarts are not blocked by failed L2CAP transfers

Improved

- CS procedure parameters are now updated on connection interval change to avoid CS request rejection
- Aligned wireless_uart preinclude settings across all platforms for consistency
- Updated ble_shell periodic advertising default interval set to 1 second for improved discoverability
- Increased host task stack size across multiple applications
- Extended ble_shell periodic advertising handling to support gPeriodicDeviceScannedV2_c event
- RADE component naming updated in documentation
- Unified CS results complete event handling; real-time transfer moved to AppLocalization_HandleCompleteResults()

Fixed

- Fixed out-of-bounds access in gap.c
- HCI LE Read All Remote Features command is now issued if supported by the controller
- Power Control APIs now return gBleFeatureNotSupported_c if the controller does not indicate support

- Fixed array index overflow in application ranging_client.c
- Fixed local RSSI parsing: correct byte is now collected before advancing parse pointer
- Fixed bounds check for gaAntPermNAp in processMode2Data and processMode3Data
- Fixed localization index overflow; added sanity check
- Corrected bounds check for deviceId
- Fixed wireless_uart mAdvPending flag to prevent multiple advertising starts during multi-peer disconnect
- Fixed missing RSSI variables causing compilation issues in app_localization_utils.c
- TPMS sensor Signing Key and sequence number now saved in NVM to prevent MAC check failures
- CS IPT mode now configured with only 1 antenna path to fix Samsung phone CS request rejection
- FSCI Extended NBU: Added LL_API_NotifyWakeUp call in idle_task to detect NBU stuck condition; added leExtendedFeatures to NCP GAP init complete event
- Fixed systick drift when PWR_DisallowDeviceToSleep() is active
- CS: Added check for valid numAntennaPaths in processCsResultsEvent
- Miscellaneous MISRA fixes
- Miscellaneous Coverity fixes

Changed

- Reverted incorrect connection handle handling for non-connection enhanced notification events

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23, KW43, MCXW70

[1.10.20] - mcux v2026-06-00

Added

- Tire Pressure Monitoring System (TPMS) sample demo applications (KW4x)
- Tire Pressure Monitoring System (TPMS) documentation added to DAUG
- Localization accelerator LCE support for KW43/MCXW70
- Added LE Power Control support in BLE Shell application
- LE Read All Remote Features (LLEFS) support in HOST-GAP
- LE Channel Assessment (CHAS) Config HCI command support in HOST-GAP
- Sensor support enabled on KW43/MCXW70

Improved

- CS procedure auto-loop shell command; improved RAS data drop mechanism
- Allow ‘setnumprocs’ 0 for infinite CS procedure repeats
- Synchronize code between loc_reader and ncp_loc_reader application files
- Subevent interval added to RADE algoritm API

- Updated connection handover setup info for FRDM-KW43 in CS application documentations
- Documentation updates

Fixed

- L2CAP data fragmentation fix causing inccorect fragmentation over the air
- Fix for no valid subevents in localization
- Allow sub_mode_type 255 in CS config params
- Incorrect connection handle (0 instead of 0xFFFF) for non-connection enhanced notification events
- Channel Sounding subevent abort (No CS_SYNC mode0) after rebond
- Set 'preferredPeerAntenna' based on peer capabilities
- Miscellaneous minor application bug fixes

Changed

- Reduced cyclomatic complexity (CCM) in multiple localization functions
- Decoupled buttons from LEDs in Bluetooth applications

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23, KW43, MCXW70

[1.10.19] - mcux v2026-06-00-pvw2

Added

- Support for LE Read All Remote Features after connection is established
- Experimental Inline PCT Transfer support for localization sample applications
- Support for configurable limits for concurrent Channel Sounding connections/procedures

Improved

- Optimized memory allocation in isp_mciq_ranging_compute for localization applications
- Updated RAS loc_reader application for multiple CS connections
- Updated handover documentation with broadcast time synchronization details
- Documentation updates

Fixed

- Fixed double free issue in L2ca_SendAclDataWithSegmentation
- Fixed consecutive CS procedures sustainability issue
- Miscellaneous minor application bug fixes

Changed

- CS procedure state management: do not allow new procedure to start before previous one completes

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23, KW43

[1.10.18] - mcux v2026-06-00-pvw1

Added

- Support for RTT 0 m calibration in applications.
- Support for CS Enhancements at Host level:
  - Inline PCT Transfer
  - RTT 2M PHY
- New connection event 'gConnEvtRemoteFeaturesRead_c', providing the peer feature bitmask read via the Read Remote Features procedure
- Support for 5 advertising sets in the Bluetooth LE Host
- Method to specify GATT handles on the client, avoiding repeated service discovery
- Slope calibration algorithm for CS (experimental, disabled by default). Computes distance and quality indicators per antenna path
- Handover broadcast time synchronization, allowing one connected anchor to synchronize multiple target anchors simultaneously
- Added common configuration header 'app_localization_config.h', overridable by the user

Improved

- Updated handling of 'Procedure_Results_Start' to correctly process multiple subevents in a single message
- Improved CS temperature polling mechanism
- BTCS Server now explicitly notifies the PSM channel via 'AppLocalization_SetPsmChannelId' upon handover connection
- RAS/BTCS clients can disable algorithm execution via 'gRunAlgo_d'
- Updated and cleaned 'app_preinclude.h' for sample applications
- Documentation and configuration updates for LCE enable/disable
- Documentation updates
- Miscellaneous minor application bug fixes

Fixed

- If the LE Set Periodic Adv Subevent Data command finishes with an error, use 'gInternalError_c' with 'gLeSetPeriodicAdvSubeventData_c' as the source and the command complete status as the error code
- Correct handling of AddrType values in MonAdvReport generated from XML

Changed

- Removed the Bluetooth LE Host library from the wireless_uart_host project
- Disabled use of Random Static Address for all applications except: digital_key_car_anchor and digital_key_car_anchor_cs
- Set maximum CS procedure duration to: (procedure interval x connection interval x 2 - 1) slots

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23

[1.10.17] - mcux v2026-03-00

Added

- Test mode functionality for the Intrusion Detection System
- GAP API for HCI LE_Set_Local_Slave_Latency_Enable vendor command
- gRasUseNotifOrInd_c to allow configuration of Indication or Notification on RAS
- cs_sync_phy argument to setcsconfig shell command
- snr_control_init and snr_control_refl arguments to setcsproc shell command
- Detailed description for setcsconfig and setcsproc command arguments to the CCC w/ CS and Localization applications notes
- Mode0 step information parsing for both RAS and BTCS, made available for the export module

Improved

- ATT Write Commands can now be sent at any time, as per specification
- Enhanced CCC and RAS Channel Sounding by incorporating real-time local and remote data decompression
- Localization applications now record the PHY used for establishing the connection and incorporate it into the CS procedure parameters configuration
- Localization applications keep the subevtStopIdx for the remote data and provide it to the algorithm
- Localization applications now pass remote mode map to algorithm
- Eliminated the dependency on hci_interface.h in localization files
- Documentation updates
- Miscellaneous minor application bug fixes

Fixed

- Wrong data field type in GAP2GenericEventVendorSpecificDebugFatalError
- Localization application now processes CS results only when local data is available
- Digital key car anchor application issue related to setting the GAP role prior to any use
- Error in the definition of a CCC PSM VDBT Version GATT characteristic
- Issue with PACKET_NADM byte not being packed correctly into the TOF buffer for mode-3 steps
- MISRA fixes

Changed

- Modified linker section names, comments, and RAM layout in the connectivity.icf and connectivity_ble_loc.ld files for every KW47 and MCXW72 board
- Set the default CS submode and default rtt_type to 3
- Set the default radio core speed for the Channel Sounding application to 48 MHz

- Localization applications configured to use the extended heap as the final segment of DATA1
- Deleted the gcGapMaximumActiveConnections_c definition from applications
- Eliminated unused fields related to CS Test Mode
- Deleted initializations of range settings that were subsequently overwritten

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23

[1.10.16] - mcux v2026-03-00-pvw2

Added

- Implemented Bluetooth LE Host Transient Application Key feature (experimental). in ble_shell, loc_reader and loc_user_device
- Added Bluetooth LE Host Transient Application Key in ble_shell, loc_reader and loc_user_device
- Added Channel Sounding phase calibration, with 0.5m compensation for all boards
- Added Vendor Specific Command to enable Link Layer experimental features
- Added gAppCsTimeInfo_d define in app_preinclude.h for digital_key_car_anchor_cs on KW47EVK
- Added Channel Sounding **phase calibration** logic and updates in RAS CS Procedure Timing Measurement

Improved

- Updated RADE algorithm source files license description with NXP proprietary license
- Improved data logging for digital key application
- Updated CCC enumeration values to align with CCC v4.0.0 specification
- Updated Intrusion Detection System documentation with event details
- Documentation miscellaneous updates

Fixed

- Fixed ranging data body parser on the client side — aborted steps are now counted correctly to prevent subevent misalignment
- Fixed handling of CS Procedure Disable at Host and application level
- Fixed app_localization timer blocking when sensors were disabled
- Fixed setting of gCsTimeInfo.transferStart for BTCS Client L2CAP transfer
- Removed unused gAppRealTimeDataTransfer_c define from digital_key_car_anchor_cs
- Removed pin_mux files from core1 application projects
- Fixed issues in data transfer and event updates related to timing measurement

Changed

- Updated (SHELL_MAX_ARGS = 20) in app_preinclude.h for localization applications.

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23

[1.10.15] – mcux v2026-03-00-pvw1

Added

- Added an API to update local synchronization parameters after PAwR is already established on the scanner side
- Added Connection Subrating feature (experimental) in the Bluetooth LE Host
- Added Connection Subrating feature in ble_shell
- CCC v4.1.0: renamed DK_VERSION to VDBT_VERSION as per updated specification

Improved

- Improved localization applications timer mechanism to reduce the number of wakeups
- Updated localization timeout values to be overridable by the application
- Retain the subevent_done_status local and remote values for all subevents and pass them to the algorithm
- Documentation miscellaneous updates

Fixed

- Fixed L2CAP credit-based channel disconnection where the channel's timer ID would be set to 0 instead of gTmrInvalidTimerID_c
- Fixed Channel Sounding applications issue: clear the Indication Pending flag for a peer device on disconnect
- ble_shell: Set maximum arguments in command (SHELL_MAX_ARGS = 20) in app_preinclude.h

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23

[1.10.14] - mcux v2025-12-00

Added

- KW47/MCXW72 CCC and IOT Channel Sounding Localization applications on GitHub repository
- Monitoring Advertisers support in fsci_black_box and BleShell applications
- Local average and remote average RSSI values to the CS measurement report
- The "-Os" optimization flag to the ARMGCC release configuration for NCP applications

Improved

- Enabled low power support in loc_reader_host application

Fixed

- loc_reader_host application event set issue
- Missing handler for Version2 of the Set RPA Timeout command

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23

[1.10.13] - mcux v2025-12-00-pvw2

Added

- Threshold for the invalid number of Anchor Monitor events received by the target anchor
- **Experimental Monitoring Advertisers** feature in Bluetooth LE Host
- **Experimental Randomized RPA** feature in Bluetooth LE Host
- Application defines for default connection and default advertising tx power

Improved

- Miscellaneous applications updates
- Central applications now wait for status of Encrypt procedure in case of bonded device
- Logging data on localization applications
- NBU Low Power Mode enabled by default for Localization Applications
- PCT rotation calibration added to localization apps
- Configured CS Reflector to start the CS procedure with the tdm command and updated the documentation
- Populated the optionalSubfeaturesSupported field correctly
- Prevented CORE 0 from entering deep sleep while LCE is computing by setting the low power mode constraint to PWR_WFI during LCE computation and releasing it afterwards
- Implemented in CCC_CS, Channel Sounding data transfer from the anchor to the device
- Documentation miscellaneous updates
- Updated all kw47 and kw45 armgcc ld linker files to take gUseInternalStorageLink_d flag value into consideration

Fixed

- Memory issue when setting scan response data would return an error status from the LL
- Set advertises with the public address, overwritten by a previously used random address on receiving the Advertising Set Terminated event

Changed

- Updated memory configuration: replaced the extended heap area in the available SMU2 memory with a 24KB array in the data1
- Removed redundant cached remote capabilities write on reflectors, as the initiator will always trigger a capabilities exchange and trying to write cached capabilities afterwards results in an HCI error

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23

[1.10.12] - mcux v2025-12-00-pvw1

Added

- **Gap_LoadCustomBondedDeviceInformation API** to retrieve custom peer information using NVM index

Improved

- Miscellaneous application updates

Fixed

- **Updated privacy timeout** mechanism affected by LE Set Extended Advertising Enable Command

Changed

- Merged **Gap_SetPeriodicAdvParameters** and Gap_SetPeriodicAdvParametersV2 into Gap_SetPeriodicAdvParameters

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23

[1.10.11] - mcux v2025-09-00

Added

- CCC sample applications updated to **CCC Digital Key v4.0.0** Specification
- **RAS/RAP PTS** 8.7.4 test support added in Localization Sample applications
- Support for CS start procedure while the previous procedure is not completed; old procedure replaced with the new one
- Support for arm gcc for ncp_loc_reader__cm33_core1

Improved

- Localization Sample Applications Ram partition
- **RAS/RAP** profile and service
- Various sample applications have been updated

Fixed

- Privacy setting issue on ncp_loc_reader
- Extended NBU FSCI message handling issue
- Ble_shell updated to set the Random Static Address properly
- Always set the Advertising Legacy Set handle if the legacy API was used
- fsci_bridge and w_uart_host memory leak
- PAWR parameters in PeriodicSyncTransferReceived are now parsed correctly
- Ensure an RPA/NRPA is properly set from the application to enable a central using Controller Privacy to connect to unbonded peripherals
- CS algorithm buffer overwrite issue during Connection Handover application
- Various sample applications bug fixes applied
- Pass correct Codded PHY (S2) to Channel Sounding Set Procedure Parameters

Changed

- Merged Gap_SetExtAdvertisingParameters and Gap_SetExtAdvertisingParametersV2 into **Gap_SetExtAdvertisingParameters**
- ce_status_buffer type changed to int32_t
- BLE_Shell prints Random Static address as identity address instead of the Public Device Address

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23

[1.10.10] - mcux v2025-09-00-pvw2

Improved

- **CS Event Handling**: CS (Channel Sounding) events are now sent to the application task for processing, rather than being handled directly in the Host task
- Various sample applications have been updated

Fixed

- Bluetooth Advertising Sets: Now supports **4 advertising** sets in the Bluetooth host libraries
- Various sample applications bug fixes applied

Changed

- Bluetooth Address Type: The default address type has been changed from **Public to Random Static**

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23

[1.10.9] - mcux v2025-09-00-pvw1

Added

- **IDS event** trigger when incoming ATT packets exceed agreed MTU
- **IDS event** trigger when Unexpected SMP Messages received in idle states (before pairing starts)
- Average RSSI reporting in Anchor Monitor event
- Support for gAppDeferAlgoRun_d in btcs_client.c
- **Multi-connection monitoring** in Handover/Monitor Mode

Improved

- Updated **NBU channel sounding** applications to support **64MHz** clock speed
- Cleanup of commComplete structures that only contain status from hci_interface.h

Fixed

- CCC Application handover monitoring RSSI issue
- Intrusion Detection System not reporting event type

- Extended **NBU armgcc projects** stability
- Advertising Extended Applications when Gap_PeriodicAdvCreateSync fails

Changed

- Updated digital_key_car_anchor applications to configure coding scheme via Host API
- Enhanced RAS handling of ACK Ranging Data in invalid conditions

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23

[1.10.8] - mcux v2025-06-00

Added

- **Gap_SetBondedDeviceName()** to set device name using NVM index
- **RAS** queue for GATT indications sent
- **gHciStatusBase_c** to **csError** status
- Option to use statically allocated **memory** for dynamic **GATT database** (prevents heap fragmentation)
- Checks for **controller** supported features and setting **PAST bits** accordingly
- **Anchor** support to **export** device data via RAS using gAppHciDataLogExport_d = 2
- **Anchor** support to **export** device local HCI data using gAppHciDataLogExport_d = 1
- **Shell commands** to list peer devices and trigger connection handover
- Define for **enabling** optional **CCC** LE Coded **PHY** advertising
- **cs_sync_phy** parameter to mDefaultRangeSettings (**renamed** from outdated RTTPhy)

Improved

- **Stack Host** now saves the most recently set **random address** after successful controller response
- Miscellaneous **minor** application **updates**

Fixed

- Compilation issue in **loc_reader app** with real-time RAS transfer
- **CCC** application **handover state machine** race condition
- **CCC** resets **gCurrentAdvHandle** upon connection
- **RAS** uses correct bit for data overwrite preference

Changed

- Updated **Bluetooth LE Host Documentation**.
- **BLE_Shell** Tx timer interval adjusted for **max throughput** on 1M PHY
- **CS_ConfigVendorCommand** updated with **Inline Phase Return** field
- Renamed **tx_pwr_phy** to **phy** and removed obsolete rtt_phy field
- Updated **documentation** to clarify **Controller Privacy** restrictions

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, MCXW23

[1.10.7] - mcux v2025-06-00-pvw2

Added

- Support for **Bluetooth LE Debug Keys**
- Support for **pairing failure** reason 0x10 (Busy)
- Extended NBU **Wireless_uart_host battery service**
- **Channel Sounding RSSI Information** at application level
- Application support for **4-antenna configuration**

Improved

- **Clean** include directives
- Allow central-only devices to use **Gap_EncryptAdvertisingData**
- **CSTACK** size optimization for **RADE** using baremetal apps

Fixed

- Extended NBU **memory leak** issues
- Issues when **gAppOtaASyncFlashTransactions_c** is set to 0
- Issue with **CS procedure** affected by the CS data export
- Extended NBU **Wireless_uart_host privacy**

Changed

- Updated **Bluetooth LE Host Documentation**.

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, K32W1

[1.10.6] - mcux v2025-06-00-pvw1

Added

- **Encypted Advertising Data** support in Extendded Advertising Applications.
- Support for **disable UART** for **CS applications** for **low power measurements**.
- Support for **LCE (DSPV) non-blocking API** integration to **RADE**.
- **Intrusion Detection System** as **Experimental**.

Improved

- **L2CAP command length validation** to cover all signaling commands.
- **Extended NBU Wireless_uart_host multiple connections** support.

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, K32W1

[1.10.5] - mcux v2025-03-00

Added

- MCXW72 **Extended NBU** support and **w_uart_host**, **fsci_bridge** and **ncp_fscibb** sample applications.
- **L2CAP support** for Channel Sounding **IQ Sample Transfer** in CCC CS sample applications.
- Bluetooth LE Sample applications for **MCX-W71-EVK** board.

Changed

- Updated **FSCI XML file**.
- Updated **Bluetooth LE Host Documentation**.

Fixed

- Cleared the **mpRemoteCachedCaps** entry when the peer disconnects (CS sample applications).
- Transfer **RAS subscription** data during connection handover (CCC CS sample applications).
- **EAD** - Updated advertising data length check to ensure encrypted data fits inside one AD.
- Updated **digital_key_car_anchor** and **digital_key_car_anchor_cs** applications to manage **Random Static address** from the application layer.

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, K32W1

[1.10.4] - mcux v2025-03-00-pvw2

Added

- PAWR support in **BLE Shell** sample application.
- PAWR support in **adv_ext_peripheral** and **adv_ext_central** sample applications.
- New sample applications for **FRDM-MCXW72**.
- **Gap_SetScanningCallback** API.
- Support for handover connection interval update command.

Changed

- Updated HID Device for **Windows 11** compatibility.
- Updated CCC demos to **Digital Key R4 spec version 1.0.0**.
- Improved RPA resolution at the **Host level**, now performed synchronously.
- Enhanced parsing of the **CS procedure** in Ranging Service.

Fixed

- Corrected parsing of the **PAST command** in FSCI GAP.
- Fixed **scan event reporting** in PAST scenario.
- Added an error case for Gap_SetChannelMap in the generic event handler.

Supported Platforms

- KW45, KW47, MCXW71, MCXW72, K32W1

Bluetooth Low Energy Application Developer's Guide Introduction

This document explains how to integrate the NXP Bluetooth Low Energy Host Stack in an application and provides detailed explanation of the most commonly used APIs and code examples.

- *Introduction*: This section outlines the document structure.
- *Prerequisites*: The document sets out the prerequisites.
- *Bluetooth LE Host Stack Initialization and APIs*: This section describes the Bluetooth Low Energy Host Stack initialization. It also presents the APIs categorized according to the layer and by application role.
- *Generic Access Profile (GAP) Layer*: The Generic Access Profile (GAP) layer is divided into two sections according to the GAP role of the device: Central and Peripheral. The basic setup of two such devices is explained with code examples, such as how to prepare the devices for connections, how to connect them together, and pairing and bonding processes.
- *Generic Attribute Profile (GATT) Layer*: This section describes the Generic Attribute Profile (GATT) layer and introduces the APIs required for data transfer between the two connected devices. This section is divided into two subsections according to the GATT role of the device: Client and Server.
- *GATT database application interface*: The document further describes the usage of the GATT database APIs that allow the application to manipulate data stored in the GATT Server database.
- *Creating GATT database*: This section describes a user-friendly method to build a GATT database statically. The method involves the use of a predefined set of macros that the application can include to build the database at application compile time.
- *Creating a Custom Profile*: This section contains instructions on how to build a custom profile.
- *Application Structure*: The section describes the structure of the typical application.
- *Low-Power Management*: This section describes low-power management and how an application can use the low-power modes of the hardware and software.
- *Over the Air Programming (OTAP)*: This section describes the Over The Air Programming (OTAP) capabilities that the Host Stack offers via a dedicated Service/Profile. The section also describes how to use the OTAP capabilities in an application and also contains a detailed description of the SDK components involved in the OTAP process.
- *Creating a Bluetooth LE application when the Host Stack runs on another processor*: This section describes how to build a Bluetooth Low Energy application when the Host Stack is running on a separate processor.
- *Intrusion Detection System*: This section describes the usage of the Intrusion Detection System (IDS).
- *References*: This section lists the documents that can be referred to for more information.
- *Acronyms and abbreviations*: This section lists the acronyms used in this document.

Prerequisites

The Bluetooth Low Energy Host Stack library contains several external references that the application must define to enable full functionality.

Attention: Application developers must ensure to define these references to prevent linkage errors when trying to build the application binary.

Task and event queues

The task queues are declared in the *ble_host_tasks.h* as follows:

```
/*! App to Host message queue for the Host Task */
    extern messaging_t    gApp2Host_TaskQueue;
/*! HCI to Host message queue for the Host Task */
    extern messaging_t    gHci2Host_TaskQueue;
/*! Event for the Host Task Queue */
    extern OSA_EVENT_HANDLE_DEFINE(gHost_TaskEvent);
```

See Initialization for more details about the RTOS tasks required by the Bluetooth LE Host Stack.

Parent topic:*Prerequisites*

GATT database

The application must define and populate the database according to its requirements and constraints either statically, at application compile time, or dynamically.

Regardless of how the application creates the GATT database, the following two external references from *gatt_database.h* must be defined:

```
/*! The number of attributes in the GATT Database. */
extern uint16_t gGattDbAttributeCount_c;
/*! Reference to the GATT database */
extern gattDbAttribute_t* gattDatabase;
```

The attribute template is defined as shown here:

```
typedef struct{
    uint16_t handle ;
/*!< Attribute handle - cannot be 0x0000; attribute handles need not be consecutive, but must be strictly␣
↪increasing. */
    uint16_t permissions ;
/*!< Attribute permissions as defined by ATT. */
    uint32_t uuid ;
/*!< The UUID should be read according to the gattDbAttribute_t.uuidType member: for 2-byte and 4-byte␣
↪UUIDs, this contains the value of the UUID; for 16-byte UUIDs, this is a pointer to the allocated 16-byte␣
↪array containing the UUID. */
    uint8_t * pValue ;
/*!< Pointer to allocated value array. */
    uint16_t valueLength ;
/*!< Size of the value array. */
    uint16_t uuidType : 2;
/*!< Identifies the length of the UUID; the 2-bit values are interpreted according to the bleUuidType_t␣
↪enumeration. */
    uint16_t maxVariableValueLength : 10;
/*!< Maximum length of the attribute value array; if this is set to 0, then the attribute's length␣
↪(valueLength) is fixed and cannot be changed. */
} gattDbAttribute_t ;
```

Parent topic:*Prerequisites*

Non-Volatile Memory (NVM) access

The Bluetooth LE Host Stack implements an internal module responsible for managing device information. This module relies on accessing a Non-Volatile Memory module for storing and loading bonded devices data.

The application developers determine the NVM access mechanism through the definition of three functions and one variable. The functions must first pre-process the information and then perform standard NVM operations (erase, write, read). The declarations are as follows:

```
bleResult_t App_NvmErase
(
    uint8_t mEntryIdx
);
bleResult_t App_NvmRead
(
    uint8_t  mEntryIdx,
    void*    pBondHeader,
    void*    pBondDataDynamic,
    void*    pBondDataStatic,
    void*    pBondDataLegacy,
    void*    pBondDataDeviceInfo,
    void*    pBondDataDescriptor,
    uint8_t  mDescriptorIndex
);
bleResult_t App_NvmWrite
(
    uint8_t  mEntryIdx,
    void*    pBondHeader,
    void*    pBondDataDynamic,
    void*    pBondDataStatic,
    void*    pBondDataLegacy,
    void*    pBondDataDeviceInfo,
    void*    pBondDataDescriptor,
    uint8_t  mDescriptorIndex
);
```

The device information is divided into several components to ensure that even software wear leveling mechanisms can be used optimally. The components sizes are fixed (defined in *ble_constants.h*) and have the following meaning:

API pointer to bond component	Component size (*ble_constants.h*)	Description
pBondHeader: points to a bleBondIdentityHeaderBlob_t element	gBleBondIdentityHeaderSize_c	Bonding information which is sufficient to identify a bonded device.
pBondDataDynamic: points to a bleBondDataDynamicBlob_t element	gBleBondDataDynamicSize_c	Bonding information that might change frequently.
pBondDataStatic: points to a bleBondDataStaticBlob_t element	gBleBondDataStaticSize_c	Bonding information that is unlikely to change frequently.
pBondDataLegacy: points to a bleBondDataLegacyBlob_t element	gBleBondDataLegacySize_c	Stores legacy pairing bond information.
pBondDataDeviceInfo: points to a bleBondDataDeviceInfoBlob_t element	gBleBondDataDeviceInfoSize_c	Additional bonding information that can be accessed using the host stack API.
pBondDataDescriptor: points to a bleBondDataDescriptorBlob_t element	gBleBondDataDescriptorSize_c	Bonding information used to store one Client Characteristic Configuration Descriptor (CCCD).

The Bluetooth LE Host Stack handles the format of the bonding information. Therefore, application developers need not to take care of this aspect.

Each bonding data slot must contain one bonding header blob, one dynamic data blob, one static data blob, one data legacy blob, one device information blob, and an array of descriptor blobs equal to *gcGapMaximumSavedCccds_c.*

Note: *The application must define the* gcGapMaximumSavedCccds_c. *macro according to its requirement. The default value can be found in the* ble_constants.h *file.*)

A slot is uniquely identified by the *mEntryIdx* parameter.

A descriptor is uniquely identified by the pair *mEntryIdx - mDescriptorIndex*.

If one or more pointers passed as parameters are NULL, the read from or write to the corresponding blob of the bonding slot must be ignored. The erase function must clear the entire bonding data slot specified by the entry index.

Note:

When Advanced Secure Mode is chosen (gAppSecureMode_d is defined as 1 in app_preinclude.h), two additional application NVM functions are defined to handle local keys encrypted blob storage. Their declaration is:

```
bleResult_t App_NvmWriteLocalKeys
(
    uint8_t mEntryIdx,
    void* pLocalKey
)
bleResult_t App_NvmReadLocalKeys
(
    uint8_t mEntryIdx,
    void* pLocalKey
)
```

The functions write/read a structure of type bleLocalKeysBlob_t into/from NVM using a dedicated data set. The parameter mEntryIdx is 0 (local IRK is handled).

The format of the local keys blob nor about the generation and storage of the local keys is automatically handled in **BLE Connection Manager** (*BleConnManager_GenericEvent*). Therefore the application developer need not manage this aspect.

The current implementation of the aforementioned functions uses either the framework NVM module or a RAM buffer. Additional details about the NVM configuration and functionality can be found in the *Connectivity Framework Reference Manual.* See *References*.

To enable the NVM mechanism, ensure the following points:

- gAppUseNvm_d (in *app_preinclude.h*) is set to 1 and
- gUseNVMLink_d is set to 1 in the linker options of the toolchain.

Note:

- If gAppUseNvm_d is set to 0, then all bonding data is stored in the RAM and is accessible until reset or power cycle.
- If gAppUseNvm_d is set to 1, the default NVM module configurations are applied in the *app_preinclude.h* file.

Parent topic:*Prerequisites*

Bluetooth LE Host Stack Initialization and APIs

Initialization

The application developer is required to configure the Host Task as part of the Host Stack requirement. The task is the context for running all the Host layers (GAP, GATT, ATT, L2CAP, SM, GATTDB)

The prototype of the task function is located in the *ble_host_tasks.h* file:

```
void Host_TaskHandler(void * args);
```

It should be called with *NULL* as an argument in the task code from the application.

Application developers are required to define task events and queues as explained in RTOS Task Queues and Events.

If the Controller software runs on the same chip as the Host, the Controller task always has a higher priority than the Host task. The priority value of the Host Task can be configured through the *gHost_TaskPriority_c define* (by default set in *ble_host_task_config.h*). Note that changing this value can have a significant impact on the Bluetooth Low Energy stack.

Parent topic:*Bluetooth LE Host Stack Initialization and APIs*

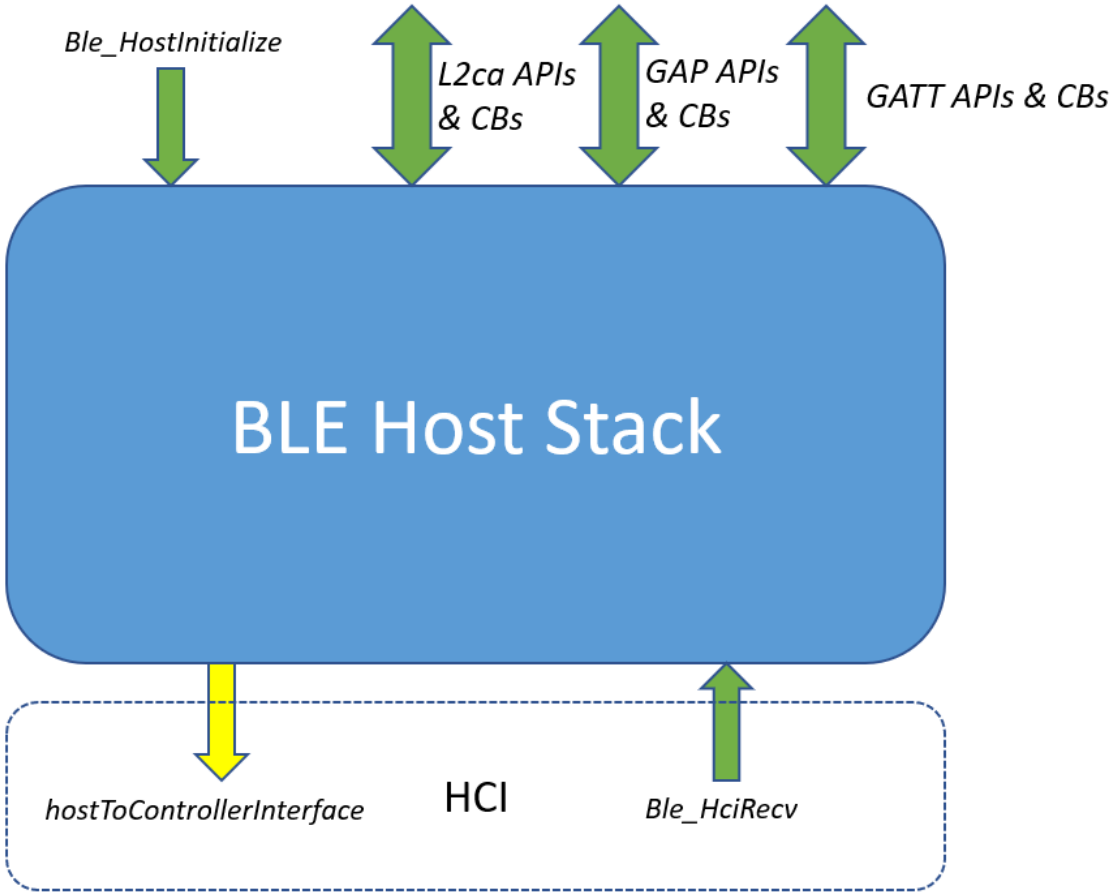
Main function to initialize the Bluetooth LE Host Stack

This Figure provides an overview of Bluetooth Low Energy Host Stack. When using the existing application common files, the startup task uses *BluetoothLEHost_AppInit()*, which is defined in *app_conn.h*. The function initializes all components related to the Bluetooth Low Energy application. It has the following prototype:

```
void BluetoothLEHost_AppInit(void);
```

The *BluetoothLEHost_AppInit()* function must be implemented by each application. It should register its generic event callback using *BluetoothLEHost_SetGenericCallback()* and initialize the Bluetooth LE Host Stack layer by calling *BluetoothLEHost_Init()*. The prototype for the *BluetoothLEHost_Init()* function is found in *app_conn.h* and is implemented in *app_conn.c*.

```
void BluetoothLEHost_Init
(
    appBluetoothLEInitCompleteCallback_t pCallback
);
```



BluetoothLEHost_Init takes as parameter a function to be called at the end of Bluetooth LE Host Stack initialization. In this callback, the application can register its callbacks with the Host layer, allocate timers, start services, and perform similar tasks. The callback should have a prototype as follows:

```
static void BluetoothLEHost_Initialized(void);
```

BluetoothLEHost_Init() is responsible for initializing the Host.

Initialize the Bluetooth LE Host Stack after platform setup is complete and all RTOS tasks have been started. The function that should be called for this purpose is located in the *ble_general.h* file and has the following prototype:

```
bleResult_t Ble_HostInitialize
(
    gapGenericCallback_t            genericCallback,
    hciHostToControllerInterface_t  hostToControllerInterface
);
```

Parent topic:*Bluetooth LE Host Stack Initialization and APIs*

HCI entry and exit points

The HCI entry point of the Host Stack is the second function located in the *ble_general.h* file:

```
void Ble_HciRecv
(
    hciPacketType_t packetType,
    void* pHciPacket,
    uint16_t packetSize
);
```

This is the function that the application must call to insert an HCI message into the Host.

An equivalent exists, to be used in ISR context:

```
bleResult_t Ble_HciRecvFromIsr
(
    hciPacketType_t     packetType,
    void*               pHciPacket,
    uint16_t            packetSize
);
```

Therefore, the *Ble_HciRecv* function and the *hostToControllerInterface* parameter of the *Ble_HostInitialize* function represent the two points that need to be connected to the LE Controller (see Bluetooth Low Energy Host Stack overview), either directly (if the Controller software runs on the same chip as the Host) or through a physical interface (for example, UART).

Parent topic:*Bluetooth LE Host Stack Initialization and APIs*

Bluetooth LE Host Stack libraries and API availability

All the APIs referenced in this document are available in the Central and Peripheral libraries. The support for Bluetooth 5.3 optional features such as Advertising, Advertising Extensions, GATT Caching, and EATT are provided in separate host libraries. They are distributed in a similar process as the legacy ones using GAP/GATT role support, which is described as follows.

For example, below are listed the full-featured libraries with complete support for both Central and Peripheral APIs, at GAP level.

- *lib_ble_OPT_host_cm33_iar.a* (for IAR projects)
- *lib_ble_OPT_host_cm33_gcc.a* (for MCUX projects)

These libraries include optional features implemented by the Bluetooth LE Host. For applications that need to use only the mandatory 5.3 Bluetooth LE and below features, the *lib_ble_host_cm33_iar.a* or *lib_ble_host_cm33_gcc.a* libraries can be used instead.

However, some applications may be targeted to memory-constrained devices and do not need the full support. In the interest of reducing code size and RAM utilization, optimized libraries are provided:

- *lib_ble_host_peripheral_cm33_iar.a/ lib_ble_host_peripheral_cm33_gcc.a* and
- *lib_ble_OPT_host_peripheral_cm33_iar.a / lib_ble_OPT_host_peripheral_cm33_gcc.a.*
  - Support only APIs for the GAP Peripheral and GAP Broadcaster roles
  - Support only APIs for the GATT Server role
- *lib_ble_host_central_cm33_iar.a* and *lib_ble_OPT_host_central_cm33_iar.a*
- *lib_ble_host_central_cm33_gcc.a* and *lib_ble_OPT_host_central_cm33_gcc.a*
  - Support only APIs for the GAP Central and GAP Observer roles
  - Support only APIs for the GATT Client role

If one attempts to use an API that is not supported (for instance, calling *Gap_Connect* with the *lib_ble_host_peripheral_cm33_iar.a* and *lib_ble_host_peripheral_cm33_gcc.a*), then the API returns the *gBleFeatureNotSupported_c* error code.

Similarly, if the API for OPT is used with a host library that does not have support for optional features, then *gBleFeatureNotSupported_c* is returned. For instance, calling *Gap_SetExtAdvertising* parameters with the *lib_ble_host_peripheral_cm33_iar.a* and *lib_ble_host_peripheral_cm33_gcc.a*) returns the exit code *gBleFeatureNotSupported_c*.

Note: See the *Bluetooth Low Energy Host Stack API Reference Manual* for explicit information regarding API support. Each function documentation contains this information in the Remarks section.

Parent topic:*Bluetooth LE Host Stack Initialization and APIs*

Synchronous and asynchronous functions

The vast majority of the GAP and GATT APIs are executed **asynchronously**. Calling these functions generates a message and places it in the Host Task message queue.

Therefore, the actual result of these APIs is signaled in **events** triggered by specific callbacks installed by the application. See the *Bluetooth Low Energy Host Stack API Reference Manual* for specific information about the events that are triggered by each API.

However, there are a few APIs which are executed immediately (**synchronously**). This is explicitly mentioned in the *Bluetooth Low Energy Host Stack API Reference Manual* in the *Remarks* section of each function documentation.

If nothing is mentioned, then the API is asynchronous.

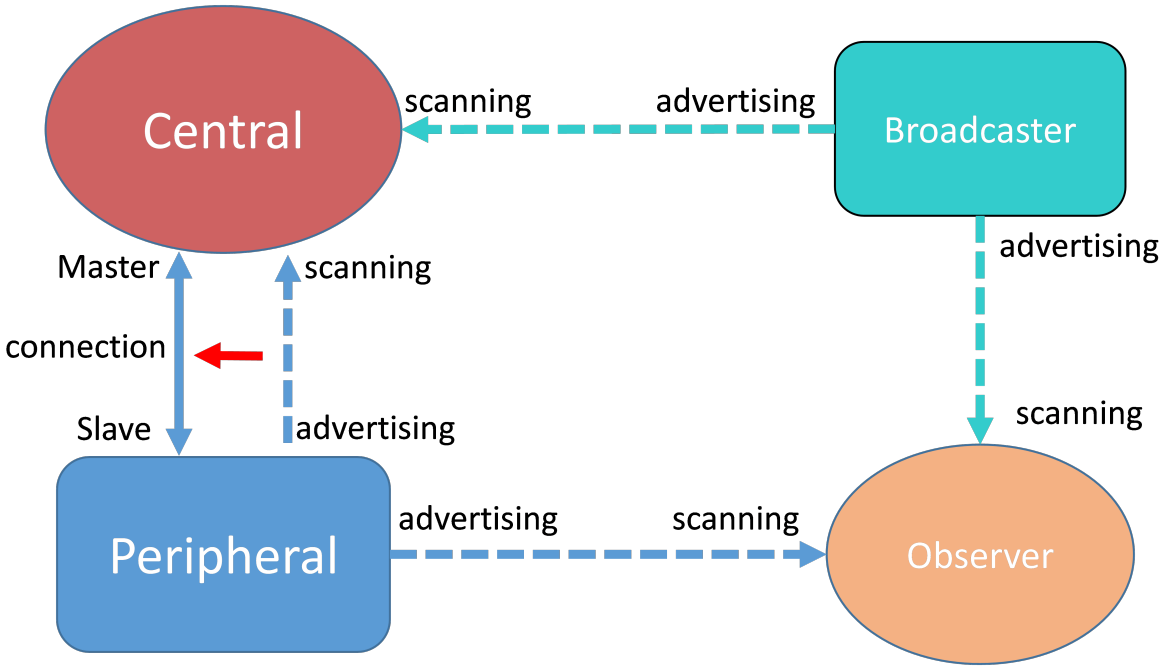
Parent topic:*Bluetooth LE Host Stack Initialization and APIs*

Radio TX Power level

The controller interface includes APIs that can be used to set the Radio TX Power to a different level than the default one.

The power level can be set differently for advertising and connection channels by calling the function *Controller_SetTxPowerLevelDbm()* with the channel parameter set to *gAdvTxChannel_c* or *gConnTxChannel_c*.

Parent topic:*Bluetooth LE Host Stack Initialization and APIs*



Generic Access Profile (GAP) Layer

The GAP layer manages connections, security, and bonded devices.

The GAP layer APIs are built on top of the Host-Controller Interface (HCI), the Security Manager Protocol (SMP), and the Device database.

GAP defines four possible roles that a Bluetooth Low Energy device may have in a Bluetooth Low Energy system:

- **Central**
  - Scans for advertisers (Peripherals and Broadcasters)
  - Initiates connection to Peripherals; Central at Link Layer (LL) level
  - Usually acts as a GATT Client, but can also contain a GATT Database itself
- **Peripheral**
  - Advertises and accepts connection requests from Central devices; LL Peripheral
  - Usually contains a GATT Database and acts as a GATT Server, but may also be a Client
- **Observer**
  - Scans for advertisers, but does not initiate connections; Transmit is optional
- **Broadcaster**
  - Advertises, but does not accept connection requests from Central devices; Receive is optional

The Figure illustrates the generic GAP topology.

Peripheral setup

The Peripheral starts advertising and waits for scan and connection requests from other Central devices.

Advertising

Before starting advertising, the advertising parameters should be configured. Otherwise, the following defaults are used.

```
#define gGapDefaultAdvertisingParameters_d \
{
   /* minInterval */      gGapAdvertisingIntervalDefault_c, \
   /* maxInterval */      gGapAdvertisingIntervalDefault_c, \
   /* advertisingType */ gConnectableUndirectedAdv_c, \
   /* addressType */      gBleAddrTypePublic_c, \
   /* peerAddressType */  gBleAddrTypePublic_c, \
   /* peerAddress */      {0U, 0U, 0U, 0U, 0U, 0U}, \
   /* channelMap */       (gapAdvertisingChannelMapFlags_t)gGapAdvertisingChannelMapDefault_c,  \
   /* filterPolicy */     gProcessAll_c \
}
```

To set different advertising parameters, a *gapAdvertisingParameters_t* structure should be allocated and initialized with defaults. Then, the necessary fields may be modified.

After that, the following function should be called:

```
bleResult_t Gap_SetAdvertisingParameters
(
    const gapAdvertisingParameters_t *      pAdvertisingParameters
);
```

The application should listen to the *gAdvertisingParametersSetupComplete_c* generic event.

Next, the advertising data should be configured and, if the advertising type supports active scanning, the scan response data should also be configured. If either of these is not configured, they are defaulted to empty data.

The function used to configure the advertising and/or scan response data is shown here:

```
bleResult_t Gap_SetAdvertisingData
(
  const gapAdvertisingData_t *      pAdvertisingData,
  const gapScanResponseData_t *     pScanResponseData
);
```

Either of the two pointers may be *NULL*, in which case they are ignored (the corresponding data is left as it was previously configured, or empty if it has never been set), but not both at the same time.

The application should listen to the *gAdvertisingDataSetupComplete_c* generic event.

After all the necessary setup is done, advertising may be started with this function:

```
bleResult_t Gap_StartAdvertising
(
    gapAdvertisingCallback_t advertisingCallback,
    gapConnectionCallback_t connectionCallback
);
```

The advertising callback is used to receive advertising events (advertising state changed or advertising command failed), while the connection callback is only used if a connection is established during advertising.

The connection callback is the same as the callback used by the Central when calling the *Gap_Connect* function.

When using the common application structure, the application can use the following API defined in *app_conn.h*:

```
bleResult_t BluetoothLEHost_StartAdvertising
(
    appAdvertisingParams_t    *pAdvParams,
    gapAdvertisingCallback_t pfAdvertisingCallback,
    gapConnectionCallback_t   pfConnectionCallback
);
```

The API goes through the steps of setting the advertising data and parameters. Events from the Host task are treated in the *App_AdvertiserHandler()* function, implemented in *app_advertiser.c*. To set the advertising parameters and data *BluetoothLEHost_StartAdvertising* requires a parameter of the following type:

```
typedef struct
appAdvertisingParams_tag
{
 gapAdvertisingParameters_t *pGapAdvParams; /*!< Pointer to the GAP advertising parameters */
 const gapAdvertisingData_t *pGapAdvData; /*!< Pointer to the GAP advertising data */
 const gapScanResponseData_t *pScanResponseData;
 /*!< Pointer to the scan response data */ } appAdvertisingParams_t;
```

If a Central initiates a connection to this Peripheral, the *gConnEvtConnected_c* connection event is triggered.

To stop advertising while the Peripheral has not yet received any connection requests, use this function:

```
bleResult_t Gap_StopAdvertising (void);
```

This function should not be called after the Peripheral enters a connection, as the advertising automatically stops in this case.

Parent topic: Peripheral setup

Pairing and bonding (peripheral)

After a connection has been established to a Central, the Peripheral's role regarding security is a passive one. It is the responsibility of the Central device to start the pairing process. In case, the devices have already bonded in the past, the Central encrypts the link using the shared LTK.

The Peripheral sends error responses (at ATT level) with proper error code if the Central attempts to access sensitive data without authenticating. Examples of such error responses are: Insufficient Authentication, Insufficient Encryption, Insufficient Authorization, and so on. Therefore, it indicates to the Central that it needs to perform security procedures.

All security checks are performed internally by the GAP module and the security error responses are sent automatically. All the application developer needs to do is register the security requirements.

First, when building the GATT Database (see *Creating GATT database*), the sensitive attributes should have the security built into their access permissions (for example, read-only / read with authentication / write with authentication / write with authorization, and so on.).

Second, if the GATT Database requires additional security besides that already specified in attribute permissions (for example, certain services require higher security in certain situations), the following function must be called:

```
bleResult_t Gap_RegisterDeviceSecurityRequirements
(
    const gapDeviceSecurityRequirements_t * pSecurity
);
```

The parameter is a pointer to a structure which contains a "device security setting" and service-specific security settings. All these security requirements are pointers to gapSecurityRequirements_t structures. The pointers that are to be ignored should be set to NULL.

Although the Peripheral does not initiate any kind of security procedure, it can inform the Central about its security requirements.

The informing is performed through the Peripheral Security Request packet at SMP level. To use it, the following GAP API is provided:

```
bleResult_t Gap_SendPeripheralSecurityRequest
(
    deviceId_t                  deviceId,
    const gapPairingParameters_t* pPairingParameters
);
```

The gapPairingParameters_t structure includes two important fields. The withBonding field indicates to the Central whether this Peripheral can bond and the securityModeAndLevel field informs about the required security mode and level that the Central should pair for. See Pairing and bonding (Central) for an explanation about security modes and levels, as defined by the GAP module.

This request expects no reply, nor any immediate action from the Central. The Central may easily choose to ignore the Peripheral Security Request.

If the two devices have bonded in the past, the Central proceeds directly to encrypting the link. If the bond was not made using LE Secure Connections, the Peripheral expects to receive a gConnEvtLongTermKeyRequest_c connection event. If the bond was made using LE Secure Connections, the Host provides the LTK automatically to the LE Controller.

When the devices have been previously pairing without using LE Secure Connections, along with the Peripheral's LTK, the EDIV (2 bytes) and RAND (8 bytes) values were also sent (their meaning is defined by the SMP). Therefore, before providing the key to the Controller, the application should check that the two values match with those received in the gConnEvtLongTermKeyRequest_c event. If they do, the application should reply with:

```
bleResult_t Gap_ProvideLongTermKey
(
    deviceId_t          deviceId,
    const uint8_t*      aLtk,
    uint8_t             ltkSize
);
```

The LTK size cannot exceed the maximum value of 16.

If the EDIV and RAND values do not match, or if the Peripheral does not recognize the bond, it can reject the encryption request with:

```
bleResult_t Gap_DenyLongTermKey
(
    deviceId_t deviceId
);
```

If LE SC Pairing was used then the LTK is generated internally by the Bluetooth LE Host Stack and it is not requested from the application during post-bonding link encryption. In this scenario, the application is only notified of the link encryption through the gConnEvtEncryptionChanged_c connection event.

If the devices are not bonded, the Peripheral should expect to receive the gConnEvtPairingRequest_c, indicating that the Central has initiated pairing.

If the application agrees with the pairing parameters (see Pairing and bonding (Central) for detailed explanations), it can reply with:

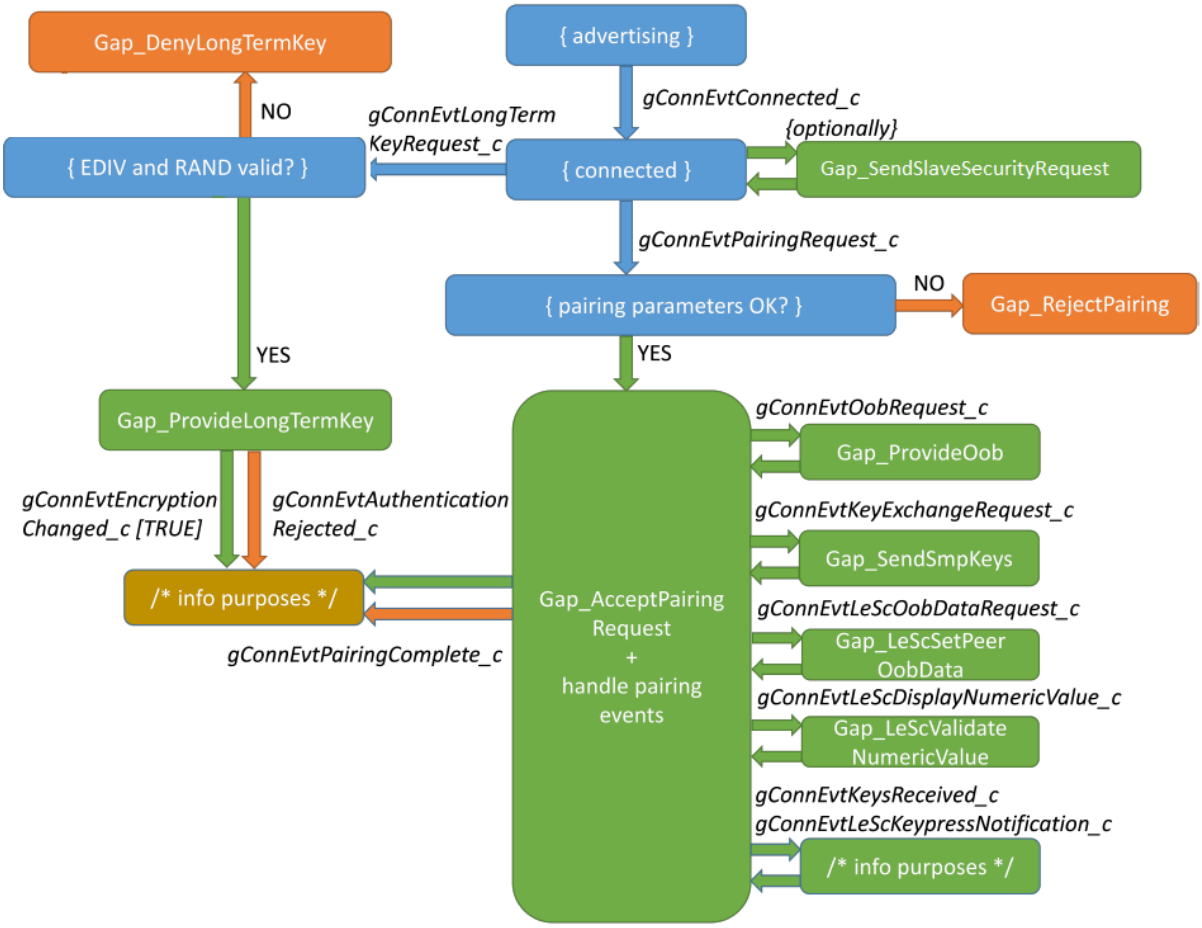
```
bleResult_t Gap_AcceptPairingRequest
(
    deviceId_t                      deviceId,
    const gapPairingParameters_t *    pPairingParameters
);
```

This time, the Peripheral sends its own pairing parameters, as defined by the SMP.

After sending this response, the application should expect to receive the same pairing events as the Central (see Pairing and bonding (Central)), with one exception: the gConnEvtPasskeyRequest_c event is not called if the application sets the Passkey (PIN) for pairing before the connection by calling the API:

```
bleResult_t Gap_SetLocalPasskey
(
    uint32_t passkey
);
```

This is done because, usually, the Peripheral has a static secret PIN that it distributes only to trusted devices. If, for any reason, the Peripheral must dynamically change the PIN, it can call the aforementioned function every time it wants to, before the pairing starts (for example, right before sending the pairing response with Gap_AcceptPairingRequest).



If the Peripheral application never calls Gap_SetLocalPasskey, then the gConnEvtPasskeyRequest_c event is sent to the application as usual.

The Peripheral can use the following API to reject the pairing process:

```
bleResult_t Gap_RejectPairing
(
deviceId_t                      deviceId,
gapAuthenticationRejectReason_t    reason
);
```

The reason should indicate why the application rejects the pairing. The value gLinkEncryptionFailed_c is reserved for the gConnEvtAuthenticationRejected_c connection event to indicate the link encryption failure rather than pairing failures. Therefore, it is not meant as a pairing reject reason.

The Gap_RejectPairing function may be called not only after the Pairing Request was received, but also during the pairing process. For example, when handling pairing events or asynchronously, if for any reason the Peripheral decides to abort the pairing, this function can be called. This also holds true for the Central. Figure illustrates the Peripheral pairing flow and lists the main APIs and events. Gap_RejectPairing can be called on any pairing event.

For both the Central and the Peripheral, bonding is performed internally and is not the application's concern. The gConnEvtPairingComplete_c event parameters inform the application if bonding has occurred.

Parent topic: Peripheral setup

Parent topic:*Generic Access Profile (GAP) Layer*

Central setup

Usually, a Central must start scanning to find Peripherals. When the Central has scanned a Peripheral it wants to connect to, it stops scanning and initiates a connection to that Peripheral. After the connection has been established, it may start pairing, if the Peripheral requires it, or directly encrypt the link, if the two devices have already bonded in the past.

Scanning

The most basic setup for a Central device begins with scanning, which is performed by the following function from *gap_interface.h*:

```
bleResult_t Gap_StartScanning
(
  const gapScanningParameters_t* pScanningParameters,
  gapScanningCallback_t scanningCallback,
  gapFilterDuplicates_t enableFilterDuplicates,
  uint16_t duration,
  uint16_t period
);
```

If the *pScanningParameters* pointer is NULL, the currently set parameters are used. If no parameters have been set after a device power-up, the standard default values are used:

```
#define gGapDefaultScanningParameters_d \
{ \
    /* type */              gScanTypePassive_c, \
    /* interval */          gGapScanIntervalDefault_d, \
    /* window */              gGapScanWindowDefault_d, \
    /* ownAddressType */    gBleAddrTypePublic_c, \
    /* filterPolicy */      gScanAll_c \
    /* scanning PHY */      gLePhy1MFlag_c\
}
```

The easiest way to define non-default scanning parameters is to initialize a *gapScanningParameters_t* structure with the above default and change only the required fields.

For example, to perform active scanning and only scan for devices in the Filter Accept List, the following code can be used:

```
gapScanningParameters_t scanningParameters = gGapDefaultScanningParameters_d;
scanningParameters.type = gScanTypeActive_c;
scanningParameters.filterPolicy = gScanWithFilterAcceptList_c;
Gap_StartScanning(&scanningParamters, scanningCallback, enableFilterDuplicates, duration, period);
```

When using the common application structure, the application can use the following API defined in *app_conn.h*:

```
bleResult_t BluetoothLEHost_StartScanning
(
    appScanningParams_t    *pAppScanParams,
    gapScanningCallback_t pfCallback
);
```

The API uses the *appScanningParams_t* structure, which is defined as follows:

```
typedef struct appScanningParams_tag
{
    gapScanningParameters_t *pHostScanParams;         /*!< Pointer to host scan structure */
    gapFilterDuplicates_t enableDuplicateFiltering;   /*!< Duplicate filtering mode */
    uint16_t duration;                                /*!< scan duration  */
    uint16_t period;                                  /*!< scan period  */
} appScanningParams_t;
```

The *scanningCallback* is triggered by the GAP layer to signal events related to scanning.

The most important event is the *gDeviceScanned_c* event, which is triggered each time an advertising device is scanned. This event data contains information about the advertiser:

```
typedef struct
{
    bleAddressType_t                addressType ;
    bleDeviceAddress_t              aAddress ;
    int8_t                         rssi ;
    uint8_t                         dataLength ;
    uint8_t*                        data ;
    bleAdvertisingReportEventType_t   advEventType ;
    bool_t                          directRpaUsed;
    bleDeviceAddress_t              directRpa;
    bool_t                          advertisingAddressResolved;
} gapScannedDevice_t;
```

If this information signals a known Peripheral that the Central wants to connect to, the latter must stop scanning and connect to the Peripheral.

To stop scanning, call this function:

```
bleResult_t Gap_StopScanning (void);
```

By default, the GAP layer is configured to report all scanned devices to the application using the *gDeviceScanned_c* event type. However, some use cases might require to perform specific GAP Discovery Procedures. In such use cases the advertising reports might require the filtering of Flags AD value from the advertising data. Other use cases require the Bluetooth LE Host Stack to automatically initiate a connection when a specific device has been scanned.

To enable filtering based on the Flags AD value or to set device addresses for automatic connections, the following function must be called before the scanning is started:

```
bleResult_t Gap_SetScanMode
(
    gapScanMode_t           scanMode,
    gapAutoConnectParams_t* pAutoConnectParams,
    gapConnectionCallback_t connCallback
);
```

The default value for the scan mode is *gDefaultScan_c*, which reports all packets regardless of their content and does not perform any automatic connection.

To enable Limited Discovery, the *gLimitedDiscovery_c* value must be used, while the *gGeneralDiscovery_c* value activates General Discovery.

To enable automatic connection when specific devices are scanned, the *gAutoConnect_c* value must be set, in which case the *pAutoConnectParams* parameter must point to the structure that holds the target device addresses and the connection parameters to be used by the Host for these devices.

If scanMode is set to *gAutoConnect_c*, connCallback must be set and is triggered by GAP to send the events related to the connection.

Parent topic: Central setup

Initiating and closing a connection

To connect to a scanned Peripheral, extract its address and address type from the *gDeviceScanned_c* event data, stop scanning, and call the following function:

```
bleResult_t Gap_Connect
(
const gapConnectionRequestParameters_t * pParameters,
gapConnectionCallback_t connCallback
);
```

When using the common application structure, the application can also use the following API defined in *app_conn.h*:

```
bleResult_t BluetoothLEHost_Connect
(
    gapConnectionRequestParameters_t*   pParameters,
    gapConnectionCallback_t             connCallback
);
```

An easy way to create the connection parameter structure is to initialize it with the defaults, then change only the necessary fields. The default structure is defined as shown here:

```
#define gGapDefaultConnectionRequestParameters_d \
{ \
    /* scanInterval */       gGapScanIntervalDefault_d, \
    /* scanWindow */          gGapScanWindowDefault_d, \
```

(continues on next page)

(continued from previous page)

```
    /* filterPolicy */       gUseDeviceAddress_c, \
    /* ownAddressType */     gBleAddrTypePublic_c, \
    /* peerAddressType */    gBleAddrTypePublic_c, \
    /* peerAddress */        { 0, 0, 0, 0, 0, 0 }, \
    /* connIntervalMin */    gGapDefaultMinConnectionInterval_d, \
    /* connIntervalMax */    gGapDefaultMaxConnectionInterval_d, \
    /* connLatency */        gGapDefaultConnectionLatency_d, \
    /* supervisionTimeout */ gGapDefaultSupervisionTimeout_d, \
    /* connEventLengthMin */ gGapConnEventLengthMin_d, \
    /* connEventLengthMax */ gGapConnEventLengthMax_d \
    /* initiatingPHYs     */ gLePhylMFlag_c \
}
```

In the following example, Central scans for a specific Heart Rate Sensor with a known address. When it finds it, it immediately connects to it.

```
static void BleApp_ScanningCallback
(
    gapScanningEvent_t *pScanningEvent
)
{
    switch (pScanningEvent->eventType)
    {
        case gDeviceScanned_c:
        {
            if (BleApp_CheckScanEvent(&pScanningEvent->eventData.scannedDevice))
            {
                gConnReqParams.peerAddressType = pScanningEvent->eventData.scannedDevice.addressType;
                FLib_MemCpy(gConnReqParams.peerAddress,
                        pScanningEvent->eventData.scannedDevice.aAddress,
                        sizeof(bleDeviceAddress_t));
                (void)Gap_StopScanning();
#if gAppUsePrivacy_d
                gConnReqParams.usePeerIdentityAddress =  pScanningEvent->eventData.scannedDevice.
↪advertisingAddressResolved;
#endif
                (void)BluetoothLEHost_Connect(&gConnReqParams, BleApp_ConnectionCallback);
            }
        }
        break;
}
```

The *connCallback* is triggered by GAP to send all events related to the active connection. It has the following prototype:

```
typedef void (* gapConnectionCallback_t )
(
    deviceId_t              deviceId,
    gapConnectionEvent_t * pConnectionEvent
);
```

The very first event that should be listened inside this callback is the *gConnEvtConnected_c* event. If the application decides to drop the connection establishment before this event is generated, it should call the following macro:

```
#define Gap_CancelInitiatingConnection()\
    Gap_Disconnect(gCancelOngoingInitiatingConnection_d)
```

This is useful, for instance, when the application chooses to use an expiration timer for the connection request.

Upon receiving the *gConnEvtConnected_c* event, the application may proceed to extract the nec-

essary parameters from the event data (*pConnectionEvent->event.connectedEvent*). The most important parameter to be saved is the *deviceId*.

The *deviceId* is a unique 8-bit, unsigned integer, used to identify an active connection for subsequent GAP and GATT API calls. All functions related to a certain connection require a *deviceId* parameter. For example, to disconnect, call this function:

```
bleResult_t Gap_Disconnect
(
    deviceId_t deviceId
);
```

Parent topic: Central setup

Pairing and bonding (Central)

After the user has connected to a Peripheral, use the following function to check whether this device has bonded in the past:

```
bleResult_t Gap_CheckIfBonded
(
    deviceId_t    deviceId,
    bool_t *      pOutIsBonded,
    uint8_t*      pOutNvmIndex
);
```

If it has, link encryption can be requested with:

```
bleResult_t Gap_EncryptLink
(
    deviceId_t      deviceId
);
```

If the link encryption is successful, the *gConnEvtEncryptionChanged_c* connection event is triggered. Otherwise, a *gConnEvtAuthenticationRejected_c*event is received with the *rejectReason* event data parameter set to *gLinkEncryptionFailed_c*.

On the other hand, if this is a new device (not bonded), pairing may be started as shown here:

```
bleResult_t Gap_Pair
(
    deviceId_t                      deviceId,
    const gapPairingParameters_t *    pPairingParameters
);
```

The pairing parameters are shown here:

```
typedef struct gapPairingParameters_tag {
    bool_t                      withBonding ;
    gapSecurityModeAndLevel_t      securityModeAndLevel ;
    uint8_t                     maxEncryptionKeySize ;
    gapIoCapabilities_t            localIoCapabilities ;
    bool_t                      oobAvailable ;
    gapSmpKeyFlags_t               centralKeys ;
    gapSmpKeyFlags_t               peripheralKeys ;
    bool_t                      leSecureConnectionSupported ;
    bool_t                      useKeypressNotifications ;
} gapPairingParameters_t;
```

The names of the parameters are self-explanatory. The *withBonding* flag should be set to *TRUE* if the Central must/wants to bond.

When Advanced Secure Mode is enabled, (*gAppSecureMode_d* id defined as *1* in *app_preinclude.h*), the security mode and level for pairing is automatically enforced as Mode 1

Level 4, and LE Secure Connection Supported is automatically enforced TRUE. Legacy pairing is not supported in this mode.

For the Security Mode and Level, the GAP layer defines them as follows:

- Security Mode 1 Level 1 stands for no security requirements.
- Except for Level 1 (which is only used with Mode 1), Security Mode 1 requires encryption, while Security Mode 2 requires data signing.
- Mode 1 Level 2 and Mode 2 Level 1 do not require authentication (in other words, they allow Just Works pairing, which has no MITM protection). Mode 1 Level 3 and Mode 2 Level 2 require authentication (must pair with PIN or OOB data, which provide MITM protection).
- Starting with Bluetooth specification 4.2, OOB pairing offers MITM protection only in certain conditions. The application must inform the stack if the OOB data exchange capabilities offer MITM protection via a dedicated API.
- Security Mode 1 Level 4 is reserved for authenticated pairing (with MITM protection) using a LE Secure Connections pairing method.
- If a pairing method is used but it does not offer MITM protection, then the pairing parameters must use Security Mode 1 level 2. If the requested pairing parameters are incompatible (for example, Security Mode 1 Level 4 without LE Secure Connections enabled), a gBleInvalidParameter_c status is returned by the security API functions: Gap_SetDefaultPairingParameters, Gap_SendPeripheralSecurityRequest, Gap_Pair and Gap_AcceptPairingRequest.

—	No security	No MITM protection	Legacy MITM protection	LE secure connections with MITM protection
Mode 1 (encryption) distributed LTK (EDIV+RAND) or generated LTK	**Level 1** no security	**Level 2** unauthenticated encryption	**Level 3** authenticated encryption	**Level 4** LE SC authenticated encryption

The *centralKeys* should have the flags set for all the keys that are available in the application. The IRK is mandatory if the Central is using a Private Resolvable Address. The LTK is provided by the Peripheral and should only be included if the Central intends on becoming a Peripheral in future reconnections (GAP role change).

The *peripheralKeys* should follow the same guidelines. The LTK is mandatory if encryption is to be performed, while the peer's IRK should be requested if the Peripheral is using Private Resolvable Addresses.

See table below for detailed guidelines regarding key distribution.

The first three rows are both guidelines for Pairing Parameters (*centralKeys* and *peripheralKeys*) and for distribution of keys with *Gap_SendSmpKeys*.

If LE Secure Connections Pairing is performed (Bluetooth Low Energy 4.2 and above), then the LTK is generated internally, so the corresponding bits in the key distribution fields from the pairing parameters are ignored by the devices.

The Identity Address is distributed if the IRK is also distributed (its flag has been set in the Pairing Parameters). Therefore, it can be "asked" only by asking for IRK (it does not have a separate flag in a *gapSmpKeyFlags_t* structure). Therefore, it is N/A.

The negotiation of the distributed keys is as follows:

- In the SMP Pairing Request (started by *Gap_Pair*), the Central sets the flags for the keys it wants to distribute (*centralKeys*) and receive (*peripheralKeys*).

	Central keys (Central)	Peripheral keys (Central)	Peripheral () keys	Central keys (peripheral)
Long Term Key (LTK)+EDIV +RAND	If it wants to be a peripheral in a future reconnection	If it wants encryption	If it wants encryption	If it wants to become a central in a future reconnection
Identity Resolving Key (IRK)	If it uses or intends to use private resolvable addresses	If a peripheral is using a private resolvable address	If it uses or intends to use private resolvable addresses	If a central is using a private resolvable address
Identity address	If it distributes the IRK	N/A	If it distributes the IRK	N/A

- The Peripheral examines the two distributions and must send an SMP Pairing Response (started by the *Gap_AcceptPairingRequest*) after performing any changes it deems necessary. The Peripheral is only allowed to set to 0 some flags that are set to 1 by the Central, but not the other way around. For example, it cannot request/distribute keys that were not offered/requested by the Central. If the Peripheral is adverse to the Central's distributions, it can reject the pairing by using the *Gap_RejectPairing* function.
- The Central examines the updated distributions from the Pairing Response. If it is adverse to the changes made by the Peripheral, it can reject the pairing (*Gap_RejectPairing*). Otherwise, the pairing continues and, during the key distribution phase (the *gConnEvtKeyExchangeRequest_c* event) only the final negotiated keys are included in the key structure sent with *Gap_SendSmpKeys*.
- For LE Secure Connections (both devices set the SC bit in the AuthReq field of the Pairing Request and Pairing Response packets), the LTK is not distributed. It is generated and the corresponding bit in the Initiator Key Distribution and Responder Key Distribution fields of the Pairing Response packet are set to 0.

If LE Secure Connections Pairing (Bluetooth LE 4.2 and above) is used, and OOB data needs to be exchanged, the application must obtain the local LE SC OOB Data from the Bluetooth LE Host Stack by calling the *Gap_LeScGetLocalOobData* function. The data is contained by the generic *gLeScLocalOobData_c* event.

The local LE SC OOB Data is refreshed in the following situations:

- The *Gap_LeScRegeneratePublicKey* function is called (the *gLeScPublicKeyRegenerated_c* generic event is also generated as a result of this API).
- The device is reset (which also causes the Public Key to be regenerated).

If the pairing continues, the following connection events may occur:

- **Request events**
  - *gConnEvtPasskeyRequest_c*: a PIN is required for pairing; the application must respond with the *Gap_EnterPasskey(deviceId, passkey).*
  - *gConnEvtOobRequest_c*: if the pairing started with the *oobAvailable* set to *TRUE* by both sides; the application must respond with the *Gap_ProvideOob(deviceId, oob).*
  - *gConnEvtKeyExchangeRequest_c*: the pairing has reached the key exchange phase; the application must respond with the *Gap_SendSmpKeys(deviceId, smpKeys).*
  - *gConnEvtLeScOobDataRequest_c*: the stack requests the LE SC OOB Data received from the peer (r, Cr and Addr); the application must respond with *Gap_LeScSetPeerOobData(deviceId, leScOobData).*
  - *gConnEvtLeScDisplayNumericValue_c*: the stack requests the display and confirmation of the LE SC Numeric Comparison Value; the application must respond with *Gap_LeScValidateNumericValue(deviceId, ncvValidated).*

- **Informational events**
  - *gConnEvtKeysReceived_c*: the key exchange phase is complete; keys are automatically saved in the internal device database and are also provided to the application for immediate inspection; application does not have to save the keys in NVM storage because this is done internally if *withBonding*was set to TRUE by both sides.
  - *gConnEvtAuthenticationRejected_c*: the peer device rejected the pairing; the *rejectReason* parameter of the event data indicates the reason that the Peripheral does not agree with the pairing parameters (it cannot be *gLinkEncryptionFailed_c* because that reason is reserved for the link encryption failure).
  - *gConnEvtPairingComplete_c*: the pairing process is complete, either successfully, or an error may have occurred during the SMP packet exchanges; note that this is different from the *gConnEvtKeyExchangeRequest_c* event; the latter signals that the pairing was rejected by the peer, while the former is used for failures due to the SMP packet exchanges.
  - *gConnEvtLeScKeypressNotification_c*: the stack informs the application that a remote SMP Keypress Notification has been received during Passkey Entry Pairing Method.

After the link encryption or pairing is completed successfully, the Central may immediately start exchanging data using the GATT APIs. Gap_RejectPairing may be called on any pairing event.

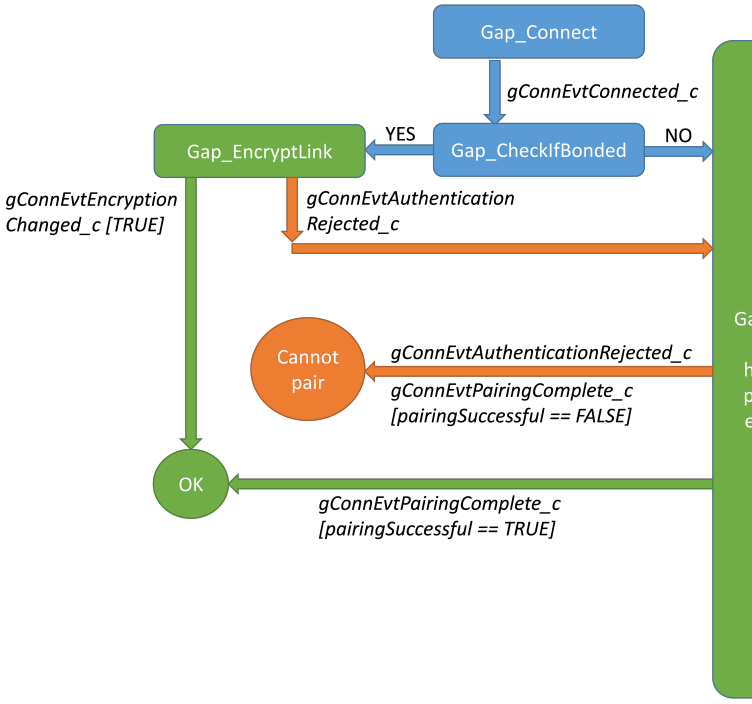


Figure 4. Central pairing flow – APIs and events.

Parent topic:*Generic Access Profile (GAP) Layer*

LE data packet length extension

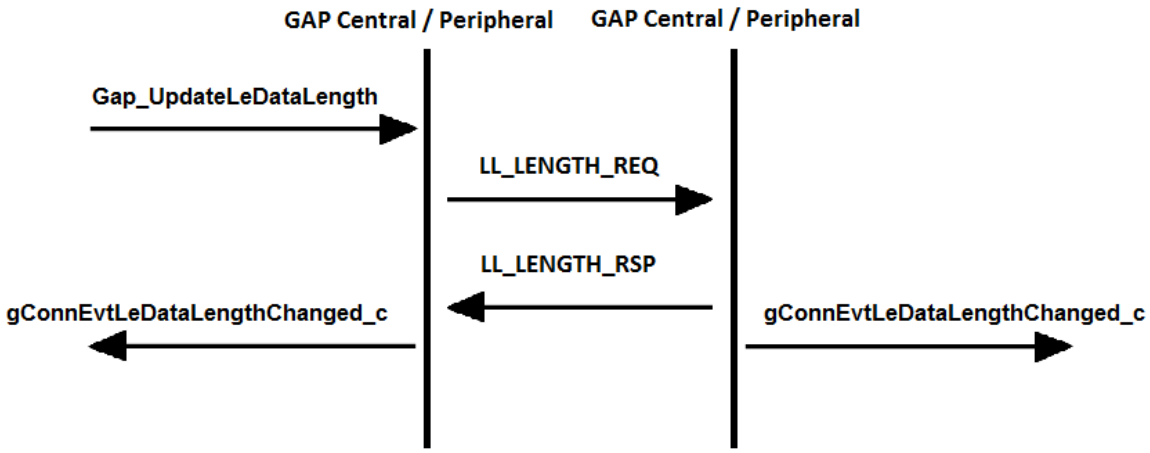
This new feature extends the maximum data channel payload length from 27 to 251 octets.

The length management is done automatically by the link layer immediately after the connection is established. The stack passes the default values for maximum transmission number of payload octets and maximum packet transmission time that the application configures at compilation time in *ble_config.h*:

```
#ifndef gBleDefaultTxOctets_c
```

(continues on next page)

(continued from previous page)



```
#define gBleDefaultTxOctets_c          0x00FB
#endif

#ifndef gBleDefaultTxTime_c
#define gBleDefaultTxTime_c            0x0848
#endif
```

The device can update the data length anytime, while in connection. The function that triggers this mechanism is the following:

```
bleResult_t Gap_UpdateLeDataLength
(
    deviceId_t          deviceId,
    uint16_t    txOctets,
    uint16_t    txTime
);
```

After the procedure executes, a *gConnEvtLeDataLengthChanged_c* connection event is triggered with the maximum values for number of payload octets and time to transmit and receive a link layer data channel PDU. The event is send event if the remote device initiates the procedure. This procedure is shown in Figure. **Figure 5. Data Length Update Procedure**

Parent topic:*Generic Access Profile (GAP) Layer*

Privacy feature

Introduction

Starting with Bluetooth 4.2, Privacy can be enabled either in the Host or in the Controller:

- **Host Privacy** consists of two use cases that are described in detail in the following sections. These are:
  - Random address generation - Periodically regenerating a random address (Resolvable or Non-Resolvable Private Address) inside the Host and then applying it into the Controller.
  - Random address resolution - Trying to resolve incoming RPAs using the IRKs stored in the bonded devices list. The address resolution is performed when a connection is established with a device or for the autoconnect scan. The advertising packets that have an RPA are not resolved automatically due to the high MCU processing that is required.

The random address resolution is performed by default by the Host whenever the Controller is not able to resolve an RPA. The Host performs random address generation only when Host Privacy is requested to be enabled. During random address generation, the advertising and scan operations, if active, are stopped and restarted. If errors occur during this process and the scan or advertising cannot be started, the application is notified through the corresponding event (gAdvertisingStateChanged_c, gExtAdvertisingStateChanged_c or gScanStateChanged_c)

- **Controller Privacy**, introduced by Bluetooth 4.2, consists of writing the local IRK in the Controller, together with all known peer IRKs, and letting the Controller perform hardware, fully automatic RPA generation and resolution. The Controller uses a Resolving List to store these entries. The size of the list is platform dependent and determined by gMaxResolvingListSize_c. For RPA resolution, the entries that do not fit in this list are processed by the Host to be resolved using the IRKs from Bonded Devices list.

Host Privacy can be enabled at any time. Controller Privacy should only be enabled while the device is not in the advertising, scanning or connection initiating state - otherwise the HCI LE Set Address Resolution Enable command will fail and privacy will not be considered as successfully enabled. Trying to enable one while the other is in progress generates a *gBleInvalidState_c* error. The same error is returned when trying to enable the same privacy type twice, or when trying to disable privacy when it is not enabled.

The recommended way of using Privacy is the Controller Privacy. However, enabling Controller Privacy requires at least a pair of local IRK and peer IRK, so this can only be enabled only after a pairing is performed with a peer and the IRKs are exchanged during the Key Distribution phase. When a device starts, if Privacy is required, the workflow is the following:

1. Enable Host Privacy using the local IRK.
2. Connect to a peer and perform pairing and bonding to exchange IRKs.
3. Disable Host Privacy.
4. Enable Controller Privacy using the local IRK and the peer IRK and peer identity address.

After enabling Host Privacy or Controller Privacy, the application must wait for the gHostPrivacyStateChanged_c or gControllerPrivacyStateChanged_c generic event and verify that privacy has been successfully enabled. Only then it is safe to proceed with setting advertising parameters (via the Gap_SetAdvertisingParameters or Gap_SetExtAdvertisingParameters APIs) or starting scanning (via the Gap_StartScanning API). Failure to do so could result in unwanted behavior, such as the device advertising or scanning with a public address.

Resolvable private addresses

A Resolvable Private Address (RPA) is a random address generated using an Identity Resolving Key (IRK). This address appears completely random to an outside observer, so a device may periodically regenerate its RPA to maintain privacy, as there is no correlation between any two different RPAs generated using the same IRK.

On the other hand, an IRK can also be used to resolve an RPA, in other words, to check if this RPA has been generated with this IRK. This process is called “resolving the identity of a device”. Whoever has the IRK of a device can always try to resolve its identity against an RPA.

For example, assume device A frequently changes its RPA using IRKA. At some point, A bonds with B. A must give B a way to recognize it in a subsequent connection when it (A) has a different address. To achieve this purpose, A distributes the IRKA during the Key Distribution phase of the pairing process. B stores the IRKA it received from A.

Later, B connects to a device X that uses RPAX. This address appears completely random, but B can try to resolve RPAX using IRKA. If the resolving operation is successful, it means that IRKA was used to generate RPAX, and since IRKA belongs to device A, it means that X is A. So B was able to recognize the identity of device X, but nobody else can do that since they do not have IRKA.

Parent topic: Introduction

Non-resolvable private addresses

A Non-Resolvable Private Address (NRPA) is a completely random address that has no generation pattern and therefore cannot be resolved by a peer.

A device that uses an NRPA that is changed frequently is impossible to track because each new address appears to belong to a new device.

Parent topic: Introduction

Multiple identity resolving keys

If a device bonds with multiple peers, all of which are using RPAs, it needs to store the IRK of each in order to be able to recognize them later (see previous section).

This means that whenever the device connects to a peer that uses an unknown RPA, it needs to try and resolve the RPA with each of the stored IRKs. If the number of IRKs is large, then this introduces a lot of computation.

Performing all these resolving operations in the Host can be costly. It is much more efficient to take advantage of hardware acceleration and enable the Controller Privacy.

Parent topic: Introduction

Parent topic: Privacy feature

Host privacy

To enable or disable Host Privacy, the following API may be used:

```
bleResult_t Gap_EnableHostPrivacy
(
    bool_t              enable,
    const uint8_t *     aIrk
);
```

When *enable* is set to TRUE, the *aIrk*parameter defines which type of Private Address to generate. If *aIrk* is NULL, then a new NRPA is generated periodically and written into the Controller. Otherwise, an IRK is copied internally from the *aIrk* address and it is used to periodically generate a new RPA.

The lifetime of the Private Address (NRPA or RPA) is a number of seconds contained by the *gGapHostPrivacyTimeout*external constant, which is defined in the *ble_config.c* source file. The default value for this is 900 (15 minutes).

When Host Privacy is enabled, the Host ignores the ownAddressType value for the advertising, scanning or connect parameters. It will always use the random address type in order to use the RPA configured in the Controller in the packets sent over the air.

As mentioned in the Introduction section, call this API for random address generation. For random address resolution there is no need to do so, it is performed by default against the bonded devices list.

Parent topic: Privacy feature

Controller privacy

To enable or disable Controller Privacy, the following API may be used:

```
bleResult_t Gap_EnableControllerPrivacy
(
    bool_t                          enable,
    const uint8_t *                   aOwnIrk,
    uint8_t                         peerIdCount,
    const gapIdentityInformation_t*      aPeerIdentities
);
```

When *enable* is set to TRUE, *aOwnIrk*parameter shall not be NULL, *peerIdCount* shall not be zero or greater than *gMaxResolvingListSize_c*, and *aPeerIdentities* shall not be NULL.

The IRK defined by *aOwnIrk* is used by the Controller to periodically generate a new Resolvable Private Address (RPA). The lifetime of the RPA is a number of seconds contained by the *gGapControllerPrivacyTimeout* external constant, which is defined in the *ble_globals.c* source file. The default value for this is 900 (15 minutes). The *gGapControllerPrivacyTimeoutMin* and *gGapControllerPrivacyTimeoutMax* external constants, also defined in *ble_globals.c*, contain the minimum and maximum values for the RPA lifetime if the Controller supports the Randomized RPA Timeout feature. The default value for both is 900 - same behavior as the non-randomized timeout.

The *aPeerIdentities* is an array of identity information for each bonded device. The identity information contains the device's identity address (public or random static address) and the device's IRK. This array can be obtained from the Host with the *Gap_GetBondedDevicesIdentityInformation*API.

Enabling Controller Privacy involves a quick sequence of commands to the Controller. When the sequence is complete, the *gControllerPrivacyStateChanged_c* generic event is triggered.

Privacy mode

In Bluetooth LE 5.0, the privacy mode has been introduced as an optional feature and is part of the GAP identity structure together with the address and address type. There are two modes: Network Privacy Mode (default) and Device Privacy Mode. These are valid only for Controller Privacy.

A device in network privacy mode only accepts packets from peers using private addresses.

A device in device privacy mode also accepts packets from peers using identity addresses, even if the peer had previously distributed the IRK. Private addresses are also accepted.

The privacy mode of a device is stored in NVM together with the IRK with a default value of Network. If the application wants to change this value it can extract the peer identities, modify the privacy mode from network to device and then enable Controller Privacy with the value.

To change the privacy mode of a device and make the change persistent, the user must call the following API:

```
bleResult_t Gap_SetPrivacyMode
(
    uint8_t nvmIndex,
    blePrivacyMode_t privacyMode
);
```

Parent topic: Controller privacy

Scanning and initiating

When a Central device is scanning while Controller Privacy is enabled, the Controller actively tries to resolve any RPA contained in the Advertising Address field of advertising packets. If any match is found against the peer IRK list, then the *advertisingAddressResolved* parameter from the scanned device structure is set to TRUE.

In this case, the *addressType* and *aAddress* fields no longer contain the actual Advertising Address as seen over the air, but instead they contain the identity address of the device whose

IRK was able to resolve the Advertising Address. In order to connect to this device, these fields shall be used to complete the *peerAddressType* and *peerAddress* fields of the connection request parameter structure, and the *usePeerIdentityAddress* field shall be set to TRUE.

If *advertisingAddressResolved* is equal to FALSE, then the advertiser is using a Public or Random Static Address, an NRPA, or a RPA that could not be resolved. Therefore, the connection to this device is initiated as if Controller Privacy was not enabled, by setting *usePeerIdentityAddress* to FALSE.

Parent topic: Controller privacy

Advertising

When a Peripheral starts advertising while Controller Privacy is enabled, the *ownAddressType* field of the advertising parameter structure is unused. Instead, the Controller always generates an RPA and advertises with it as Advertising Address.

If directed advertising is used, the Host only allows advertising to a device in the resolving list in order to be able to generate RPAs.

Parent topic: Controller privacy

Connected

When a device connects while Controller Privacy is enabled, the *gConnEvtConnected_c* connection event parameter structure contains more relevant fields than without Controller Privacy.

The *peerRpaResolved* field equals TRUE if the peer was using an RPA that was resolved using an IRK from the list. In that case, the *peerAddressType* and *peerAddress*fields contain the identity address of the resolved device, and the actual RPA used to create the connection (the RPA that a Central used when initiating the connection, or the RPA that the Peripheral advertised with) is contained by the *peerRpa* field.

The *localRpaUsed*field equals TRUE if the local Controller was automatically generating an RPA when the connection was created, and the actual RPA is contained by the *localRpa* field.

Setting PHY mode in a connection

In Bluetooth LE 5.0, the user is able to change the PHY mode in a connection through the Link Layer PHY Update Procedure and choose between default 1 Mbit/s, 2 Mbit/s high data rate or the coded S2 or S8 PHYs with 500 Kbps or 125 Kbps for longer range.

To set the PHY, the user can call:

```
bleResult_t Gap_LeSetPhy
(
    bool_t        defaultMode,
    deviceId_t    deviceId,
    uint8_t       allPhys,
    uint8_t       txPhys,
    uint8_t       rxPhys,
    uint16_t      phyOptions
);
```

There are two modes to use this API:

1. If defaultMode is set to TRUE, the user can call this function without being in a connection, i.e. provide a device ID. The PHY option is used by the Link Layer in the PHY response when a connection is created and the peer device initiates the PHY Update Procedure. The

application should listen for gLePhyEvent_c with the gPhySetDefaultComplete_c sub event type for the confirmation of the operation.

2. If defaultMode is set to FALSE, the user must also provide a valid device ID. The Host asks the Link Layer to initiate the PHY Update Procedure with the peer device using the provided parameters.

The application should listen for gLePhyEvent_c with the gPhyUpdateComplete_c sub event type for the confirmation of the update procedure to have ended. The result of the operation populates in the txPhy and rxPhy of the event. The result is from the negotiation of the local parameters and the peer PHY preferences.

To read the current PHY on a connection, call the following API:

```
bleResult_t Gap_LeReadPhy
(
    deviceId_t deviceId
);
```

The application should listen for gLePhyEvent_c with the gPhyRead_c sub event type for the confirmation of the operation. The txPhy and rxPhy indicate the current modes used in the connection.

Parent topic:*Generic Access Profile (GAP) Layer*

Data management of bonded devices

The Host handles the management of the bonding data without requiring application intervention. The application must provide the NVM write, read, and erase functions presented in Non-Volatile Memory (NVM) access. The Host creates bonds if bonding is required after the pairing.

The bonded data structure is presented below, together with the GAP APIs that access it, for most APIs require a connection to be established with the device in the bonded list, the others can be accessed any time using the NVM index.

1. Bond Header – identity address and address type that uniquely identify a device together with the IRK and privacy mode.
    - Gap_GetBondedDevicesIdentityInformation – for all bonds
2. Bond Data Dynamic - security counters for signed operations – managed by the stack
3. Bond Data Static – LTK, Rand, EDIV, security information for read and write authorizations
    - Gap_SaveKeys– NVM index
    - Gap_LoadKeys– NVM index
    - Gap_LoadEncryptionInformation - deviceId
    - Gap_Authorize – deviceId - GATT Server only
4. Bond Data Legacy - Legacy pair information
    - Gap_LoadEncryptionInformation - deviceId
5. Bond Data Device Info - custom peer information (service discovery data) and device name
    - Gap_SaveCustomPeerInformation - deviceId
    - Gap_LoadCustomPeerInformation - deviceId
    - Gap_SaveDeviceName - deviceId
    - Gap_GetBondedDeviceName – NVM index
6. Bond Data Descriptor List - configuration of indications and notifications for CCCD handles – GATT Server only
    - Gap_CheckNotificationStatus - deviceId

- Gap_CheckIndicationStatus- deviceId

However, there may be some cases when an application wants to manage this data to read data from a bonded device created by the Host, create a bond obtained out-of-band or update an existing bond. For this use case, two GAP APIs and a GAP event have been added.

1. **Load the Keys of a bonded device**.

   The user can call the following function to read the keys exchanged during pairing and stored by the Bluetooth LE Host Stack in the bond area when the pairing is complete.

   The application is informed of the NVM index through the gBondCreatedEvent_c sent by the stack immediately after the bond creation. The application is responsible for passing the memory in the pOutKeys OUT parameter to fill in the keys, if any of the keys are set to NULL, the stack does not fill that information. The pOutKeyFlags OUT parameter indicates to the application which of the keys were stored by the stack as not all of them may have been distributed during pairing.

   The pOutLeSc indicates if Bluetooth LE 4.2 LE Secure Connections Pairing was used, while the pOutAuth indicates if the peer device is authenticated for MITM protection. All these OUT parameters are recommended to be retrieved from the bond and added if later passed as input parameters for the save keys API.

   This function executes synchronously.

```
bleResult_t Gap_LoadKeys
(
    uint8_t             nvmIndex,
    gapSmpKeys_t*       pOutKeys,
    gapSmpKeyFlags_t*   pOutKeyFlags,
    bool_t*             pOutLeSc,
    bool_t*             pOutAuth
);
```

   The gapSmpKeys_t is the structure used during the key distribution phase, as well as in the gConnEvtKeysReceived_c event and is as follows. The difference is that the Bluetooth LE device address cannot be set to NULL neither when loading a bond or when creating one as it identifies the bonded device together with the NVM index.
   Table 3. 'gapSmpKeys_t' structure

Event Data	Data type	Data Description
cLtk-Size	uint8_t	Encryption Key Size filled by the stack. If aLtk is NULL, this is ignored.In Advanced Secure Mode, this should be the size of the LTK encrypted blob of 40 bytes.
aLtk	uint8_t*	Long Term (Encryption) Key or LTK encrypted blob if Advanced Secure Mode is enabled. NULL if LTK isnot distributed, else size is given by cLtk-Size
aIrk	uint8_t*	Identity Resolving Key. NULL if aIrk is not distributed.
cRand-Size	uint8_t	Size of RAND filled by the stack; usually equal to gcSmpMaxRandSize_c. IfaLtk is NULL, this is ignored.
aRand	uint8_t*	RAND value used to identify the LTK. If aLtk is NULL, this is ignored.
ediv	uint16_t	EDIV value used to identify the LTK. If aLtk is NULL, this is ignored.
ad-dressTy	bleAd-dress Type_t	Public or Random address.
aAd-dress	uint8_t*	Device Address. It cannot be NULL.

The structure for the GAP SMP Key Flags is the following:

Table 4. GAP SMP Key Flags

Flag Type	Description
gNoKeys_c	No key is available.
gLtk_c	Long-Term Key is available.
gIrk_c	Identity Resolving Key is available.

2. Save the Keys to create a bond or update an existing bonded device.

   The user can call the following function to create a bond on a device based on information obtained Out of Band. For instance, one can use the output of Gap_LoadKeys from the previous section. This can be useful in transferring a bond created by the stack after a pairing procedure or if the application wants to manipulate bonding data. The behavior of the stack remains the same, if the bonding is required after a pairing, the stack stores the bonding information if possible. In this case, the NVM index is passed to the application through gBondCreatedEvent_c.

   This function executes asynchronously, as the stack can create a bond during the execution. The application should listen for the previous mentioned event gBondCreatedEvent_c. The result of the function call is passed synchronously. However, if an asynchronous error has occurred during the actual save, it is passed to the application through the gInternalError_c event with a gSaveKeys_c error source.

   The stack creates a bond if the NVM index is free or update the keys from an NVM index if it stores a valid entry.

   The address from the GAP SMP Keys structure must not be NULL. If other members of the structure are NULL, they are ignored.

   LE SC flag indicates if Bluetooth LE 4.2 Secure Connections was used during pairing and Auth specifies if the peer is authenticated for MITM protection.

```
bleResult_t Gap_SaveKeys
(
    uint8_t                 nvmIndex,
    const gapSmpKeys_t*     pKeys,
    bool_t                  leSc,
    bool_t                  auth
);
```

3. Bond created event.

   A GAP event is added to the Bluetooth LE Generic Callback to inform the application of the NVM index whenever the stack creates a bond or when a Gap_SaveKeys request succeeds. The event is also generated if the NVM index was a valid occupied entry and only some of the keys in the bonded information have been updated.

   The NVM index is then used in the GAP APIs to save or load information from the bond.

Event Data	Data type	Data Description
nvmIndex	uint8_t	NVM index for the new created bond
addressType	bleAddressType_t	Public or Random (static) address of the bond
address	bleDeviceAddress_t	Address of the bond

Application removal of bonded devices data

The application can remove a bonded device from NVM. The bonded device cannot be deleted if it is in an active connection. The application can remove one or all bonds by calling the following synchronous GAP APIs:

- Gap_RemoveBond(uint8_t nvmIndex) – nvmIndex can be obtained via the Gap_CheckIfBonded API.
- Gap_RemoveAllBonds() - no connections should be active otherwise the call fails.

Removing a bonded device does not affect the controller address resolution state nor the contents of either the Controller Filter Accept List or the Controller Resolving List. If Controller Privacy is enabled, it remains so until it is disabled or the device is reset.

In a scenario where the user wants to remove a bonded device and all its effects on device behavior (Controller Filter Accept List, Controller Resolving List), the following operations should be executed:

- Gap_ClearFilterAcceptList or Gap_RemoveDeviceFromFilterAcceptList
  - Clear Controller Filter Accept List or clear a device from Filter Accept List.
- Gap_RemoveAllBonds or Gap_RemoveBond
  - All bonded devices are removed or one bonded device is removed from NVM.
- BleConnManager_DisablePrivacy
  - Controller Privacy is disabled, Controller Resolving List is cleared and address resolution is disabled. The device should not be advertising or scanning, otherwise this call fails.
- BleConnManager_EnablePrivacy
  - Called after the gControllerPrivacyStateChanged_c event is received, confirming Controller Privacy has been disabled. If not all bonds have been deleted, Controller Privacy is reenabled. In the absence of bonds, Host Privacy is enabled.

Parent topic:*Generic Access Profile (GAP) Layer*

Controller enhanced notifications

This section describes how the application can configure and monitor the notifications generated by the Bluetooth Controller when advertising, scan, or connection events occur. This feature is proprietary to NXP that is available on selected Controllers.

The user can choose between two options:

1. Enable notifications from the GAP layer and monitor GAP events in the GAP Generic Callback. The controller issues HCI vendor-specific events processed by the Bluetooth LE Host and presented to the application in the GAP Generic Callback.
2. Enable notifications from the Controller interface and monitor controller events in a user-defined Application Callback.
3. Combination of the above two options: configure feature at GAP layer and install an Application Callback through the Controller interface. After setting the callback, the HCI vendor-specific events are not issued and implicitly the GAP events. Instead, the user receives the notifications in the installed callback until setting the callback to NULL again if it wants to revert to GAP events.

- **GAP configuration:**

  The user should call the following function to enable various events from the mask or use Event None to disable the feature. The Device ID is valid only for connection events.

```
bleResult_t Gap_ControllerEnhancedNotification
(    uint16_t eventType,
   deviceId_t deviceId
);
```

The event type is a bitmask having the following options:
Table 5. Event types and their description

Event Type	Event Description
gNotifEventNone_c	No enhanced notification event enabled
gNotifConnEventOver_c	Connection event over
gNotifConnRxPdu_c	Connection RX PDU
gNotifAdvEventOver_c	Advertising event over
gNotifAdvTx_c	Advertising ADV transmitted
gNotifAdvScanReqRx_c	Advertising SCAN REQ RX
gNotifAdvConnReqRx_c	Advertising CONN REQ RX
gNotifScanEventOver_c	Scanning event over
gNotifScanAdvPktRx_c	Scanning ADV PKT RX
gNotifScanRspRx_c	Scanning SCAN RSP RX
gNotifScanReqTx_c	Scanning SCAN REQ TX
gNotifConnCreated_c	Connection created
gNotifChannelMatrix_c	Enable channel status monitoring
gNotifPhyReq_c	Phy Req Pdu ack received
gNotifConnChannelMapUpdate_c	Channel map update
gNotifConnInd_c	Connect indication
gNotifPhyUpdateInd_c	Phy update indication

After enabling events, the user should wait for a gControllerNotificationEvent_c GAP Generic Event in the GAP Generic Callback. The first event received should have the event type set to gNotifEventNone_c with a status of success confirming the selected event mask has been enabled. The same event types apply for both the GAP command and the GAP event. The structure for the Controller Notification event is the following:
Table 6. Controller Notification Event structure

Event Data	Data type	Data Description
eventType	bleNotificationEvent_t	Enhanced notification event type
deviceId	deviceId_t	Device id of the peer, valid for connection events
rssi	int8_t	RSSI, valid for RX event types
channel	uint8_t	Channel, valid for connection event over or Rx/Tx events
ce_counte	uint16_t	Connection event counter, valid for connection events only
status	bleResult_t	Status of the request to select which events to be enabled/disabled
timestamp	uint16_t	Timestamp in 625 µs slots, valid for Conn RX event and Conn Created event
adv_hand	uint8_t	Advertising Handle, valid for advertising events, if multiple ADV sets supported

- **Controller configuration:**

  The user should call the following function to enable various events from the mask or use Event None to disable the feature. The same event types apply as the GAP layer types. The connection handle is valid only for connection events.

```
bleResult_t Controller_ConfigureEnhancedNotification
(
    uint16_t eventType,
    uint16_t conn_handle
);
```

The event monitoring is done in a user-installed callback by calling:

```
bleResult_t Controller_RegisterEnhancedEventCallback
(
    bleCtrlNotificationCallback_t notificationCallback
);
```

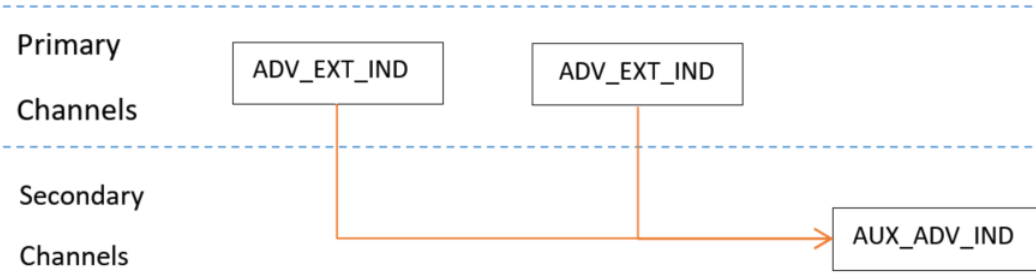
Where the types are the following:

```
typedef struct bleCtrlNotificationEvent_tag
{
    uint16_t event_type; /*! bleNotificationEventType_t */
    uint16_t conn_handle;
    uint8_t  rssi;
    uint8_t  channel_index;
    uint16_t conn_ev_counter;
    uint16_t timestamp;
    uint8_t  adv_handle;
} bleCtrlNotificationEvent_t;
typedef void (*bleCtrlNotificationCallback_t)
(
    bleCtrlNotificationEvent_t    *pNotificationEvent
);
```

The event structure is nearly identical as the GAP one, except there is no status as the function call executes synchronously.

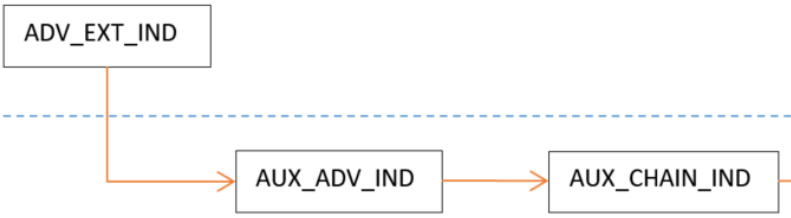
Table 7. 'bleCtrlNotificationEvent_tag' Event structure

Event Data	Data type	Data Description
event_type	bleNotificationEvent_t	Enhanced notification event type
conn_handle	uint16_t	Connection handle of the peer, valid for connection events
rssi	int8_t	RSSI, valid for RX event types
channel_index	uint8_t	Channel, valid for connection event over or Rx/Tx events
conn_ev_cou	uint16_t	Connection event counter, valid for connection events only
timestamp	uint16_t	Timestamp in 625 µs slots, valid for Conn RX event and Conn Created event
adv_handle	uint8_t	Advertising Handle, valid for advertising events, if multiple ADV sets supported



Parent topic:*Generic Access Profile (GAP) Layer*

Extended advertising



Starting with Bluetooth 5, the advertising channels are separated in primary advertising channels and secondary advertising channels:

1. Primary advertising channels
   - Use 3 legacy advertising channels 37, 38, and 39.
   - Can use either legacy 1M PHY or new LE Coded PHY.
   - PHY payload can vary from 6 to 37 bytes.
   - Packets on these channels are part of the advertising events.
2. Secondary advertising channels

- Use 37 channels, with the same channel index as the data channels.
- Can use any LE PHY, but the same PHY during an Extended Advertising Event.
- PHY payload can vary from 0 to 255 bytes.
- Auxiliary packets on these channels are part of the Extended Advertising Event that begins at the same time with the advertising event on primary channel and ends with the last packet on the secondary channel.

Extended advertising

Extended advertising – Multiple chains

An advertising data set is represented by advertising PDUs belonging together in an advertising event. Each set has different advertising parameters: PDU type, advertising interval, and PHY mode. The advertising data sets are identified by the Advertising SID (Set ID) field from the ADI – Advertising Data Info. Advertising data or Scan response data can be changed for each adverting data set and the random value of DID (Data ID) field is updated to differentiate between them.

Refer to Figure 1 and Figure 2.

Peripheral setup

This section describes the extended advertising GAP API. The application should not use both the extended and legacy API Refer to Scanning. If this requirement cannot be met, the application should at least wait for the generated events in the Advertising Callback prior to using the other API. That is, it is advisable to call legacy functions only after the event pertaining to an extended API is received, and vice versa. This GAP constraint can be considered an extension of the HCI constraint from the Bluetooth 5 specification: “A Host should not issue legacy commands to a Controller that supports the LE Feature (Extended Advertising)”.

The application configures extended advertising by going through the following states:

1. Set the extended advertising parameters by calling:

```
bleResult_t Gap_SetExtAdvertisingParameters
(
gapExtAdvertisingParameters_t* pAdvertisingParameters
);
```

It may use the default set of parameters *gGapDefaultExtAdvertisingParameters_d*. The application should wait for a *gExtAdvertisingParametersSetupComplete_c event* in the Generic Callback. Only one advertising set can be configured at a time. Comparing with the legacy *Gap_SetAdvertisingParameters* command, the new set of parameters is as follows.

Parameter	Description
SID	Value of the Advertising SID subfield in the ADI field of the PDU.
handle	Used to identify an advertising set. Possible values are 0x00 or 0x01 since the current implementation supports two advertising sets.
extAdvProperties	BIT0 - Connectable advertising
extAdvProperties	BIT1 - Scannable advertising
extAdvProperties	BIT2 - Directed advertising
extAdvProperties	BIT3 - High Duty Cycle Directed Connectable advertising (□3.75 ms Advertising Interval)
extAdvProperties	BIT4 - Use legacy advertising PDUs
extAdvProperties	BIT5 - Omit advertiser's address from all PDUs ("anonymous advertising")
extAdvProperties	BIT6 - Include TxPower in the extended header of the advertising PDU. If legacy advertising PDU types are being used (BIT4 = 1), permitted properties values are presented in the next table. If the advertising set already contains data, the type shall be one that supports advertising data and the amount of data shall not exceed 31 octets. If extended advertising PDU types are being used (BIT4 =0), then the advertisement shall not be both connectable and scannable. While high duty cycle directed connectable advertising (□ 3.75 ms advertising interval) shall not be used (BIT3 = 0).
txPowe	Maximum power level at which the advertising packets are to be transmitted, the Controller can choose any power level <= txPower. Value 127 to be used if Host has no preference.
primary-PHY	PHY for ADV_EXT_IND: LE 1 M or LE Coded
secondaı PHY	PHY for AUX_ADV_IND and periodic advertising: LE 1 M, LE 2 M or LE Coded. Ignored for legacy advertising
secondaı v-MaxS	Maximum advertising events that the Controller can skip before sending the AUX_ADV_IND packets on the secondary advertising channel. Higher values may result in lower power consumption. Ignored for legacy advertising
enableS can-ReqNo tifi-	Whether to enable notifications when scanning PDUs (SCAN_REQ, AUX_SCAN_REQ) are received. If enabled, the application is notified upon scan requests by gExtScanNotification_c events in the Advertising Callback

When using LE Coded PHY for advertising, the default coding scheme chosen by link layer is S=8 (125 kb/s data rate). To change the default coding scheme, the user has two options:

- At compile time by defining *mLongRangeAdvCodingScheme_c*, or
- At run time by calling the API *Controller_ConfigureAdvCodingScheme()*. In both cases, the value of the define or the parameter of the API has to be an appropriate value for primary and secondary PHYs as defined by the enumeration *advCodingScheme_tag* found in *controller_interface.h*. **API Controller_ConfigureAdvCodingScheme()**

EventType	PDU Type	Advertising Event Properties
Connectable and scannable undirected	ADV_IND	00010011b
Connectable directed (low duty cycle)	ADV_DIRECT_IND	00010101b
Connectable directed (high duty cycle)	ADV_DIRECT_IND	00011101b
Scannable undirected	ADV_SCAN_IND	00010010b
Non-connectable and Nonscannable undirected	ADV_NONCONN_INI	00010000b

2. Set the advertising data and/or scan response data by calling:

```
bleResult_t Gap_SetExtAdvertisingData
(
uint8_t handle,
gapAdvertisingData_t* pAdvertisingData,
gapScanResponseData_t* pScanResponseData
);
```

Note: Either of the pAdvertisingData or pScanResponseData parameters can be NULL, but not both. For extended advertising (BIT4 = 0) only one must be different than NULL – the scannable advertising bit (BIT1) indicates whether pAdvertisingData (BIT1 = 0) orpScanResponseData (BIT1 = 1) is accepted. The total amount of Advertising Data shall not exceed 1650 bytes. Application should wait for a *gExtAdvertisingDataSetupComplete_c* event in the Generic Callback.

3. Enable extended advertising by calling:

```
bleResult_t Gap_StartExtAdvertising
(
gapAdvertisingCallback_t advertisingCallback,
gapConnectionCallback_t connectionCallback,
uint8_t handle,
uint16_t duration,
uint8_t maxExtAdvEvents
);
```

When using the common application structure, the application can use the following API defined in *app_conn.h*:

```
bleResult_t BluetoothLEHost_StartExtAdvertising
(
    appExtAdvertisingParams_t *pExtAdvParams,
    gapAdvertisingCallback_t  pfAdvertisingCallback,
    gapConnectionCallback_t   pfConnectionCallback
);
```

The API goes through the steps of setting the advertising data and parameters. Events from the Host task are treated in the *App_AdvertiserHandler()* function, implemented in *app_advertiser.c*. To set the extended advertising parameters and data *BluetoothLEHost_StartExtAdvertising* a parameter of the following type:

```
typedef struct appExtAdvertisingParams_tag
{
    gapExtAdvertisingParameters_t *pGapExtAdvParams;
    gapAdvertisingData_t *pGapAdvData;
    gapScanResponseData_t *pScanResponseData;
    uint8_t                handle;
    uint16_t               duration;
    uint8_t                maxExtAdvEvents;
} appExtAdvertisingParams_t;
```

Advertising may be enabled for each previously configured advertising set, identified by the handle parameter. If duration is set to 0, advertising continues until the Host disables it, otherwise advertising is only enabled for this period (multiple of 10 ms). *maxExtAdvEvents* represent the maximum number of extended advertising events the Controller shall attempt to send prior to terminating the extended advertising, ignored if set to 0. Application should wait for a *gExtAdvertisingStateChanged_c* or a *gAdvertisingCommandFailed_c* event in the Advertising Callback.

4. Disable advertising by calling:

```
bleResult_t Gap_StopExtAdvertising
(
uint8_t handle
);
```

Application should wait for a *gExtAdvertisingStateChanged_c* or a *gAdvertisingCommandFailed_c* event in the Advertising Callback.

5. Remove the advertising set by calling:

```
bleResult_t Gap_RemoveAdvSet
(
uint8_t handle
);
```

Application should wait for a *gExtAdvertisingSetRemoveComplete_c* event in the Generic Callback.

Parent topic: Extended advertising

Central setup

The application configures the extended scanning by going through the following states:

1. Start scanning by calling:

```
bleResult_t Gap_StartScanning
(
const gapScanningParameters_t* pScanningParameters,
gapScanningCallback_t scanningCallback,
gapFilterDuplicates_t enableFilterDuplicates,
uint16_t duration,
uint16_t period
)
```

When using the common application structure, the application can use the following API defined in *app_conn.h*:

```
bleResult_t BluetoothLEHost_StartScanning
(
    appScanningParams_t   *pAppScanParams,
    gapScanningCallback_t pfCallback
);
```

The API starts scanning using the given parameters, which must have the following structure:

```
typedef struct appScanningParams_tag
{
    gapScanningParameters_t *pHostScanParams;          /*!< Pointer to host scan structure */
    gapFilterDuplicates_t enableDuplicateFiltering;    /*!< Duplicate filtering mode */
    uint16_t duration;                                          /*!< scan duration  */
    uint16_t period;                                            /*!< scan period  */
} appScanningParams_t;
```

Application may use the default set of parameters *gGapDefaultExtScanningParameters_d*. If the *pScanningParameters* pointer is NULL, the latest set of parameters are used. The *scanningPHYs* parameter indicates the PHYs on which the advertising packets should be received on the primary advertising channel. As a result, permitted values for the parameter are 0x01 (scan LE 1M), 0x04 (scan LE Coded) and 0x05 (scan both LE 1M and LE Coded). There are no strict timing rules for scanning, yet if both PHYs are enabled for scanning, the scan interval value must be large enough to accommodate two scan windows (interval >= 2 * window).

If the advertiser uses legacy advertising PDUs, the device may actively scan by sending a SCAN_REQ PDU to the advertiser on the LE 1M primary advertising channel (no secondary channel in legacy advertising). Respectively, if the advertiser uses extended advertising PDUs, the active scan operation takes place on the secondary advertising channel. After the device receives a scannable ADV_EXT_IND PDU on the primary advertising channel (PHY LE 1M or Coded), it starts listening for the AUX_ADV_IND PDU on the secondary advertising channel (PHY 1M, 2M or Coded). Once received, the device sends an AUX_SCAN_REQ to the advertiser. Next, an AUX_SCAN_RSP PDU should be received, containing the scan response data. Application should wait for a *gScanStateChanged_c* or a *gScanCommandFailed_c*in the Scanning Callback.

2. Collect information by waiting for *gDeviceScanned_c* (legacy advertising PDUs) or *gExtDeviceScanned_c* (extended advertising PDUs) event in the Scanning Callback. The *gExtDeviceScanned_c* event contains additional information pertaining to the extended received PDU, such as: primary PHY, secondary PHY, advertising SID, interval of the periodic advertising if enabled in the set.

   When using the common application structure, the application can use the following API defined in *app_conn.h*, to search the contents from *pData* in an advertising element:

   ```
   bool_t BluetoothLEHost_MatchDataInAdvElementList
   (
       gapAdStructure_t *pElement,
       void             *pData,
       uint8_t          iDataLen
   );
   ```

3. Stop scanning by calling the function below:

   ```
   bleResult_t Gap_StopScanning(void);
   ```

   Application should wait for a *gScanStateChanged_c* or a *gScanCommandFailed_c* in the Scanning Callback.

4. Connect to a device by calling the function below:

   ```
   bleResult_t Gap_Connect
   (
   const gapConnectionRequestParameters_t* pParameters,
   gapConnectionCallback_t connCallback
   );
   ```

   When using the common application structure, the following API can be used:

```
bleResult_t BluetoothLEHost_Connect
(
    gapConnectionRequestParameters_t*    pParameters,
    gapConnectionCallback_t              connCallback
);
```

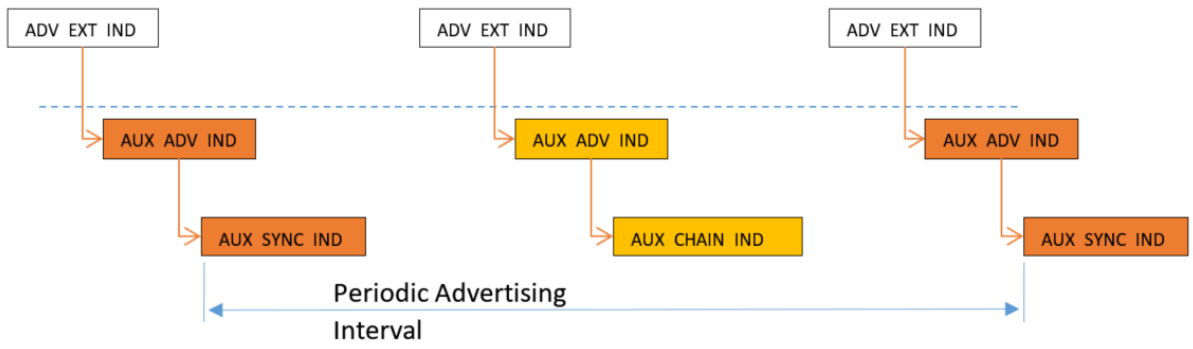
The *initiatingPHYs* parameter indicates the PHYs on which the advertising packets should be received on the primary advertising channel and the PHYs for which connection parameters have been specified. The parameter is a bitmask of PHYs: BIT0 = LE 1M, BIT1 = LE 2M and BIT2 = LE Coded. The Host may enable one or more initiating PHYs, but it must at least set one bit for a PHY allowed for scanning on the primary advertising channel, i.e., BIT0 for LE 1M PHY or BIT2 for LE Coded PHY.

If the advertiser uses legacy advertising PDUs, the device may connect by sending a CONNECT_IND PDU to the advertiser on the LE 1M primary advertising channel (no secondary channel in legacy advertising). On the other hand, if the advertiser uses extended advertising PDUs, the extended connect operation takes place on the secondary advertising channel. After the device receives a connectable ADV_EXT_IND PDU on the primary advertising channel (PHY LE 1M or Coded), it starts listening for the connectable AUX_ADV_IND PDU on the secondary advertising channel (PHY 1M, 2M or Coded). Once received, the device sends an AUX_CONNECT_REQ to the advertiser. Next, if AUX_CONNECT_RSP PDU is received, the device enters the Connection State in the Central role on the secondary advertising channel PHY.

Application should wait for a *gConnEvtConnected_c* event in the Connection Callback. If the channel selection algorithm #2 is used for this connection, then a *gConnEvtChanSelectionAlgorithm2_c* event is also generated.

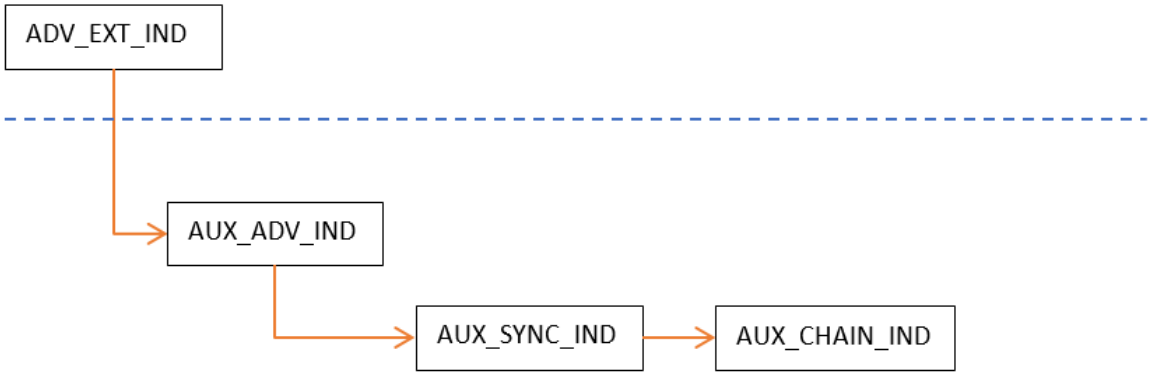
After the connection is successfully established, the application may choose to read the connection PHY by calling the *Gap_LeReadPhy* API. It may also opt to change the PHY of the connection by triggering a PHY Update Procedure using the *Gap_LeSetPhy API*. However, the Controller might not be able to perform the change if, in case the peer does not support the new requested PHY.

Parent topic: Extended advertising



Parent topic:*Generic Access Profile (GAP) Layer*

Periodic Advertising



Periodic channels are used for periodic broadcast between unconnected devices. A periodic channel is represented by a channel map and a set of hopping and timing parameters.

The set of channels is represented by the 37 data channels. A packet sent by an advertiser can also have a payload of up to 255 bytes and it can be sent on any LE PHY. Figure 1 and Figure 2.

Extended Advertising and Periodic Advertising combined

Periodic Advertising – Multiple chains

Peripheral Setup

1. First set the extended advertising parameters using Gap_SetExtAdvertisingParameters. The extended advertising type must be set to non-connectable and non-scannable.
2. Set the periodic advertising parameters using the same handle as in the previous command.

```
bleResult_t Gap_SetPeriodicAdvParameters
(
    gapPeriodicAdvParameters_t*     pAdvertisingParameters
);
```

   Wait for a *gPeriodicAdvParamSetupComplete_c*event in the generic callback.

3. Next, set the periodic advertising data by calling:

```
bleResult_t Gap_SetPeriodicAdvertisingData
(
    uint8_t                     handle,
    gapAdvertisingData_t*   pAdvertisingData,
    bool_t bUpdateDID
);
```

   pAdvertisingData cannot be NULL. If periodic advertising data must be empty, set *cNumAdStructures* to 0. Wait for a *gPeriodicAdvDataSetupComplete_c*event in the generic callback.

4. Start extended advertising using Gap_StartExtAdvertising.
5. Last, enable Periodic Advertising. Periodic advertising starts only after extended advertising is started.

```
bleResult_t Gap_StartPeriodicAdvertising
(
    uint8_t handle,
    bool_t  bIncludeADI
);
```

   Wait for a *gPeriodicAdvertisingStateChanged_c*event in the advertising callback.

Parent topic: Periodic Advertising

Central Setup

The application may decide to listen to periodic advertising by going through the following states:

1. [Optional] Add a known periodic advertiser to the periodic advertiser list held in the Controller by calling:

```
bleResult_t Gap_UpdatePeriodicAdvList
(
    gapPeriodicAdvListOperation_t operation,
    bleAddressType_t              addrType,
    uint8_t*                      pAddr,
    uint8_t                       SID
);
```

Wait for the *gPeriodicAdvListUpdateComplete_c* event in the Generic Callback.

2. Synchronize with a periodic advertiser by calling:

```
bleResult_t Gap_PeriodicAdvCreateSync
(
    gapPeriodicAdvSyncReq_t*    pReq,
);
```

pReq parameter *filterPolicy*can be set to *gUseCommandParameters_c* to synchronize with the given peer, or to *gUsePeriodicAdvList_c* to start synchronizing with all the devices in the previously populated periodic advertiser list.

Wait for the *gPeriodicAdvSyncEstablished_c* event and check the status. If scanning is not enabled at the time this command is sent, synchronization occurs after scanning is started. Synchronization remains pending until *gPeriodicAdvSyncEstablished_c*event is received. If synchronization was successful, the *syncHandle* is returned in this event.

3. Terminate the synchronization with the periodic advertiser by calling:

```
bleResult_t Gap_PeriodicAdvTerminateSync
(
    uint16_t syncHandle
);
```

To cancel a pending synchronization, the application should call *Gap_PeriodicAdvTerminateSync* with *syncHandle* set to the reserved value *gBlePeriodicAdvOngoingSyncCancelHandle* and wait for *gPeriodicAdvCreateSyncCancelled_c* event.

Otherwise, to terminate an already established sync with an advertiser, use the *syncHandle* value from the *gPeriodicAdvSyncEstablished_c* event and wait for a *gPeriodicAdvSyncTerminated_c* event.

Parent topic:*Generic Access Profile (GAP) Layer*

Periodic Advertising with Responses (PAwR)

This section describes the Central and Peripheral setup for Periodic Advertising with Responses (PAwR).

Central Setup

1. Start scanning using Gap_StartScanning. Wait for gPeriodicDeviceScannedV2_c events in the scanning callback.
2. Synchronize with a periodic advertiser by calling Gap_PeriodicAdvCreateSync. Wait for the gPeriodicAdvSyncEstablished_c event in the scanning callback. When PAwR is involved, this event includes additional information such as number of subevents, subevent interval, response slot delay and spacing,
3. Synchronize to a PAwR subevent by calling Gap_SetPeriodicSyncSubevent. This API instructs the Controller to sync with a subset of the subevents within a PAwR train identified by syncHandle (obtained after synchronizing with the PAwR train in the previous step).

```
bleResult_t Gap_SetPeriodicSyncSubevent ( uint16_t syncHandle, const␣
↪gapPeriodicSyncSubeventParameters_t* pParams );
```

Wait for the gPeriodicSyncSubeventComplete_c event.

4. Use Gap_SetPeriodicAdvResponseData to set data in the AD format which would be sent as a Periodic Advertising Response to the broadcaster.

```
bleResult_t Gap_SetPeriodicAdvResponseData ( uint16_t syncHandle, const␣
↪gapPeriodicAdvertisingResponseData_t* pData );
```

5. Optionally, the periodic advertiser may initiate a connection. If no connection callback was set on the scanner via APIs such as Gap_Connect or Gap_StartAdvertising/ Gap_StartExtAdvertising, one must be explicitly set. This is achieved by calling BluetoothLEHost_SetConnectionCallback (defined in app_conn.h), which in turn calls Gap_SetConnectionCallback.

```
void Gap_SetConnectionCallback ( gapConnectionCallback_t pfConnectionCallback );
```

Parent topic: Periodic Advertising with Responses (PAwR)

Peripheral Setup

1. First set the extended advertising parameters using Gap_SetExtAdvertisingParameters. The extended advertising type must be set to non-connectable and non-scannable.
2. Set the periodic advertising parameters with the same handle as in the previous command. Use the Gap_SetPeriodicAdvParametersV2 command. Compared to Gap_SetPeriodicAdvParameters, this command also configures parameters relevant to PAwR, such as the number of subevents and response slots as well as timing information.

```
bleResult_t Gap_SetPeriodicAdvParametersV2
  (gapPeriodicAdvParametersV2_t* pAdvertisingParameters);
```

Wait for a gPeriodicAdvParamSetupComplete_c event in the generic callback.

3. Start extended advertising using Gap_StartExtAdvertising.
4. Start periodic advertising using Gap_StartPeriodicAdvertising.
5. Wait for gPerAdvSubeventDataRequest_c events. These events are used by the Controller to indicate that it is ready to transmit one or more subevents and it is requesting the advertising data for these subevents. Upon receiving an event, use Gap_SetPeriodicAdvSubeventData to set the advertising data for specific subevents.

```
bleResult_t Gap_SetPeriodicAdvSubeventData
    (uint8_t advHandle, const gapPeriodicAdvertisingSubeventData_t* pData);
```

Wait for the gPeriodicAdvSetSubeventDataComplete_c event in the generic callback.

6. Wait for gPerAdvResponse_c events. These events contain responses sent by devices who are synchronized to the periodic advertising. They include data in the AD format.
7. Optionally, PAwR allows the advertising device to initiate a connection to one of the synchronized scanners. The connection can be initiated by calling Gap_ConnectFromPawr.

```
bleResult_t Gap_ConnectFromPawr
    (const gapConnectionFromPawrParameters_t* pParameters, gapConnectionCallback_t connCallback);
```

Parent topic: Periodic Advertising with Responses (PAwR)

Parent topic:*Generic Access Profile (GAP) Layer*

Encrypted Advertising Data

This section describes the Central and Peripheral setup for encrypted advertising data.

Central Setup

Use the Gap_DecryptAdvertisingData API to decrypt the contents of "Encrypted Advertising Data" (0x31) AD types included in scanned data.

```
bleResult_t Gap_DecryptAdvertisingData
    (uint8_t *pData, uint16_t dataLength, const uint8_t *pKey, const uint8_t *pIV, uint8_t *pOutput)
```

Parent topic: Encrypted Advertising Data

Peripheral Setup

Use the Gap_EncryptAdvertisingData API to obtain the encrypted advertising data, which can then be placed inside the "Encrypted Advertising Data" (0x31) AD type.

```
bleResult_t Gap_EncryptAdvertisingData
  ( const gapAdvertisingData_t *pAdvertisingData, const uint8_t *pKey, const uint8_t *pIV, uint8_t␣
↪*pOutput )
```

Parent topic: Encrypted Advertising Data

Parent topic:*Generic Access Profile (GAP) Layer*

L2CAP credit-based channels

The L2CAP layer, which is responsible for protocol multiplexing, segmentation, and reassembly operations, allows devices to communicate via connection-oriented channels. These channels use credit-based flow control, in which a device grants each peer a number of credits which the peer can use to send packets. The number of credits is decremented with every sent packet. A device can grant more credits to its peers over the duration of the connection.

Unlike the fixed L2CAP CIDs used by protocols such as ATT and SMP, credit-based channels use dynamically allocated CIDS (in the 0x0040-0xFFFF range). The CIDs are automatically allocated by the Bluetooth LE Host Stack.

The Bluetooth LE Host Stack supports both the Credit-based Flow Control Mode and the Enhanced Credit-based Flow Control Mode. In the Enhanced Credit-based Flow Control Mode, devices can open up to five channels in a single connect request/response exchange. Additionally, these channels can be later reconfigured with new MTU and MPS values. In the Credit-based Flow Control Mode, reconfiguration is not possible.

The first thing an application must do is register the control and data callbacks:

```
bleResult_t   L2ca_RegisterLeCbCallbacks
(
   l2caLeCbDataCallback_t      pCallback,
   l2caLeCbControlCallback_t   pCtrlCallback
);
```

The control callback receives events related to channel management such as connection, disconnection, received credits, reconfiguration, and so on.

The data callback receives the data which is being exchanged on the channel.

To use L2CAP credit-based channels, the application must register a PSM. The PSM is analogous to a TCP/UDP port. It is an identifier used to determine the upper layer protocol which is making use of the L2CAP channel. The dynamic PSM range is 0x0080-0x00FF. The number of PSMs supported by an application can be configured at compile time via the gL2caMaxLePsmSupported_c define. The following API must be called in order to register a PSM:

```
bleResult_t  L2ca_RegisterLePsm
(
  uint16_t     lePsm,
  uint16_t     lePsmMtu
);
```

The MTU configured via this API is used by every channel opened under the PSM, if the Credit-based Flow Control Mode is used. The minimum MTU is 23 and the maximum MTU is 65535.

When the Enhanced Credit-based Flow Control Mode is used, the MTU is specified at each connection request. In this mode, the minimum MTU is 64 and the maximum MTU is 65535.

The local MPS is not configurable by the application. It is set automatically by the Host Stack based on Controller capabilities. Usually, it will be 247.

A previously registered PSM can be deregistered:

```
bleResult_t L2ca_DeregisterLePsm
(
 uint16_t     lePsm
);
```

The number of credit-based channels that can be opened is configurable by the application via the gL2caMaxLeCbChannels_c define. This is the total number for all peers. To open a channel, the following API must be called:

```
bleResult_t L2ca_ConnectLePsm
(
  uint16_t     lePsm,
  deviceId_t   deviceId,
  uint16_t     initialCredits
);
```

To open up to five channels using Enhanced Credit-based Flow Control Mode, use this API:

```
bleResult_t  L2ca_EnhancedConnectLePsm
(
 uint16_t     lePsm,
 deviceId_t   deviceId,
 uint16_t     mtu,
 uint16_t     initialCredits,
 uint8_t      noOfChannels,
 uint16_t     *aCids
);
```

The connect APIs must be called by both the initiator and the responder (upon receiving the gL2ca_LePsmConnectRequest_c or gL2ca_LePsmEnhancedConnectRequest_c events in the application).

If the responder does not wish to accept the connection request, it can use the following APIs:

```
bleResult_t  L2ca_CancelConnection
   (
     uint16_t      lePsm,
     deviceId_t    deviceId,
    l2caLeCbConnectionRequestResult_t refuseReason
   );
bleResult_t L2ca_EnhancedCancelConnection
   (
   uint16_t lePsm,
   deviceId_t deviceId,
   l2caLeCbConnectionRequestResult_t refuseReason,
```

(continues on next page)

(continued from previous page)

```
    uint8_t noOfChannels,
    uint16_t *aCids
    );
```

When a channel has been successfully established, the gL2ca_LePsmConnectionComplete_c or gL2ca_LePsmEnhancedConnectionComplete_c events are received in the application.

To send data on a channel:

```
bleResult_t L2ca_SendLeCbData
(
  deviceId_t      deviceId,
  uint16_t        channelId,
  const uint8_t*  pPacket,
  uint16_t        packetLength
);
```

The Host Stack keeps track of the credits granted to peers for each channel and decrements them accordingly. When a peer's credit count reaches zero, the application is notified through the gL2ca_NoPeerCredits_c event and it can decide to send more credits to the peer for that channel:

```
bleResult_t L2ca_SendLeCredit
(
 deviceId_t     deviceId,
 uint16_t       channelId,
 uint16_t       credits
);
```

The application can also choose to be notified when the number of credits allocated to a peer for a certain channel is nearing 0, by setting the gL2caLowPeerCreditsThreshold_c macro to a non-zero value. When this limit is reached, the gL2ca_LowPeerCredits_c event is received and the application can choose to send more credits.

Similarly, when a device receives credits from a peer, the application is notified through the gL2ca_LocalCreditsNotification_c event. When the local device has used its last credit, it receives the same gL2ca_LocalCreditsNotification_c event with the localCredits field set to 0. The packet that could not be sent due to exhausting the credits remains queued in the Host Stack and it is sent automatically when the local device receives credits from the peer.

To improve application flow control, two notification-type events are implemented by the Host Stack:

- gL2ca_ChannelStatusChannelBusy_c
- gL2ca_ChannelStatusChannelIdle_c

When the application sends a packet using L2ca_SendLeCbData, it receives a gL2ca_ChannelStatusChannelBusy_c event in the L2CAP control callback when the Host Stack begins sending the packet. When the Host Stack has sent the packet, a gL2ca_ChannelStatusChannelIdle_c event is received. The application can choose to use this event as a signal that it is safe to send the next packet.

To disconnect a channel:

```
bleResult_t L2ca_DisconnectLeCbChannel
(
   deviceId_t  deviceId,
   uint16_t    channelId
);
```

As mentioned previously, channels which use the Enhanced Credit-based Flow Control Mode can be reconfigured. This is achieved via the API:

```
bleResult_t L2ca_EnhancedChannelReconfigure
(
    deviceId_t      deviceId,
    uint16_t        newMtu,
    uint16_t        newMps,
    uint8_t         noOfChannels,
    uint16_t        *aCids
);
```

The reconfiguration request is automatically accepted by the Host Stack if parameters are valid (as per the Bluetooth Core Spec v5.3, MTU cannot be lowered and MPS cannot be lowered for more than one channel). On the responder, the gL2ca_EnhancedReconfigureRequest_c is received by the application in case of a successful reconfiguration, informing it of the new channel parameters. On the initiator, the gL2ca_EnhancedReconfigureResponse_c is received, informing the application about the received response or a timeout.

Parent topic:*Generic Access Profile (GAP) Layer*

Enhanced ATT

The Enhanced ATT protocol allows concurrent transactions to be handled by the stack. The sequential transaction rule still exists when EATT is used, but its scope is now defined as being per instance of the Enhanced ATT Bearer. EATT transactions might execute in parallel if they are supported by distinct L2CAP channels, which use the Enhanced Credit Based Flow Control Mode (that is, distinct Enhanced ATT Bearers).

When using an Enhanced ATT Bearer, ATT MTU and L2CAP MTU are independently configurable and may be reconfigured during a connection. An increase to the MTU is allowed but reducing its size is not. Allowing MTU to be increased without needing to reestablish the connection has an advantage. It eliminates the risk of a second application using the stack, being unable to continue, due to the previously negotiated MTU being too small.

Enhanced ATT bearers are identified through Bearer Ids. Enhanced ATT Bearer Ids are assigned internally and have a valid range between 1 and 251. The Unenhanced ATT bearer is always available for a connected peer device and has the *BearerId 0*.

EATT Credits management

Credits for the L2CAP channels used by Enhanced ATT bearers may be managed internally if the autoCreditsMgmt parameter is set to TRUE in the Gap_EattConnectionRequest or Gap_EattConnectionAccept function call. Otherwise, the application is responsible for credits management.

If the application chooses to manage the credits of the L2CAP channels used as Enhanced ATT bearers, it should use the following function to send credits for a specified bearer to a peer device:

```
bleResult_t Gap_EattSendCredits
(
    deviceId_t  deviceId,
    bearerId_t  bearerId,
    uint16_t    credits
);
```

If the local credits or peer credits of the L2CAP channel used by an Enhanced ATT bearer reaches 0, agConnEvtEattBearerStatusNotification_c connection event is updated with a status value ofgEnhancedBearerSuspendedNoLocalCredits_c, or gEnhancedBearerNoPeerCredits_c respectively.

Parent topic: Enhanced ATT

EATT Connection establishment

In order to take advantage of the Enhanced ATT features, first a number of Enhanced Bearers should be opened for a connected peer device. For this, the function below may be used to create up to five Enhanced ATT bearers at a time:

```
bleResult_t Gap_EattConnectionRequest
(
    deviceId_t  deviceId,
    uint16_t    mtu,
    uint8_t     cBearers,
    uint16_t    initialCredits,
    bool_t      autoCreditsMgmt
);
```

The mtu parameter specifies the MTU for all the bearers to be established.

The cBearers parameter is used to specify the number of Enhanced ATT bearers to be opened, and should have a value between 1 and 5. The initialCredits parameter specifies the initial number of credits of the L2CAP credit based channels used as Enhanced ATT bearers.

The autoCreditsMgmt parameter is used to tell the Bluetooth LE Host Stack if it should manage L2CAP channel credits automatically. If set to TRUE the Bluetooth LE Host Stack automatically sends credits to a peer device when exhausted in chunks of initialCredits.

For example, to establish two Enhanced ATT bearers with a peer device the application may call the Gap_EattConnectionRequest as shown below:

```
bleResult_t result = Gap_EattConnectionRequest(peerDeviceId,
                                               64U,
                                               2U,
                                               3U,
                                               TRUE);
if (gBleSuccess_c != result)
{
    /* Treat error */
}
```

If an EATT Connection Request is received from a peer device it would be signaled through the gConnEvtEattConnectionRequest_c connection event of type gapEattConnectionRequest_t sent to the connection callback. The application should handle this event by calling Gap_EattConnectionAccept. The example below shows how an application may accept an incoming EATT Connection Request with the same MTU as requested by the peer device.

```
case gConnEvtEattConnectionRequest_c:
{
    gapEattConnectionRequest_t *pEattConnectionReq = &pConnectionEvent->eventData.
↪eattConnectionRequest;

    bleResult_t result = Gap_EattConnectionAccept(peerDeviceId,
                                                  TRUE,
                                                  pEattConnectionReq->mtu,
                                                  3U,
                                                  TRUE);

    if (gBleSuccess_c != result)
    {
        /* Treat error */
    }
}
break;
```

In case the localMtu specified when accepting a connection differs from the MTU requested by the peer device, the minimum of the two would become the MTU of the Enhanced Bearers.

After the Gap_EattConnectionRequest or Gap_EattConnectionAccept is called, for the result the

application should wait for the gConnEvtEattConnectionComplete_c connection event of type gapEattConnectionComplete_t shown below:

```
typedef struct {
    l2caLeCbConnectionRequestResult_t           status;
    uint16_t                                    mtu;
    uint8_t                                     cBearers;
    bearerId_t                                  aBearerIds[gGapEattMaxBearers];
} gapEattConnectionComplete_t;
```

If successful, the aBearerIds array contains the bearer ids, for the Enhanced ATT bearers established. These ids may be used with the GATT Enhanced APIs in order to trigger GATT procedures over Enhanced ATT bearers.

Parent topic: Enhanced ATT

EATT Bearer reconfiguration

One of the advantages of Enhanced ATT bearers over the Unenhanced ATT bearer is the ability to increase the MTU multiple times. To reconfigure the MTU and/or MPS of existing Enhanced ATT bearers, the Gap_EattReconfigureRequest should be used. If a mps value of 0 is given, the maximum available MPS value for that channel is used.

For example, in order to reconfigure the MTU of two bearers from 64 to 128 the application may call Gap_EattReconfigureRequest as shown below:

```
bleResult_t result = gBleSuccess_c;
bearerId_t aBearerIds[2] = {1U, 2U};
result = Gap_EattReconfigureRequest(peerDeviceId,
                                    128U,
                                    0U,
                                    2U,
                                    aBearerIds);
if (gBleSuccess_c != result)
{
    /* Treat error */
}
```

The application should monitor the gConnEvtEattChannelReconfigureResponse_c connection event of type gapEattReconfigureResponse_t for the result.

The procedure triggered by Gap_EattReconfigureRequest updates only the local MTU. The ATT_MTU for Enhanced ATT bearers is the minimum of the MTU values of the two devices.

Parent topic: Enhanced ATT

EATT Bearer disconnection

Individual Enhanced ATT bearers can be disconnected by calling the Gap_EattDisconnect API as shown below:

```
bleResult_t result = gBleSuccess_c;
result = Gap_EattDisconnect(peerDeviceId, bearerId);
if (gBleSuccess_c != result)
{
    /* Treat error */
}
```

The application should look for a connection event of type gEnhancedBearerDisconnected_c in the connection callback.

Parent topic: Enhanced ATT

Parent topic:*Generic Access Profile (GAP) Layer*

HCI Logging and Debug Keys

To facilitate debugging, the Bluetooth LE Host Stack can make use of HCI packet logging and security debug keys. This section describes how to configure and use these features.

Debug Keys

Debug keys are used during the pairing process to allow developers to decrypt and analyze Bluetooth LE traffic. When debug keys are enabled, the stack uses predefined key material instead of generating random keys, making it possible to monitor and inspect encrypted communications for debugging purposes. To use the Bluetooth LE Core Specification-defined debug keys for pairing, the application must set the gSecLibUseBleDebugKeys_d configuration macro to 1 in app_preinclude.h. It is sufficient to configure this setting on only one of the two connected devices. Bluetooth LE packet analyzers should be able to correctly decrypt communication.

HCI Packet Logging (BTSNOOP)

To configure HCI packet logging via the BTSNOOP protocol, the following steps must be performed:

- Enable the BTSNOOP debug framework module in the project configuration file (prj.conf) via west:

```
CONFIG_MCUX_COMPONENT_middleware.wireless.framework.dbg.sbtsnoop=y
CONFIG_MCUX_COMPONENT_middleware.wireless.framework.dbg.sbtsnoop.port.nxp_ble=y
```

- Generate the project.
- Set the SERIAL_BTSNOOP configuration macro to 1 in app_preinclude.h.
- Refer to BTSNOOP Module Documentation for details on how to retrieve logs.

Generic Attribute Profile (GATT) Layer

The GATT layer contains the APIs for discovering services and characteristics and transferring data between devices and is built on top of the Attribute Protocol (ATT).

The Attribute Protocol (ATT) transfers data between Bluetooth Low Energy devices on a dedicated L2CAP channel (channel ID 0x04).

As soon as a connection is established between devices, the GATT APIs are readily available. No initialization is required because the L2CAP channel is automatically created.

To identify the GATT peer instance, the same *deviceId* value from the GAP layer (obtained in the *gConnEvtConnected_c*connection event) is used.

There are two GATT roles that define the two devices exchanging data over ATT:

- GATT Server – the device that contains a GATT Database, which is a collection of services and characteristics exposing meaningful data. Usually, the Server responds to *requests* and *commands* sent by the Client. However, it can be configured to send data on its own through *notifications*and *indications*.
- GATT Client – the “active” device that usually sends *requests* and *commands* to the Server to *discover* Services and Characteristics on the Server’s Database and to exchange data.

There is no fixed rule deciding which device is the Client and which one is the Server. Any device may initiate a request at any moment. Therefore, it temporarily acts as a Client, at which the peer device may respond, provided it has the Server support and a GATT Database.

Often, a GAP Central acts as a GATT Client to discover Services and Characteristics and obtain data from the GAP Peripheral, which usually has a GATT database. Many standard Bluetooth Low

Energy profiles assume that the Peripheral has a database and must act as a Server. However, this is by no means a general rule.

Client APIs

A Client can configure the ATT MTU, discover Services and Characteristics, and initiate data exchanges.

All the functions have the same first parameter: a *deviceId* which identifies the connected device whose GATT Server is targeted in the GATT procedure. This is necessary because a Client may be connected to multiple Servers at the same time.

First, however, the application must install the necessary callbacks.

Installing client callbacks

There are three callbacks that the Client application must install.

Client procedure callback

All the procedures initiated by a Client are asynchronous. They rely on exchanging ATT packets over the air.

To be informed of the procedure completion, the application must install a callback with the following signature:

```
typedef void (* gattClientProcedureCallback_t )
(
    deviceId_t              deviceId,
    gattProcedureType_t     procedureType,
    gattProcedureResult_t   procedureResult,
    bleResult_t             error
);
```

For EATT, the following signature should be used:

```
typedef void (*gattClientEnhancedProcedureCallback_t)
(
   deviceId_t deviceId,
   bearerId_t bearerId,
   gattProcedureType_t procedureType,
   gattProcedureResult_t procedureResult,
   bleResult_t error
);
```

To install this callback, the following function must be called:

```
bleResult_t GattClient_RegisterProcedureCallback
(
    gattClientProcedureCallback_t callback
);
```

The EATT procedure callback should be installed using the following API:

```
bleResult_t GattClient_RegisterEnhancedProcedureCallback
(
 gattClientEnhancedProcedureCallback_t callback
);
```

The *procedureType* parameter can be used to identify the procedure that was started and has reached completion. Only one procedure would be active at a given moment. Trying to start another procedure while a procedure is already in progress returns the error *gGattAnotherProcedureInProgress_c*.

The *procedureResult* parameter indicates whether the procedure completes successfully or an error occurs. In the latter case, the *error* parameter contains the error code.

```
void gatt ClientProcedureCallback
(
    deviceId_t              deviceId,
    gattProcedureType_t     procedureType,
    gattProcedureResult_t   procedureResult,
    bleResult_t             error
)
{
    switch (procedureType)
    {
        /* ... */
    }
}
GattClient_RegisterProcedureCallback(gattClientProcedureCallback);
```

Parent topic: Installing client callbacks

Notification and indication callbacks

When the Client receives a notification from the Server, it triggers a callback with the following prototype:

```
typedef void (* gattClientNotificationCallback_t )
(
    deviceId_t      deviceId,
    uint16_t        characteristicValueHandle,
    uint8_t *       aValue,
    uint16_t        valueLength
);
```

The *deviceId* identifies the Server connection (for multiple connections at the same time). The *characteristicValueHandle* is the attribute handle of the Characteristic Value declaration in the GATT Database. The Client must have discovered it previously to be able recognize it.

For EATT, the following signature should be used:

```
typedef void (*gattClientEnhancedNotificationCallback_t)
 ( deviceId_t deviceId,
   bearerId_t bearerId,
   uint16_t characteristicValueHandle,
   uint8_t* aValue,
   uint16_t valueLength );
```

The callback must be installed with:

```
bleResult_t GattClient_RegisterNotificationCallback
(
    gattClientNotificationCallback_t callback
);
```

Very similar definitions exist for indications.

The EATT notification callback should be installed using the following API:

```
bleResult_t GattClient_RegisterEnhancedNotificationCallback
(
 gattClientEnhancedNotificationCallback_t callback
)
```

When receiving a notification or indication, the Client uses the *characteristicValueHandle* to identify which Characteristic was notified. The Client must be aware of the possible Characteristic

Value handles that can be notified/indicated at any time, because it has previously activated them by writing its CCCD (see Reading and writing characteristic descriptors).

When the Client receives a multiple value notification from the Server, it triggers a callback with the following prototype:

```
typedef void (*gattClientMultipleValueNotificationCallback_t)
(
    deviceId_t      deviceId,
    /*!< Device ID identifying the active connection. */
    uint8_t* aHandleLenValue,
    /*!< The array of handle, value length, value tuples. */
    uint32_t totalLength
    /*!< Value array size. */
);
```

The callback must be installed with:

```
bleResult_t GattClient_RegisterMultipleValueNotificationCallback
(
    gattClientMultipleValueNotificationCallback_t callback
);
```

When using EATT, the following callback prototype and registration APIs should be used:

```
typedef void (*gattClientEnhancedMultipleValueNotificationCallback_t)
( deviceId_t deviceId,
    /*!< Device ID identifying the active connection. */
  bearerId_t bearerId,
   /*!< Bearer ID identifing the Enhanced ATT bearer used. */
  uint8_t* aHandleLenValue,
   /*!< The array of handle, value length, value tuples. */
  uint32_t totalLength      /*!< Value array size. */
 );
```

Parent topic: Client APIs

MTU exchange

A radio packet sent over the Bluetooth Low Energy contains a maximum of 27 bytes of data for the L2CAP layer. The L2CAP header is 4 bytes long, including the Channel ID. Therefore, all layers above L2CAP, including ATT and GATT, can only send 23 bytes of data in a radio packet (as per *Bluetooth 4.1 Specification for Bluetooth Low Energy*). This specification also sets the default length of an ATT packet (also called *ATT_MTU*) to 23. The ATT packet length is set to this value to maintain a logical mapping between radio packets and ATT packets.

Note: This number is fixed and cannot be increased in Bluetooth Low Energy 4.1.

Therefore, any ATT request fits in a single radio packet. If the layer above ATT wishes to send more than 23 bytes of data, the data must be fragmented into smaller packets and multiple ATT requests issued.

Despite this setting, the ATT protocol allows devices to increase the ATT_MTU, only if both can support it. Increasing the ATT_MTU has only one effect: the application does not have to fragment long data. However, it can send more than 23 bytes in a single transaction. The fragmentation is moved on to the L2CAP layer. Over the air though, there would still be more than one radio packet sent.

If the GATT Client supports a larger than default MTU, it must start an MTU exchange as soon as it connects to any server. During the MTU exchange, both devices would send their maximum MTU to the other, and the minimum of the two is chosen as the new MTU.

Consider an example where the Client supports a maximum ATT_MTU of 250, and the server supports a maximum value of 120 for the same attribute. For this case, after MTU exchange, both devices must set the new ATT_MTU value equal to 120.

To initiate the MTU exchange, call the following function from *gatt_client_interface.h*:

```
bleResult_t result = GattClient_ExchangeMtu(deviceId, mtu);
if (gBleSuccess_c != result)
{
    /* Treat error */
}
```

When having the role of a GATT Client, the value of the maximum supported *ATT_MTU* of the local device is given as a parameter to the GattClient_ExchangeMtu API. On the GATT Server side, the application configures this value via the gcGattServerMtu_c variable that exists in the file ble_globals.c. The minimum of these two values is chosen as the new MTU for the connection.

When the exchange is complete, the *gGattProcExchangeMtu_c* procedure type triggers the Client callback.

```
void gattClientProcedureCallback
(
    deviceId_t deviceId,
    gattProcedureType_t procedureType,
    gattProcedureResult_t procedureResult,
    bleResult_t error
)
{
    switch (procedureType)
    {
        /* ... */
        case gGattProcExchangeMtu_c:
            if (gGattProcSuccess_c == procedureResult)
            {
                /* To obtain the new MTU */
                uint16_t newMtu;
                bleResult_t result = Gatt_GetMtu(deviceId, &newMtu);
                if (gBleSuccess_c == result)
                {
                    /* Use the value of the new MTU */
                    (void) newMtu;
                }
            }
            else
            {
                /* Handle error */
            }
            break;
        /* ... */
    }
}
```

Note: The Exchange MTU procedure is only available for the unenhanced/legacy bearer. For procedures sent on enhanced bearers, the upper layer must use provided **L2CAP APIs** to create dedicated L2CAP channels. Each channel has its own MTU value specified upon creation, which can also be reconfigured later.

Parent topic: Client APIs

Service and characteristic discovery

There are multiple APIs that can be used for Discovery. The application may use any of them, according to its necessities.

All of the following APIs have an enhanced counterpart of the form *GattClient_Enhanced[procedure]*. A *bearerId*parameter was added to specify on which bearer the transaction should take place. A value of *0* for the bearer Id identifies the Unenhanced ATT bearer. Values higher than *0* are used to identify the Enhanced ATT bearer used for the ATT procedure.

Discover all primary services

The following API can be used to discover all the Primary Services in a Server's database:

```
bleResult_t GattClient_DiscoverAllPrimaryServices
(
    deviceId_t          deviceId,
    gattService_t *     aOutPrimaryServices,
    uint8_t             maxServiceCount,
    uint8_t *           pOutDiscoveredCount
);
```

The *aOutPrimaryServices* parameter must point to an allocated array of services. The size of the array must be equal to the value of the *maxServiceCount* parameter, which is passed to make sure the GATT module does not attempt to write past the end of the array if more Services are discovered than expected.

The *pOutDiscoveredCount* parameter must point to a static variable because the GATT module uses it to write the number of Services discovered at the end of the procedure. This number is less than or equal to the *maxServiceCount*.

If there is equality, it is possible that the Server contains more than *maxServiceCount* Services, but they could not be discovered as a result of the array size limitation. It is the application developer's responsibility to allocate a large enough number according to the expected contents of the Server's database.

In the following example, the application expects to find no more than 10 Services on the Server.

```
#define mcMaxPrimaryServices_c 10
static gattService_t primaryServices[mcMaxPrimaryServices_c];
uint8_t mcPrimaryServices;
bleResult_t result = GattClient_DiscoverAllPrimaryServices
(
    deviceId,
    primaryServices,
    mcMaxPrimaryServices_c,
    &mcPrimaryServices
);
if (gBleSuccess_c != result)
{
    /* Treat error */
}
```

The operation triggers the Client Procedure Callback when complete. The application may read the number of discovered services and each service's handle range and UUID.

```
void gattClientProcedureCallback
(
    deviceId_t              deviceId,
    gattProcedureType_t     procedureType,
    gattProcedureResult_t   procedureResult,
    bleResult_t             error
)
{
    switch (procedureType)
    {
```

(continues on next page)

(continued from previous page)

```
        /* ... */
        case gGattProcDiscoverAllPrimaryServices_c:
            if (gGattProcSuccess_c == procedureResult)
            {
                /* Read number of discovered services */
                PRINT( mcPrimaryServices );
                /* Read each service's handle range and UUID */
                for (int j = 0; j < mcPrimaryServices; j++)
                {
                    PRINT( primaryServices[j]. startHandle );
                    PRINT( primaryServices[j]. endHandle );
                    PRINT( primaryServices[j]. uuidType );
                    PRINT( primaryServices[j]. uuid );
                }
            }
            else
            {
                /* Handle error */
                PRINT( error );
            }
            break;
        /* ... */
    }
}
```

Parent topic: Service and characteristic discovery

Discover primary services by UUID

To discover only Primary Services of a known type (Service UUID), the following API can be used:

```
bleResult_t GattClient_DiscoverPrimaryServicesByUuid
(
    deviceId_t          deviceId,
    bleUuidType_t       uuidType,
    const bleUuid_t *   pUuid,
    gattService_t *     aOutPrimaryServices,
    uint8_t             maxServiceCount,
    uint8_t *           pOutDiscoveredCount
);
```

The procedure is very similar to the one described in Discover all primary services. The only difference is this time we are filtering the search according to a Service UUID described by two extra parameters: *pUuid* and *uuidType*.

This procedure is useful when the Client is only interested in a specific type of Services. Usually, it is performed on Servers that are known to contain a certain Service, which is specific to a certain profile. Therefore, most of the times the search is expected to find a single Service of the given type. As a result, only one structure is usually allocated.

For example, when two devices implement the Heart Rate (HR) Profile, an HR Collector connects to an HR Sensor and may only be interested in discovering the Heart Rate Service (HRS) to work with its Characteristics. The following code example shows how to achieve this. Standard values for Service and Characteristic UUIDs, as defined by the Bluetooth SIG, are located in the *ble_sig_defines.h* file.

```
static gattService_t heartRateService;
static uint8_t mcHrs;
bleResult_t result = GattClient_DiscoverPrimaryServicesByUuid
(
    deviceId,
```

(continues on next page)

(continued from previous page)

```
    gBleUuidType16_c,             /* Service UUID type */
    gBleSig_HeartRateService_d,   /* Service UUID */
    &heartRateService,            /* Only one HRS is expected to be found */
    1,
    &mcHrs
   /* Will be equal to 1 at the end of the procedure
    if the HRS is found, 0 otherwise */

);
if (gBleSuccess_c != result)
{
    /* Treat error */
}
```

In the Client Procedure Callback, the application should check if any Service with the given UUID was found and read its handle range (also perhaps proceed with Characteristic Discovery within that service range).

```
void gattClientProcedureCallback
(
    deviceId_t deviceId,
    gattProcedureType_t procedureType,
    gattProcedureResult_t procedureResult,
    bleResult_t error
)
{
    switch (procedureType)
    {
        /* ... */
        case gGattProcDiscoverPrimaryServicesByUuid_c:
            if (gGattProcSuccess_c == procedureResult)
            {
                if (1 == mcHrs)
                {
                    /* HRS found, read the handle range */
                    PRINT( heartRateService. startHandle );
                    PRINT( heartRateService. endHandle );
                }
                else
                {
                    /* HRS not found! */
                }
            }
            else
            {
                /* Handle error */
                PRINT( error );
            }
            break;
        /* ... */
    }
}
```

Parent topic: Service and characteristic discovery

Discover included services

Discover all primary services shows how to discover Primary Services. However, a Server may also contain Secondary Services, which are not meant to be used standalone and are usually included in the Primary Services. The inclusion means that all the Secondary Service's Characteristics may be used by the profile that requires the Primary Service.

Therefore, after a Primary Service has been discovered, the following procedure may be used to discover services (usually Secondary Services) included in it:

```
bleResult_t GattClient_FindIncludedServices
(
    deviceId_t          deviceId,
    gattService_t *     pIoService,
    uint8_t             maxServiceCount
);
```

The service structure that *pIoService* points to must have the *aIncludedServices* field linked to an allocated array of services, of size *maxServiceCount*, chosen according to the expected number of included services to be found. This is the application's choice, usually following profile specifications.

Also, the service's range must be set (the *startHandle* and *endHandle* fields), which may have already been done by the previous Service Discovery procedure (as described in Discover all primary services and Discover primary services by UUID).

The number of discovered included services is written by the GATT module in the *cNumIncludedServices* field of the structure from *pIoService*. Obviously, a maximum of *maxServiceCount* included services is discovered.

The following example assumes the Heart Rate Service was discovered using the code provided in Discover primary services by UUID.

```
/* Finding services included in the Heart Rate Primary Service */
gattService_t * pPrimaryService = &heartRateService;
#define mxMaxIncludedServices_c 3
static gattService_t includedServices[mxMaxIncludedServices_c];
/* Linking the array */
pPrimaryService-> aIncludedServices = includedServices;
bleResult_t result = GattClient_FindIncludedServices
(
    deviceId,
    pPrimaryService,
    mxMaxIncludedServices_c
);
if (gBleSuccess_c != result)
{
    /* Treat error */
}
```

When the Client Procedure Callback is triggered, if any included services are found, the application can read their handle range and their UUIDs.

```
void gattClientProcedureCallback
(
    deviceId_t deviceId,
    gattProcedureType_t procedureType,
    gattProcedureResult_t procedureResult,
    bleResult_t error
)
{
    switch (procedureType)
    {
        /* ... */
        case gGattProcFindIncludedServices_c:
            if (gGattProcSuccess_c == procedureResult)
            {
                /* Read included services data */
                PRINT( pPrimaryService-> cNumIncludedServices );
                for (int j = 0; j < pPrimaryService-> cNumIncludedServices ; j++)
```

(continues on next page)

(continued from previous page)

```
            {
                PRINT( pPrimaryService-> aIncludedServices [j]. startHandle );
                PRINT( pPrimaryService-> aIncludedServices [j]. endHandle );
                PRINT( pPrimaryService-> aIncludedServices [j]. uuidType );
                PRINT( pPrimaryService-> aIncludedServices [j]. uuid );
            }
        }
        else
        {
            /* Handle error */
            PRINT( error );
        }
        break;
    /* ... */
  }
}
```

Parent topic: Service and characteristic discovery

Discover all characteristics of a service

The main API for Characteristic Discovery has the following prototype:

```
bleResult_t GattClient_DiscoverAllCharacteristicsOfService
(
  deviceId_t          deviceId,
  gattService_t *     pIoService,
  uint8_t             maxCharacteristicCount
);
```

All required information is contained in the service structure pointed to by *pIoService*, most importantly being the service range (*startHandle* and *endHandle*) which is usually already filled out by a Service Discovery procedure. If not, they need to be written manually.

Also, the service structure's *aCharacteristics* field must be linked to an allocated characteristic array.

The following example discovers all Characteristics contained in the Heart Rate Service discovered in Section Discover primary services by UUID.

```
gattService_t* pService = &heartRateService
#define mcMaxCharacteristics_c 10
static gattCharacteristic_t hrsCharacteristics[mcMaxCharacteristics_c];
pService->aCharacteristics = hrsCharacteristics;
bleResult_t result = GattClient_DiscoverAllCharacteristicsOfService
(
  deviceId,
  pService,
  mcMaxCharacteristics_c
);
```

The Client Procedure Callback is triggered when the procedure completes.

```
void gattClientProcedureCallback
(
  deviceId_t                deviceId,
  gattProcedureType_t       procedureType,
  gattProcedureResult_t     procedureResult,
  bleResult_t               error
)
{
```

(continues on next page)

(continued from previous page)

```
    switch (procedureType)
    {
      /* ... */
      case gGattProcDiscoverAllCharacteristics_c:
          if (gGattProcSuccess_c == procedureResult)
          {
            /* Read number of discovered Characteristics */
             PRINT(pService-> cNumCharacteristics );
            /* Read discovered Characteristics data */
             for ( uint8_t j = 0; j < pService-> cNumCharacteristics ; j++)
               {
            /* Characteristic UUID is found inside the value field
              to avoid duplication */
                  PRINT(pService-> aCharacteristics [j]. value . uuidType );
                  PRINT(pService-> aCharacteristics [j]. value . uuid );
            /* Characteristic Properties indicating the supported operations:
                   * - Read
                   * - Write
                   * - Write Without Response
                   * - Notify
                   * - Indicate
           */
                  PRINT(pService-> aCharacteristics [j]. properties );
           /* Characteristic Value Handle is used to identify the
             Characteristic in future operations */
                  PRINT(pService-> aCharacteristics [j]. value . handle );
               }
            }
            else
            {
               /* Handle error */
               PRINT( error );
            }
            break;
        /* ... */
    }
}
```

Parent topic: Service and characteristic discovery

Discover characteristics by UUID

This procedure is useful when the Client intends to discover a specific Characteristic in a specific Service. The API allows for multiple Characteristics of the same type to be discovered, but most often it is used when a single Characteristic of the given type is expected to be found.

Continuing the example from Discover primary services by UUID, assume the Client wants to discover the Heart Rate Control Point Characteristic inside the Heart Rate Service, as shown in the following code.

```
gattService_t * pService = &heartRateService;
static gattCharacteristic_t hrcpCharacteristic;
static uint8_t mcHrcpChar;
bleUuid_t hrcpUuid;
hrcpUuid.uuid16 = gBleSig_HrControlPoint_d;
bleResult_t result = GattClient_DiscoverCharacteristicOfServiceByUuid
(
    deviceId,
    gBleUuidType16_c,
    &hrcpUuid,
    pService,
```

(continues on next page)

(continued from previous page)

```
    &hrcpCharacteristic,
    1,
    &mcHrcpChar
);
```

This API can be used as in the previous examples, following a Service Discovery procedure. However, the user may want to perform a Characteristic search with UUID over the entire database, skipping the Service Discovery entirely. To do so, a dummy service structure must be defined and its range must be set to maximum, as shown in the following example:

```
gatt Service_t dummyService;
dummyService. startHandle = 0x0001;
dummyService. endHandle = 0xFFFF;
static gattCharacteristic_t hrcpCharacteristic;
static uint8_t mcHrcpChar;
bleResult_t result = GattClient_DiscoverCharacteristicOfServiceByUuid
(
    deviceId,
    gBleUuidType16_c,
    gBleSig_HrControlPoint_d,
    &dummyService,
    &hrcpCharacteristic,
    1,
    &mcHrcpChar
);
```

.

```
void gattClientProcedureCallback
(
    deviceId_t              deviceId,
    gattProcedureType_t     procedureType,
    gattProcedureResult_t   procedureResult,
    bleResult_t             error
)
{
    switch (procedureType)
    {
        /* ... */
        case gGattProcDiscoverCharacteristicByUuid_c:
            if (gGattProcSuccess_c == procedureResult)
            {
                if (1 == mcHrcpChar)
                {
                    /* HRCP found, read discovered data */
                    PRINT(hrcpCharacteristic. properties );
                    PRINT(hrcpCharacteristic. value . handle );
                }
                else
                {
                    /* HRCP not found! */
                }
            }
            else
            {
                /* Handle error */
                PRINT(error);
            }
            break;
        /* ... */
    }
```

(continues on next page)

Parent topic: Service and characteristic discovery

Discover characteristic descriptors

To discover all descriptors of a Characteristic, the following API is provided:

```
bleResult_t GattClient_DiscoverAllCharacteristicDescriptors
(
    deviceId_t                deviceId,
    gattCharacteristic_t *    pIoCharacteristic,
    uint16_t                  endingHandle,
    uint8_t                   maxDescriptorCount
);
```

The *pIoCharacteristic* pointer must point to a Characteristic structure with the *value.handle* field set (either by a discovery operation or by the application) and the *aDescriptors* field pointed to an allocated array of Descriptor structures.

The *endingHandle* should be set to the handle of the next Characteristic or Service declaration in the database to indicate when the search for descriptors must stop. The GATT Client module uses ATT Find Information Requests to discover the descriptors, and it does so until it discovers a Characteristic or Service declaration or until *endingHandle* is reached. Thus, by providing a correct ending handle, the search for descriptors is optimized and the number of packets sent over the air is reduced.

If, however, the application does not know where the next declaration lies and cannot provide this optimization hint, the *endingHandle* should be set to *0xFFFF*.

Continuing the example from Discover characteristics by UUID, the following code assumes that the Heart Rate Control Point Characteristic has no more than 5 descriptors and performs Descriptor Discovery.

```
#define mcMaxDescriptors_c 5
static gattAttribute_t aDescriptors[mcMaxDescriptors_c];
hrcpCharacteristic. aDescriptors = aDescriptors;
bleResult_t result = GattClient_DiscoverAllCharacteristicDescriptors
(
    deviceId,
    &hrcpCharacteristic,
    0xFFFF, /* We do not know where the next Characterstic Service begins */
    mcMaxDescriptors_c
);
if (gBleSuccess_c != result)
{
    /* Handle error */
}
```

The Client Procedure Callback is triggered at the end of the procedure.

```
void gattClientProcedureCallback
(
    deviceId_t              deviceId,
    gattProcedureType_t     procedureType,
    gattProcedureResult_t   procedureResult,
    bleResult_t             error
)
{
    switch (procedureType)
    {
```

(continues on next page)

(continued from previous page)

```
        /* ... */
        case gGattProcDiscoverAllCharacteristicDescriptors_c:
            if (gGattProcSuccess_c == procedureResult)
            {
                /* Read number of discovered descriptors */
                PRINT(hrcpCharacteristic. cNumDescriptors );
                /* Read descriptor data */
                for ( uint8_t j = 0; j < hrcpCharacteristic. cNumDescriptors ; j++)
                {
                    PRINT(hrcpCharacteristic. aDescriptors [j]. handle );
                    PRINT(hrcpCharacteristic. aDescriptors [j]. uuidType );
                    PRINT(hrcpCharacteristic. aDescriptors [j]. uuid );
                }
            }
            else
            {
                /* Handle error */
                PRINT(error);
            }
            break;
        /* ... */
    }
}
```

Parent topic: Service and characteristic discovery

Parent topic: Client APIs

Reading and writing characteristics

All the APIs described in the following sections have an enhanced counterpart of the form *GattClient_Enhanced[procedure]*. A *bearer id* parameter was added to specify on which bearer the transaction should take place. A value of *0* for the bearer id identifies the Unenhanced ATT bearer. Values higher than *0* are used to identify the Enhanced ATT bearer used for the ATT procedure.

Characteristic value read procedure

The main API for reading a Characteristic Value is shown here:

```
bleResult_t GattClient_ReadCharacteristicValue
(
    deviceId_t                deviceId,
    gattCharacteristic_t *    pIoCharacteristic,
    uint16_t                  maxReadBytes
);
```

This procedure assumes that the application knows the Characteristic Value Handle, usually from a previous Characteristic Discovery procedure. Therefore, the *value.handle* field of the structure pointed by *pIoCharacteristic* must be completed.

Also, the application must allocate a large enough array of bytes where the received value (from the ATT packet exchange) is written. The *maxReadBytes* parameter is set to the size of this allocated array.

The GATT Client module takes care of long characteristics, whose values have a greater length than can fit in a single ATT packet, by issuing repeated ATT Read Blob Requests when needed.

The following examples assume that the application knows the Characteristic Value Handle and that the value length is variable, but limited to 50 bytes.

```
gattCharacteristic_t myCharacteristic;
myCharacteristic. value . handle = 0x10AB;
#define mcMaxValueLength_c 50
static uint8_t aValue[mcMaxValueLength_c];
myCharacteristic. value . paValue = aValue;
bleResult_t result = GattClient_ReadCharacteristicValue
(
    deviceId,
    &myCharacteristic,
    mcMaxValueLength_c
);
if (gBleSuccess_c != result)
{
    /* Handle error */
}
```

Regardless of the value length, the Client Procedure Callback is triggered when the reading is complete. The received value length is also filled in the *value* structure.

```
void gattClientProcedureCallback
(
    deviceId_t              deviceId,
    gattProcedureType_t     procedureType,
    gattProcedureResult_t   procedureResult,
    bleResult_t             error
)
{
    switch (procedureType)
    {
        /* ... */
        case gGattProcReadCharacteristicValue_c:
            if (*gGattProcSuccess_c == procedureResult)
            {
                /* Read value length */
                PRINT(myCharacteristic. value . valueLength );
                /* Read data */
                for ( uint16_t j = 0; j < myCharacteristic. value . valueLength ; j++)
                {
                    PRINT(myCharacteristic. value . paValue [j]);
                }
            }
            else
            {
                /* Handle error */
                PRINT(error);
            }
            break;
        /* ... */
    }
}
```

Parent topic: Reading and writing characteristics

Characteristic read by UUID procedure

This API for this procedure is shown here:

```
bleResult_t GattClient_ReadUsingCharacteristicUuid
(
    deviceId_t              deviceId,
    bleUuidType_t           uuidType,
    const bleUuid_t*        pUuid,
```

(continues on next page)

(continued from previous page)

```
    const gattHandleRange_t* pHandleRange,
    uint8_t*                 aOutBuffer,
    uint16_t                 maxReadBytes,
    uint16_t*                pOutActualReadBytes
);
```

This provides support for an important optimization, which involves reading a Characteristic Value without performing any Service or Characteristic Discovery.

For example, the following is the process to write an application that connects to any Server and wants to read the device name.

The device name is contained in the Device Name Characteristic from the GAP Service. Therefore, the necessary steps involve discovering all primary services, identifying the GAP Service by its UUID, discovering all Characteristics of the GAP Service and identifying the Device Name Characteristic (alternatively, discovering Characteristic by UUID inside GAP Service), and, finally, reading the device name by using the Characteristic Read Procedure.

Instead, the Characteristic Read by UUID Procedure allows reading a Characteristic with a specified UUID, assuming one exists on the Server, without knowing the Characteristic Value Handle.

The described example is implemented as follows:

```
#define mcMaxValueLength_c 10 /* Sample value length , adjust as needed */
/* First byte is for handle-value pair length. Next 2 bytes are the handle */
static uint8_t aValue[1 + 2 + mcMaxValueLength_c];
static uint16_t deviceNameLength;
bleUuid_t uuid = {
        .uuid16 = gBleSig_GapDeviceName_d
};
bleResult_t result = GattClient_ReadUsingCharacteristicUuid
(
    deviceId,
    gBleUuidType16_c,
    &uuid,
    &pHandleRange,
    aValue,
    1 + 2 + mcMaxValueLength_c,
    &deviceNameLength
);
if (gBleSuccess_c != result)
{
    /* Handle error */
}
```

The Client Procedure Callback is triggered when the reading is complete. Because only one air packet is exchanged during this procedure, it can only be used as a quick reading of Characteristic Values with length no greater than *ATT_MTU – 1*.

```
void gattClientProcedureCallback
(
    deviceId_t                deviceId,
    gattProcedureType_t       procedureType,
    gattProcedureResult_t     procedureResult,
    bleResult_t               error
)
{
    switch (procedureType)
    {
        /* ... */
         case gGattProcReadUsingCharacteristicUuid_c:
             if (gGattProcSuccess_c == procedureResult)
```

(continues on next page)

(continued from previous page)

```
        {
          /* Read handle-value pair length */
          PRINT(aValue[0]);
          deviceNameLength -= 1;
         /* Read characteristic value handle */
          PRINT(aValue[1] | (aValue[2] << 8));
          deviceNameLength -= 2;
          /* Read value length */
          PRINT(deviceNameLength);
          /* Read data */
          for ( uint8_t j = 0; j < deviceNameLength; j++)
          {
            PRINT(aValue[3 + j]);
          }
        }
         else
        {
          /* Handle error */
          PRINT(error);
        }
        break;
      /* ... */
  }
}
```

Parent topic: Reading and writing characteristics

Characteristic read multiple procedure

The API for this procedure is shown here:

```
bleResult_t GattClient_ReadMultipleCharacteristicValues
(
  deviceId_t                deviceId,
  uint8_t                   cNumCharacteristics,
  gattCharacteristic_t *    aIoCharacteristics
);
```

This procedure also allows an optimization for a specific situation, which occurs when multiple Characteristics, whose values are of known, fixed-length, can be all read in one single ATT transaction (usually one single over-the-air packet).

The application must know the value handle and value length of each Characteristic. It must also write the *value.handle*and *value.maxValueLength* with the aforementioned values, respectively, and then link the *value.paValue* field with an allocated array of size *maxValueLength*.

The following example involves reading three characteristics in a single packet.

```
#define mcNumCharacteristics_c 3
#define mcChar1Length_c 4
#define mcChar2Length_c 5
#define mcChar3Length_c 6
static uint8_t aValue1[mcChar1Length_c];
static uint8_t aValue2[mcChar2Length_c];
static uint8_t aValue3[mcChar3Length_c];
static gattCharacteristic_t myChars[mcNumCharacteristics_c];
myChars[0]. value . handle = 0x0015;
myChars[1]. value . handle = 0x0025;
myChars[2]. value . handle = 0x0035;
myChars[0]. value . maxValueLength = mcChar1Length_c;
myChars[1]. value . maxValueLength = mcChar2Length_c;
```

(continues on next page)

(continued from previous page)

```
myChars[2]. value . maxValueLength = mcChar3Length_c;
myChars[0]. value . paValue = aValue1;
myChars[1]. value . paValue = aValue2;
myChars[2]. value . paValue = aValue3;
bleResult_t result = GattClient_ReadMultipleCharacteristicValues
(
    deviceId,
    mcNumCharacteristics_c,
    myChars
);
if (gBleSuccess_c != result)
{
    /* Handle error */
}
```

When the Client Procedure Callback is triggered, if no error occurs, each Characteristic's value length should be equal to the requested lengths.

```
void gattClientProcedureCallback
(
    deviceId_t              deviceId,
    gattProcedureType_t p  rocedureType,
    gattProcedureResult_t  procedureResult,
    bleResult_t             error
)
{
    switch (procedureType)
    {
        /* ... */
      case gGattProcReadMultipleCharacteristicValues_c:
            if (gGattProcSuccess_c == procedureResult)
            {
                for ( uint8_t i = 0; i < mcNumCharacteristics_c; i++)
                {
                    /* Read value length */
                    PRINT(myChars[i]. value . valueLength );
                    /* Read data */
                    for ( uint8_t j = 0; j < myChars[i]. value . valueLength ; j++)
                    {
                        PRINT(myChars[i]. value . paValue [j]);
                    }
                }
            }
            else
            {
                /* Handle error */
                PRINT(error);
            }
            break;
        /* ... */
    }
}
```

If the server does not know the length of the characteristic values, then the Read Multiple Variable Characteristic Values procedure can be used. This sub-procedure is used to read multiple characteristic values of variable length from a server when the client knows the characteristic value handles. The response returns the characteristic values and their corresponding lengths in the Length Value Tuple List parameter.

```
bleResult_t GattClient_ReadMultipleVariableCharacteristicValues
(
```

(continues on next page)

(continued from previous page)

```
  deviceId_t              deviceId,
  uint8_t                 cNumCharacteristics,
  gattCharacteristic_t*   pIoCharacteristics
);
```

The following example involves reading three characteristics of variable length in a single packet.

```
#define mcNumCharacteristics_c 3
#define mcCharLengthMax_c 10
static uint8_t aValue1[mcCharLengthMax _c];
static uint8_t aValue2[mcCharLengthMax _c];
static uint8_t aValue3[mcCharLengthMax _c];
static gattCharacteristic_t myChars[mcNumCharacteristics_c];
myChars[0].value .handle = 0x0015;
myChars[1].value .handle = 0x0025;
myChars[2].value .handle = 0x0035;
myChars[0].value .paValue = aValue1;
myChars[1].value .paValue = aValue2;
myChars[2].value .paValue = aValue3;
bleResult_t result = GattClient_ReadMultipleVariableCharacteristicValues
(
    deviceId,
    mcNumCharacteristics_c,
    pIoCharacteristics
);
if (gBleSuccess_c != result)
{
    /* Handle error */
}
```

The result of this procedure is sent to the application via the GATT procedure callback. The response includes the characteristic value together with a handle, length pair corresponding to each characteristic.

```
static void BleApp_GattClientCallback
(
    deviceId_t              serverDeviceId,
    gattProcedureType_t     procedureType,
    gattProcedureResult_t   procedureResult,
    bleResult_t             error
)
{
    switch (procedureResult)
    {
        /* ... */
        case gGattProcReadMultipleVarLengthCharValues_c:
            if (gGattProcSuccess_c == procedureResult)
            {
                for (uint8_t i = 0; i < mcNumCharacteristics_c; i++)
                {
                    /* Print characteristic handle and length */
                    PRINT(myChars[i].value.handle);
                    PRINT(myChars[i].value.valueLength);
                    for (uint8_t j = 0; j < myChars[i].value.maxValueLength; j++)
                    {
                        /* Print characteristic value */
                        PRINT(myChars[i].value.paValue[j]);
                    }
                }
            }
```

(continues on next page)

(continued from previous page)

```
        else
        {
            /* Handle error */
        }
        break;
}
```

Parent topic: Reading and writing characteristics

Characteristic write procedure

There is a general API that may be used for writing Characteristic Values:

```
bleResult_t GattClient_WriteCharacteristicValue
(
    deviceId_t                      deviceId,
    const gattCharacteristic_t *        pCharacteristic,
    uint16_t                        valueLength,
    const uint8_t *                   aValue,
    bool_t                          withoutResponse,
    bool_t                          signedWrite,
    bool_t                          doReliableLongCharWrites,
    const uint8_t *                   aCsrk
);
```

It has many parameters to support different combinations of Characteristic Write Procedures.

The structure pointed to by the *pCharacteristic* is only used for the *value.handle*field which indicates the Characteristic Value Handle. The value to be written is contained in the *aValue* array of size *valueLength*.

The *withoutResponse* parameter can be set to *TRUE* if the application wishes to perform a Write Without Response Procedure, which translates into an ATT Write Command. Both *signedWrite* and *aCsrk* are deprecated and ignored.

Finally, *doReliableLongCharWrites* should be sent to *TRUE* if the application is writing a long Characteristic Value (one that requires multiple air packets due to *ATT_MTU* limitations) and wants the Server to confirm each part of the attribute that is sent over the air.

To simplify the application code, the following macros are defined:

```
#define GattClient_SimpleCharacteristicWrite(deviceId, pChar, valueLength, aValue) \
    GattClient_WriteCharacteristicValue\
        (deviceId, pChar, valueLength, aValue, FALSE, FALSE, FALSE, NULL)
```

This is the simplest usage for writing a Characteristic. It sends an ATT Write Request if the value length does not exceed the maximum space for an over-the-air packet (*ATT_MTU – 3*). Otherwise, it sends ATT Prepare Write Requests with parts of the attribute, without checking the ATT Prepare Write Response data for consistency, and in the end an ATT Execute Write Request.

```
#define GattClient_CharacteristicWriteWithoutResponse(deviceId, pChar, valueLength, aValue) \
    GattClient_WriteCharacteristicValue\
        (deviceId, pChar, valueLength, aValue, TRUE, FALSE, FALSE, NULL)
```

This usage sends an ATT Write Command. Long Characteristic values are not allowed here and trigger a *gBleInvalidParameter_c* error.

This is a short example to write a 3-byte long Characteristic Value.

```
gattCharacteristic_t myChar;
myChar. value . handle = 0x00A0; /* Or maybe it was previously discovered? */
#define mcValueLength_c 3
```

(continues on next page)

(continued from previous page)

```
uint8_t aValue[mcValueLength_c] = { 0x01, 0x02, 0x03 };
bleResult_t result = GattClient_SimpleCharacteristicWrite
(
    deviceId,
    &myChar,
    mcValueLength_c,
    aValue
);
if (gBleSuccess_c != result)
{
    /* Handle error */
}
```

The Client Procedure Callback is triggered when writing is complete.

```
void gattClientProcedureCallback
(
    deviceId_t              deviceId,
    gattProcedureType_t     procedureType,
    gattProcedureResult_t   procedureResult,
    bleResult_t             error
)
{
    switch (procedureType)
    {
        /* ... */
        case gGattProcWriteCharacteristicValue_c:
            if (gGattProcSuccess_c == procedureResult)
            {
                /* Continue */
            }
            else
            {
                /* Handle error */
                PRINT(error);
            }
            break;
        /* ... */
    }
}
```

Parent topic: Reading and writing characteristics

Parent topic: Client APIs

Reading and writing characteristic descriptors

Two APIs are provided for these procedures which are very similar to Characteristic Read and Write.

The only difference is that the handle of the attribute to be read/written is provided through a pointer to an *gattAttribute_t* structure (same type as the *gattCharacteristic_t.value* field).

All of the following APIs have an enhanced counterpart of the form *GattClient_Enhanced[procedure]*. A *bearerId*parameter was added to specify on which bearer the transaction should take place. A value of *0* for the bearer Id identifies the Unenhanced ATT bearer. Values higher than *0* are used to identify the Enhanced ATT bearer used for the ATT procedure.

```
bleResult_t GattClient_ReadCharacteristicDescriptor
(
```

(continues on next page)

(continued from previous page)

```
    deviceId_t              deviceId,
    gattAttribute_t *       pIoDescriptor,
    uint16_t                maxReadBytes
);
```

The *pIoDescriptor->handle* is required (it may have been discovered previously by *GattClient_DiscoverAllCharacteristicDescriptors*). The GATT module fills the value that was read in the fields *pIoDescriptor->aValue* (must be linked to an allocated array) and *pIoDescriptor->valueLength* (size of the array).

Writing a descriptor is also performed similarly with this function:

```
bleResult_t GattClient_WriteCharacteristicDescriptor
(
    deviceId_t              deviceId,
    gattAttribute_t *       pDescriptor,
    uint16_t                valueLength,
    uint8_t *               aValue
);
```

Only the *pDescriptor->handle* must be filled before calling the function.

One of the most frequently written descriptors is the Client Characteristic Configuration Descriptor (CCCD). It has a well-defined UUID (*gBleSig_CCCD_d*) and a 2-byte long value that can be written to enable/disable notifications and/or indications.

In the following example, a Characteristic's descriptors are discovered and its CCCD written to activate notifications.

```
static gattCharacteristic_t myChar;
myChar.value.handle = 0x00A0; /* Or maybe it was previously discovered? */
#define mcMaxDescriptors_c 5
static gattAttribute_t aDescriptors[mcMaxDescriptors_c];
myChar.aDescriptors = aDescriptors;
/* ... */
{
    bleResult_t result = GattClient_DiscoverAllCharacteristicDescriptors
    (
        deviceId,
        &myChar,
        0xFFFF,
        mcMaxDescriptors_c
    );
    if (gBleSuccess_c != result)
    {
        /* Handle error */
    }
}
/* ... */
void gattClientProcedureCallback
(
    deviceId_t                  deviceId,
    gattProcedureType_t         procedureType,
    gattProcedureResult_t       procedureResult,
    bleResult_t                 error
)
{
    switch (procedureType)
    {
      /* ... */
      case gGattProcDiscoverAllCharacteristicDescriptors_c:
        if (gGattProcSuccess_c == procedureResult)
```

(continues on next page)

(continued from previous page)

```
        {
         /* Find CCCD */
          for ( uint8_t j = 0; j < myChar.cNumDescriptors; j++)
             {
              if ((myChar.aDescriptors[j].uuidType == gBleUuidType16_c) &&
                  (gBleSig_CCCD_d == myChar.aDescriptors[j].uuid.uuid16))
               {
                  uint8_t cccdValue[2];
                  packTwoByteValue(gCccdNotification_c, cccdValue);
                  bleResult_t result = GattClient_WriteCharacteristicDescriptor
                   (
                     deviceId,
                     &myChar. aDescriptors [j],
                     2,
                     (uint8_t*)&cccdValue
                   );
                  if (gBleSuccess_c != result)
                     {
                      /* Handle error */
                     }
                     break;
                   }
             }
          }
          else
          {
              /* Handle error */
              PRINT(error);
          }
          break;
       case gGattProcWriteCharacteristicDescriptor_c:
          if (gGattProcSuccess_c == procedureResult)
          {
              /* Notification successfully activated */
          }
          else
          {
              /* Handle error */
              PRINT(error);
          }
       /* ... */
    }
}
```

Parent topic: Client APIs

Resetting procedures

To cancel an ongoing Client Procedure, the following API can be called:

```
bleResult_t GattClient_ResetProcedure (void);
```

It resets the internal state of the GATT Client and new procedure may be started at any time.

Parent topic: Client APIs

Parent topic:*Generic Attribute Profile (GATT) Layer*

Server APIs

Once the GATT Database has been created and the required security settings have been registered with *Gap_RegisterDeviceSecurityRequirements*, all ATT Requests and Commands and at-

tribute access security checks are handled internally by the GATT Server module.

Besides this automatic functionality, the application may use GATT Server APIs to send Notifications and Indication and, optionally, to intercept Clients' attempts to write certain attributes.

Server callback

The first GATT Server call is the installation of the Server Callback, which has the following prototype:

```
typedef void (* gattServerCallback_t )
(
    deviceId_t              deviceId,    /*!< Device ID identifying the active connection. */
    gattServerEvent_t *     pServerEvent /*!< Server event. */
);
```

For EATT, the following signature should be used:

```
typedef void (*gattServerEnhancedCallback_t) ( deviceId_t deviceId, bearerId_t bearerId, gattServerEvent_
↪t* pServerEvent );
```

The callback can be installed with:

```
bleResult_t GattServer_RegisterCallback
(
    gattServerCallback_t callback
);
```

The EATT server callback should be installed using the following API:

```
bleResult_t GattServer_RegisterEnhancedCallback
(
     gattServerEnhancedCallback_t callback
);
```

The first member of the *gattServerEvent_t* structure is the *eventType*, an enumeration type with the following possible values:

- *gEvtMtuChanged_c:* Signals that the Client-initiated MTU Exchange Procedure has completed successfully and the *ATT_MTU* has been increased. The event data contains the new value of the *ATT_MTU*. Is it possible that the application flow depends on the value of the *ATT_MTU*, for example, there may be specific optimizations for different *ATT_MTU* ranges. This event is not triggered if the *ATT_MTU* was not changed during the procedure.
- *gEvtHandleValueConfirmation_c:* A Confirmation was received from the Client after an Indication was sent by the Server.
- *gEvtAttributeWritten_c, gEvtAttributeWrittenWithoutResponse_c:* See Attribute write notifications.
- *gEvtCharacteristicCccdWritten_c:* The Client has written a CCCD. The application should save the CCCD value for bonded devices with *Gap_SaveCccd*.
- *gEvtError_c:* An error occurred during a Server-initiated procedure.
- *gEvtLongCharacteristicWritten_c*: A long characteristic was written.
- *gEvtInvalidPduReceived_c*: An invalid PDU was received from Client. Application decides if disconnection is required.
- *gEvtAttributeRead_c*: An attribute registered with GattServer_RegisterHandlesForReadNotifications is being read.

Parent topic: Server APIs

Sending notifications and indications

The APIs provided for these Server-initiated operations are very similar.

All of the following APIs have an enhanced counterpart of the form *GattServer_Enhanced[procedure]*. A *bearerId* parameter was added to specify on which bearer the transaction should take place. A value of *0* for the bearerId identifies the Unenhanced ATT bearer. Values higher than*0* are used to identify the Enhanced ATT bearer used for the ATT procedure.

```
bleResult_t GattServer_SendNotification
(
    deviceId_t      deviceId,
    uint16_t        handle
);
bleResult_t GattServer_SendIndication
(
    deviceId_t      deviceId,
    uint16_t        handle
);
```

Only the attribute handle needs to be provided to these functions. The attribute value is automatically retrieved from the GATT Database.

Note: It is the application developer's responsibility to check if the Client designated by the *deviceId* has previously activated Notifications/Indications by writing the corresponding CCCD value. To do that, the following GAP APIs should be used:

```
bleResult_t Gap_CheckNotificationStatus
(
    deviceId_t      deviceId,
    uint16_t        handle,
    bool_t *        pOutIsActive
);
bleResult_t Gap_CheckIndicationStatus
(
    deviceId_t      deviceId,
    uint16_t        handle,
    bool_t *        pOutIsActive
    );
```

Note: It is necessary to use these two functions with the *Gap_SaveCccd* only for bonded devices, because the data is saved in NVM and reloaded at reconnection. For devices that do not bond, the application may also use its own bookkeeping mechanism.

There is an important difference between sending **Notifications and Indications**:

- The latter can only be sent one at a time. In addition, the application must wait for the Client Confirmation (signaled by the *gEvtHandleValueConfirmation_c* Server event, or by a *gEvtError_c* event with *gGattClientConfirmationTimeout_c* error code) before sending a new Indication. Otherwise, a *gEvtError_c* event with *gGattIndicationAlreadyInProgress_c* error code is triggered.
- The Notifications can be sent consecutively.

Parent topic: Server APIs

Attribute write notifications

When the GATT Client reads and writes values from/into the Server's GATT Database, it uses ATT Requests.

The GATT Server module implementation manages these requests and, according to the database security settings and the Client's security status (authenticated, authorized, and so on), automatically sends the ATT Responses without notifying the application.

There are however some situations where the application needs to be informed of ATT packet exchanges. For example, a lot of standard profiles define, for certain Services, some, so-called, Control-Point Characteristics. These are Characteristics whose values are only of immediate significance to the application. Writing these Characteristics usually triggers specific actions.

For example, consider a fictitious Smart Lamp. It has Bluetooth Low Energy connectivity in the Peripheral role and it contains a small GATT Database with a Lamp Service (among other Services). The Lamp Service contains two Characteristics: the Lamp State Characteristic (LSC) and the Lamp Action Characteristic (LAC).

LSC is a "normal" Characteristic with Read and Write properties. Its value is either 0, lamp off, or 1, lamp on). Writing the value sets the lamp in the desired state. Reading it provides its current state, which is only useful when passing the information remotely.

The LAC has only one property, which is Write Without Response. The user can use the Write Without Response procedure to write only the value 0x01 (all other values are invalid). Whenever the user writes 0x01 in LAC, the lamp switches its state.

The LAC is a good example of a Control-Point Characteristic for these reasons:

- Writing a certain value (in this case 0x01) triggers an action on the lamp.
- The value the user writes has immediate significance only ("0x01 switches the lamp") and is never used again in the future. For this reason, it does not need to be stored in the database.

Obviously, whenever a Control-Point Characteristic is written, the application must be notified to trigger some application-specific action.

The GATT Server allows the application to register a set of attribute handles as "write-notifiable", in other words, the application wants to receive an event each time any of these attributes is written by the peer Client.

All Control-Point Characteristics in the GATT Database must have their Value handle registered. In fact, the application may register any other handle for write notifications for its own purposes with the following API:

```
bleResult_t GattServer_RegisterHandlesForWriteNotifications
(
    uint8_t         handleCount,
    const uint16_t *      aAttributeHandles
);
```

The *handleCount* is the size of the *aAttributeHandles* array and it cannot exceed *gcGattMaxHandleCountForWriteNotifications_c*.

After an attribute handle has been registered with this function, whenever the Client attempts to write its value, the GATT Server Callback is triggered with one of the following event types:

- *gEvtAttributeWritten_c* is triggered when the attribute is written with a Write procedure (ATT Write Request). In this instance, the application has to decide whether the written value is valid and whether it must be written in the database, and, if so, the application must write the value with the *GattDb_WriteAttribute*, see *GATT database application interface*. At this point, the GATT Server module does not automatically send the ATT Write Response over the air. Instead, it waits for the application to call this function:

```
bleResult_t GattServer_SendAttributeWrittenStatus
(
    deviceId_t      deviceId,
    uint16_t        attributeHandle,
    uint8_t         status
);
```

This API also has an enhanced counterpart, which adds the *bearerId* parameter.

The value of the *status* parameter is interpreted as an ATT Error Code. It must be equal to the *gAttErrCodeNoError_c* (0x00) if the value is valid and it is successfully processed by the appli-

cation. Otherwise, it must be equal to a profile-specific error code (in interval 0xE0-0xFF) or an application-specific error code (in interval 0x80-0x9F).

- *gEvtAttributeWrittenWithoutResponse_c* is triggered when the attribute is written with a Write Without Response procedure (ATT Write Command). Because this procedure expects no response, the application may process it and, if necessary, write it in the database. Regardless of whether the value is valid or not, no response is needed from the application.
- *gEvtLongCharacteristicWritten_c* is triggered when the Client has completed writing a Long Characteristic value; the event data includes the handle of the Characteristic Value attribute and a pointer to its value in the database.

Attributes can also be registered for read notifications using the followng API:

```
bleResult_t GattServer_RegisterHandlesForReadNotifications
(
 uint8_t handleCount,
 const uint16_t* aAttributeHandles
);
```

To unregister one or more handles from the list for either write or read, the following APIs can be used:

```
bleResult_t GattServer_UnregisterHandlesForWriteNotifications
(
 uint8_t handleCount,
 const uint16_t* aAttributeHandles
);

bleResult_t GattServer_UnregisterHandlesForReadNotifications
(
 uint8_t handleCount,
 const uint16_t* aAttributeHandles
);
```

Parent topic: Server APIs

Parent topic:*Generic Attribute Profile (GATT) Layer*

GATT database application interface

For over-the-air packet exchanges between a Client and a Server, the GATT Server module automatically retrieves data from the GATT database and responds to all ATT Requests from the peer Client, provided it passes the security checks. This ensures that the Server application does not have to perform any kind of searches over the database.

However, the application must have access to the database to write meaningful data into its characteristics. For example, a temperature sensor must periodically write the temperature, which is measured by an external thermometer, into the Temperature Characteristic.

For these kinds of situations, a few APIs are provided in the *gatt_db_app_interface.h* file.

Note: All functions provided by this interface are executed synchronously. The result of the operation is saved in the return value and it generates no event.

Writing and reading attributes

These are the two functions to perform basic attribute operations from the application:

```
bleResult_t GattDb_WriteAttribute
(
```

(continues on next page)

(continued from previous page)

```
    uint16_t            handle,
    uint16_t            valueLength,
    const uint8_t *     aValue
);
```

The value length must be valid, as defined when the database is created. Otherwise, a *gGattInvalidValueLength_c* error is returned.

Also, if the database is created statically, as explained in *Creating GATT database*, the *handle* may be referenced through the enumeration member with a friendly name defined in the *gatt_db.h*.

```
bleResult_t GattDb_ReadAttribute
(
    uint16_t      handle,
    uint16_t      maxBytes,
    uint8_t *     aOutValue,
    uint16_t *    pOutValueLength
);
```

The *aOutValue* array must be allocated with the size equal to *maxBytes*.

Parent topic:*GATT database application interface*

Finding attribute handles

Although the application should be fully aware of the contents of the GATT Database, in certain situations it might be useful to perform some dynamic searches of certain attribute handles.

To find the handle value for a Service for which only the UUID is know the following API can be used:

```
bleResult_t GattDb_FindServiceHandle
(
 uint16_t startHandle,
 bleUuidType_t serviceUuidType,
 const bleUuid_t* pServiceUuid,
 uint16_t* pOutServiceHandle
);
```

To find a specific Characteristic Value Handle in a Service whose declaration handle is known, the following API is provided:

```
bleResult_t GattDb_FindCharValueHandleInService
(
    uint16_t                serviceHandle,
    bleUuidType_t           characteristicUuidType,
    const bleUuid_t *       pCharacteristicUuid,
    uint16_t *              pOutCharValueHandle
);
```

If the return value is *gBleSuccess_c*, the handle is written at *pOutCharValueHandle*. If the *serviceHandle* is invalid or not a valid Service declaration, the *gBleGattDbInvalidHandle_c* is returned. Otherwise, the search is performed starting with the *serviceHandle+1*. If no Characteristic of the given UUID is found, the function returns the *gBleGattDbCharacteristicNotFound_c* value.

To find a Characteristic Descriptor of a given type in a Characteristic, when the Characteristic Value Handle is known, the following API is provided:

```
bleResult_t GattDb_FindDescriptorHandleForCharValueHandle
(
    uint16_t            charValueHandle,
    bleUuidType_t       descriptorUuidType,
```

(continues on next page)

(continued from previous page)

```
    const bleUuid_t *   pDescriptorUuid,
    uint16_t *          pOutDescriptorHandle
);
```

Similarly, the function returns *gBleGattDbInvalidHandle_c* is the handle is invalid. Otherwise, it starts searching from the *charValueHandle+1*. Then, *gBleGattDbDescriptorNotFound_c* is returned if no Descriptor of the specified type is found. Otherwise, its attribute handle is written at the *pOutDescriptorHandle* and the function returns *gBleSuccess_c*.

One of the most commonly used Characteristic Descriptors is the Client Configuration Characteristic Descriptor (CCCD), which has the UUID equal to *gBleSig_CCCD_d*. For this specific type, a special API is used as a shortcut:

```
bleResult_t GattDb_FindCccdHandleForCharValueHandle
(
    uint16_t      charValueHandle,
    uint16_t *    pOutCccdHandle
);
```

Parent topic:*GATT database application interface*

Creating GATT database

The GATT Database contains several *GATT Services* where each Service must contain at least one *GATT Characteristic*.

The Attribute Database contains a collection of *attributes*. Each attribute has four fields:

- The *attribute handle* – a 2-byte database index, which starts from 0x0001 and increases with each new attribute, not necessarily consecutive; maximum value is 0xFFFF.
- The *attribute type* or *UUID* – a 2-byte or 16-byte UUID.
- The *attribute permissions* – 1 byte containing access flags; this defines whether the attribute's value can be read or written and the security requirements for each operation type
- The *attribute value* – an array of maximum 512 bytes.

The ATT does not interpret the UUIDs and values contained in the database. It only deals with data transfer based on the attributes' handles.

The GATT gives meaning to the attributes based on their UUIDs and groups them into Characteristics and Services.

There are two possible ways of defining the GATT database:

- At compile-time (statically) or
- At runtime (dynamically)

Creating static GATT database

To define a GATT Database at compile-time, several macros are provided by the GATT_DB API. These macros expand in many different ways at compilation, generating the corresponding *Attribute Database* on which the Attribute Protocol (ATT) may operate.

This is the default way of defining the database.

The GATT Database definition is written in two files that are required to be added to the application project together with all macro expansion files:

- ***gatt_db.h*** - contains the actual declaration of Services and Characteristics.

- ***gat_uuid128.h*** – contains the declaration of Custom UUIDs (16-byte wide); these UUIDs are given a user-friendly name that is used in *gatt_db.h* file instead of the entire 16-byte sequence.

Declaring custom 128-bit UUIDs

All Custom 128-bit UUIDs are declared in the required file *gatt_uuid128.h*.

Each line in this file contains a single UUID declaration. The declaration uses the following macro:

- *UUID128 (name, byte1, byte2, ..., byte16)*

The*name* parameter is the user-friendly handle that references this UUID in the *gatt_db.h*file.

The 16 bytes are written in the *LSB-first* order each one using the 0xZZ format.

Note: On some occasions, it is desired to reuse an 128-bit UUID declared in *gatt_uuid128.h*. The 16 byte array is available through its friendly name and be accessed by including *gatt_db_handles.h* in the application. It is strongly advised to use it only in read-only operations. For example:

```
(gatt_uuid128.h)
UID128(uuid_service_wireless_uart, 0xE0, 0x1C, 0x4B, 0x5E, 0x1E, 0xEB, 0xA1, 0x5C, 0xEE, 0xF4, 0x5E,␣
↪0xBA, 0x00, 0x01, 0xFF, 0x01)
(app.c)
#include "gatt_db_handles.h"
.....
/* Start Service Discovery*/
BleServDisc_FindService(peerDeviceId, gBleUuidType128_c, (bleUuid_t*) &uuid_service_wireless_uart);
```

Parent topic: Creating static GATT database

Declaring a service

There are two types of Services:

- *Primary Services*
- *Secondary Services* - these are only to be included by other Primary or Secondary Services

The Service declaration attribute has one of these UUIDs, as defined by the Bluetooth SIG:

- 0x2800 a.k.a. *«Primary Service»* - for a Primary Service declaration
- 0x2801 a.k.a. *«Secondary Service»* - for a Secondary Service declaration

The Service declaration attribute permissions are read-only and no authentication required. The Service declaration attribute value contains the *Service UUID*. The *Service Range* starts from the Service declaration and ends at the next service declaration. All the Characteristics declared within the Service Range are considered to belong to that Service. For a more comprehensive list of SIG defied UUID values, check ble_sig_defines.h.

Service declaration macros

The following macros are to be used for declaring a Service:

- *PRIMARY_SERVICE (name, uuid16)*
  - Most often used.
  - The *name* parameter is common to all macros; it is a universal, user-friendly identifier for the generated attribute.
  - The *uuid16* is a 2-byte SIG-defined UUID, written in 0xZZZZ format.
- *PRIMARY_SERVICE_UUID32 (name, uuid32)*

  - This macro is used for a 4-byte, SIG-defined UUID, written in 0xZZZZZZZZ format.
- *PRIMARY_SERVICE_UUID128 (name, uuid128)*
  - The *uuid128* is the friendly name given to the custom UUID in the *gatt_uuid128.h* file.
- *SECONDARY _SERVICE (name, uuid16)*
- *SECONDARY_SERVICE_UUID32 (name, uuid32)*
- *SECONDARY _SERVICE_UUID128 (name, uuid128)*
  - All three are similar to Primary Service declarations.

Parent topic: Declaring a service

Include declaration macros

Secondary Services are meant to be included by other Services, usually by Primary Services. Primary Services may also be included by other Primary Services. The inclusion is done using the Include declaration macro:

- *INCLUDE (service_name)*
  - The *service_name* parameter is the friendly name used to declare the Secondary Service.
  - This macro is used only for Secondary Services with a SIG-defined, 2-byte, Service UUID.
- *INCLUDE_CUSTOM (service_name)*
  - This macro is used for Secondary Services that have either a 4-byte UUID or a 16-byte UUID.

The effect of the service inclusion is that the *including* Service is considered to contain all the Characteristics of the *included* Service.

Parent topic: Declaring a service

Parent topic: Creating static GATT database

Declaring a characteristic

A Characteristic must only be declared inside a Service. It belongs to the most recently declared Service, so the GATT Database must always begin with a Service declaration.

The Characteristic declaration attribute has the following UUID, as defined by the Bluetooth SIG:

- 0x2803 a.k.a. *«Characteristic»*

The Characteristic declaration attribute value contains:

- the *Characteristic UUID*
- the *Characteristic Value* 's declaration handle
- the *Characteristic Properties* – Read, Write, Notify, and so on. (1 byte of flags)

The *Characteristic Range*starts from the Characteristic declaration and ends before a new Characteristic or a Service declaration.

After the Characteristic declaration these follow:

- A *Characteristic Value* declaration (mandatory; immediately after the Characteristic declaration).
- Zero or more *Characteristic Descriptor* declarations.

Characteristic declaration macros

The following macros are used to declare Characteristics:

- *CHARACTERISTIC (name, uuid16, properties)*
- *CHARACTERISTIC_UUID32 (name, uuid32, properties)*
- *CHARACTERISTIC _UUID128 (name, uuid128, properties)*

See Service declaration for *uuidXXX* parameter explanation.

The *properties* parameter is a bit mask. The flags are defined in the *gattCharacteristicPropertiesBitFields_t*.

Parent topic: Declaring a characteristic

Declaring characteristic values

The Characteristic Value declaration immediately follows the Characteristic declaration and uses one of the following macros:

- *VALUE (name, uuid16, permissions, valueLength, valueByte1, valueByte2, ...)*
- *VALUE_UUID32 (name, uuid32, permissions, valueLength, valueByte1, valueByte2, ...)*
- *VALUE _UUID128(name, uuid128, permissions, valueLength, valueByte1, valueByte2, ...)*
  - See Declaring a service for description of the *uuidXXX* parameter.
  - The *permissions* parameter is a bit mask, whose flags are defined in *gattAttributePermissionsBitFields_t* .
  - The *valueLength* is the number of bytes to be allocated for the Characteristic Value. After this parameter, exactly [*valueLength*] bytes follow in 0xZZ format, representing the initial value of this Characteristic.

These macros are used to declare Characteristic Values of *fixed lengths*.

Some Characteristics have *variable length values*. For those, the following macros are used:

- *VALUE_VARLEN (name, uuid16, permissions, maximumValueLength, initialValueLength, valueByte1, valueByte2, ...)*
- *VALUE_UUID32_VARLEN (name, uuid32, permissions, maximumValueLength, initialValueLength, valueByte1, valueByte2, ...)*
- *VALUE_UUID128_VARLEN (name, uuid128, permissions, maximumValueLength, initialValueLength, valueByte1, valueByte2, ...)*
  - The number of bytes allocated for this Characteristic Value is *maximumValueLength*.
  - The number of *valueByteXXX* parameters shall be equal to *initialValueLength*.

Obviously, *initialValueLength* is, at most, equal to *maximumValueLength*.

Parent topic: Declaring a characteristic

Declaring characteristic descriptors

Characteristic's Descriptors are declared after the Characteristic Value declaration and before the next Characteristic declaration.

The macros used to declare Characteristic Descriptors are very similar to those used to declare fixed-length Characteristic Values:

- *DESCRIPTOR (name, uuid16, permissions, descriptorValueLength, descriptorValueByte1, descriptorValueByte2, ...)*
- *DESCRIPTOR_UUID32 (name, uuid32, permissions, descriptorValueLength, descriptorValueByte1, descriptorValueByte2, ...)*

- *DESCRIPTOR_UUID128(name, uuid128, permissions, descriptorValueLength, descriptorValueByte1, descriptorValueByte2, ...)*

A special Characteristic Descriptor that is used very often is the *Client Characteristic Configuration Descriptor (CCCD)*. This is the descriptor where clients write some of the bits to activate Server notifications and/or indications. It has a reserved, 2-byte, SIG-defined UUID (0x2902), and its attribute value consists of only 1 byte (out of which 2 bits are used for configuration, the other 6 are reserved).

Because the CCCD appears very often in Characteristic definitions for standard Bluetooth Low Energy profiles, a special macro is used for CCCD declaration:

- *CCCD (name)*

This simple macro is basically equivalent to the following Descriptor declaration:

```
* DESCRIPTOR \(name, *
   *0x2902, *
   (gGattAttPermAccessReadable_c
   | gGattAttPermAccessWritable_c),
   2, 0x00, 0x00)
```

Parent topic: Declaring a characteristic

Parent topic: Creating static GATT database

Static GATT database definition examples

The GAP Service must be present on any GATT Database. It has the Service UUID equal to 0x1800, *«GAP Service»*, and it contains three read-only Characteristics, no authentication required: *Device Name, Appearance,*and *Peripheral Preferred Connection Parameters*. These also have well defined UUIDs in the SIG documents.

Most of the demos also include the optional GATT Security Levels characteristic, which defines the highest security requirements of the GATT server when operating in a LE connection.

The definition for this Service is shown here:

```
PRIMARY_SERVICE(service_gap, 0x1800)
   CHARACTERISTIC(char_device_name, 0x2A00, (gGattCharPropRead_c) )
       VALUE(value_device_name, 0x2A00, (gGattAttPermAccessReadable_c), 6, “Sensor”)
   CHARACTERISTIC(char_appearance, 0x2A01, (gGattCharPropRead_c) )
      VALUE(value_appearance, 0x2A01, (gGattAttPermAccessReadable_c), 2,
       0xC2, 0x03)
   CHARACTERISTIC(char_ppcp, 0x2A04, (gGattCharPropRead_c) )
       VALUE(value_ppcp, 0x2A04, (gGattAttPermAccessReadable_c), 8, 0x0A,
       0x00, 0x10, 0x00, 0x64, 0x00, 0xE2, 0x04)
   CHARACTERISTIC(char_security_levels, gBleSig_GattSecurityLevels_d,
      (gGattCharPropRead_c) )
       VALUE(value_security_levels, gBleSig_GattSecurityLevels_d,
       (gPermissionFlagReadable_c), 2, 0x01, 0x01)
```

Another often encountered Service is the Scan Parameters Service:

```
PRIMARY_SERVICE(service_scan_parameters, 0x1813)
      CHARACTERISTIC(char_scan_interval_window, 0x2A4F,           (gGattCharPropWriteWithoutRsp_
↪c) )
       VALUE(value_scan_interval_window, 0x2A4 (gGattAttPermAccessWritable), 4, 0x00, 0x00, 0x00,␣
↪0x00)
       CHARACTERISTIC(char_scan_refresh, 0x2A31, (gGattCharPropRead_c gGattCharPropNotify_c) )
       VALUE(value_scan_refresh, 0x2A31, (gGattAttPermAccessReadable_c), 1, 0x00) CCCD(cccd_scan_
↪refresh)
```

Note: All “user-friendly” names given in declarations are statically defined as *enum* members, numerically equal to the *attribute handle* of the declaration. This means that one of those names

can be used in code wherever an attribute handle is required as a parameter of a function if *gatt_db_handles.h* is included in the application source file. For example, to write the value of the Scan Refresh Characteristic from the application-level code, use these instructions:

```
#include "gatt_db_handles.h"
...
uint8_t scan_refresh_value = 0x12;
GattDb_WriteAttribute(char_scan_refresh, 1, &scan_refresh_value);
```

For static database declarations, the 'attribute handle' is equal to the line number in the gatt_fb.h file, where the attribute is defined.

Parent topic: Creating static GATT database

Parent topic:*Creating GATT database*

Creating a GATT database dynamically

To define a GATT Database at runtime, the *gGattDbDynamic_d* macro must be defined in *app_preinclude.h* with the value equal to 1.

Then, the application must use the APIs provided by the *gatt_db_dynamic.h* interface to add and remove Services and Characteristics as needed.

See Creating static GATT database for a detailed description of Service and Characteristic parameters.

Memory considerations

The GATT Dynamic database module internally manages the memory allocation for the database. There are two ways to specify the memory configuration. The selection is done by setting gGattDynamicAttrSize_c and/or gGattDynamicValSize_c.

- *Statically pre-allocated memory area*
  - gGattDynamicAttrSize_c - the total size of the table of characteristics
  - gGattDynamicValSize_c - the total size of the values cumulated from all characteristics. If any of these macros is greater than 1 the application is responsible to decide upon the best value. In case the selected value is not big enough gBleOutOfMemory_c is returned by the GATT API calls.
- *Dynamic allocated memory area* If the gMemManagerLightExtendHeapAreaUsage define is set to 1 in the desired application, the whole available heap is used. In such as case, the user does not have to allocate space for the dynamic database. If this is not done, the user only needs to make sure that the MinimalHeapSize_c define is set to a high enough value considering all attributes and attribute values they want to add to the database, as well as other memory requirements the application might have. This method is used in case only several attributes are added dynamically. If multiple attributes are needed the method from *Statically pre-allocated memory area* above is recommended. This is because the heap gets fragmented with each adding of a new attribute.

Internally, two buffers are used by the dynamic database module: an attribute buffer and a value buffer. The attribute buffer size increases with the addition of each attribute to the database. The value buffer size increases depending on the UUID type and value lengths required by the application. The two buffers start with a minimum size and are reallocated whenever new requests to add entries are received and there is not enough available memory left. If the user removes these entries from the database, the memory reserved for those entries is not freed, but shifted, leaving room for new entries. Thus, an add operation after a remove operation might not necessarily reallocate the buffer if the new entries fit. The two buffers used by the Dynamic database module will not be available to the application until the user releases the database.

Parent topic: Creating a GATT database dynamically

Initialization and release

Before anything can be added to the database, it must be initialized with an empty collection of attributes.

The *GattDbDynamic_Init()* API is automatically called by the *GattDb_Init()* implementation provided in the *gatt_database.c* source file. Application-specific code does not need to call this API again, unless at some point it destroys the database with *GattDb_ReleaseDatabase()*.

Parent topic: Creating a GATT database dynamically

Adding services

The APIs that can be used to add Services are self-explanatory:

- *GattDbDynamic_AddPrimaryServiceDeclaration*
  - The Service UUID is specified as parameter.

    Memory requirements: one entry in the attribute buffer and UUID size in value buffer.
- *GattDbDynamic_AddSecondaryServiceDeclaration*
  - The Service UUID is specified as parameter.

    Memory requirements: one entry in the attribute buffer and UUID size in value buffer.
- *GattDbDynamic_AddIncludeDeclaration*
  - The Service UUID and handle range are specified as parameters.

    Memory requirements: one entry in the attribute buffer and 6 bytes in value buffer.

The functions have an optional out parameter *pOutHandle*. If its value is not NULL, the execution writes a 16-bit value in the pointed location representing the attribute handle of the added declaration. The application can use this handle as parameter in few *GattDbApp* APIs or in the Service removal functions.

At least one Service must be added before any Characteristic.

Parent topic: Creating a GATT database dynamically

Adding characteristics and descriptors

The APIs for adding Characteristics and Descriptors are enumerated below:

- *GattDbDynamic_AddCharacteristicDeclarationAndValue*
  - The Characteristic UUID, properties, access permissions, and initial value are specified as parameters.
- *GattDbDynamic_AddCharacteristicDeclarationWithUniqueValue*
  - Multiple calls to this API allocate a unique 512-byte value buffer as an optimization for application that deal with large value buffers that do not always need to be stored separately.
- *GattDbDynamic_AddCharacteristicDescriptor*
  - The Descriptor UUID, access permissions and initial value are specified as parameters.
- *GattDbDynamic_AddCccd*
  - Shortcut for a CCCD.

Characteristics and descriptors are automatically added at the end of the database. Thus, a service declaration should be followed by all desired characteristic and descriptor definitions before adding a new service to the database.

Parent topic: Creating a GATT database dynamically

Removing services and characteristics

To remove a Service or a Characteristic, the following APIs may be used, both of which only require the declaration handle as parameter:

- *GattDbDynamic_RemoveService*
- *GattDbDynamic_RemoveCharacteristic*

Parent topic: Creating a GATT database dynamically

Parent topic:*Creating GATT database*

Gatt caching

Service change feature

The **service changed** feature applies to GATT servers and supports the service changed characteristic, dynamic databases, and handle value indications. The GATT clients that require to be notified for structural modifications on the database should write the CCCD of the Service Changed Characteristic on the server. The value of the Service Changed characteristic is represented by 2 handle values for the handle range affected by the modifications.

The changes that trigger a server database modification are represented by the following API calls:

- *GattDbDynamic_AddPrimaryServiceDeclaration*
- *GattDbDynamic_AddSecondaryServiceDeclaration*
- *GattDbDynamic_AddIncludeDeclaration*
- *GattDbDynamic_AddCharacteristicDeclarationAndValue*
- *GattDbDynamic_AddCharDescriptor*
- *GattDbDynamic_AddCccd*
- *GattDbDynamic_RemoveService*
- *GattDbDynamic_RemoveCharacteristic*

Those GATT server API calls update two internal handles to memorize the minimum and maximum range affected by the change.

After the GATT server database update is done, the application must call the GattDbDynamic_EndDatabaseUpdate() API. After this, a Service Changed indication is internally sent to each connected peer that has enabled these indications. The indication contains the handle range affected by the change.

. For bonded devices with whom the server is not currently in an active connection, the changes are buffered on the server and the peers are notified upon reconnection.

Parent topic: Gatt caching

Robust caching

Robust caching is a feature where the server sends an error response to the client if the server does not consider the client to be aware of a database structural change. A server supporting robust caching provides the Client Supported Features, Database Hash, and Service Changed characteristics. To indicate support for robust caching, clients should write the robust caching bit (bit 0) of the Client Supported Features characteristic on the server. An example of the GAP service definition for a server with robust caching support is the following:

- *PRIMARY_SERVICE(service_gatt, gBleSig_GenericAttributeProfile_d)*
- *CHARACTERISTIC(char_service_changed, gBleSig_GattServiceChanged_d, (gGattCharPropIndicate_c))*

- *VALUE(value_service_changed, gBleSig_GattServiceChanged_d, (gPermissionNone_c), 4, 0x01, 0x00, 0xFF, 0xFF)*
- *CCCD(cccd_service_changed)*
- *CHARACTERISTIC(char_client_supported_features, gBleSig_GattClientSupportedFeatures_d, (gGattCharPropRead_c | gGattCharPropWrite_c))*
- *VALUE(value_client_supported_features, gBleSig_GattClientSupportedFeatures_d, (gPermissionFlagReadable_c | gPermissionFlagWritable_c), 8, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00)*
- *CHARACTERISTIC(char_database_hash, gBleSig_GattDatabaseHash_d, (gGattCharPropRead_c))*
- *VALUE(value_database_hash, gBleSig_GattDatabaseHash_d, (gPermissionFlagReadable_c), 16, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00)*

The Client Supported Features characteristic should be declared as an array. The array size is equal to the maximum number of connections, which can be active at one time, so that each possible peer can have its own value. The Server Supported Features characteristic value is automatically written by the Host to indicate robust caching support when appropriate. The Database Hash characteristic value is a 128-bit unsigned integer number where the computed hash value is written.

In order to enable the Robust Caching feature, the *gGattCaching_d* define should be enabled in the file app_preinclude.h. In order to enable automatic Host support for Robust Caching, the *gGattAutomaticRobustCachingSupport_d*define should also be enabled. This includes writing the Client Supported Features characteristic, writing the CCCD of the Service Changed characteristic, and reading the Database Hash after reconnecting with a previously bonded peer to check for new changes. If this define is not enabled, then it is up to the application to read and write all necessary characteristic for Robust Caching support.

The client state is kept on the server using the following enum:

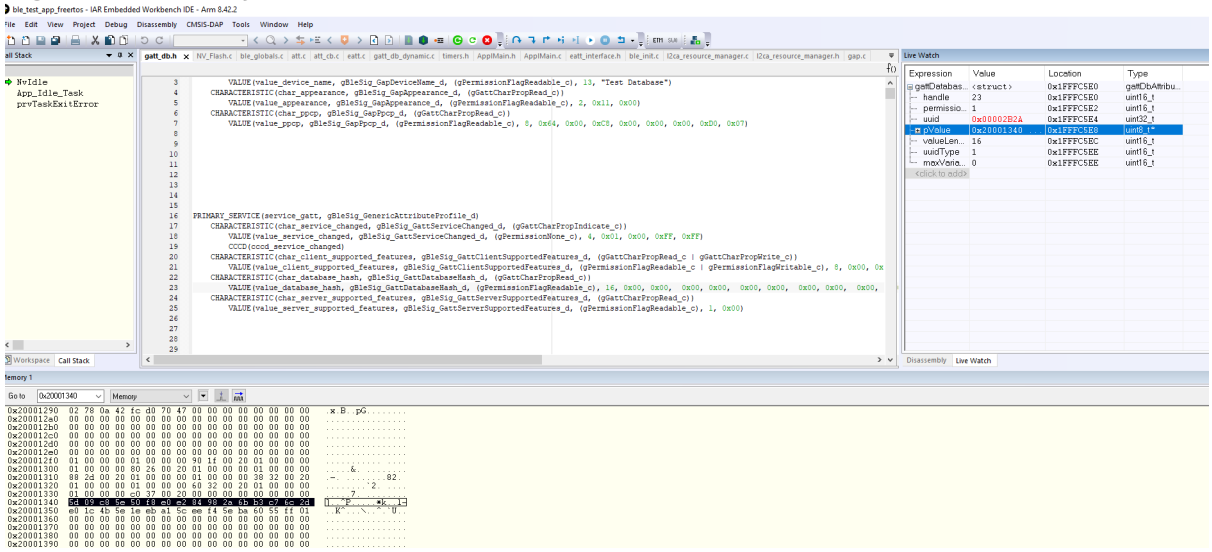
```
typedef enum
{
gGattClientChangeUnaware_c = 0x00U, /*!< Gatt client state */
gGattClientStateChangePending_c = 0x01U, /*!< Gatt client state */
gGattClientChangeAware_c = 0x02U, /*!< Gatt client state */
} gattCachingClientState_c;
```

The initial state of a client without a trusted relationship is change-aware. The state of a client with a trusted relationship remains unchanged from the previous connection. However, in cases where the database has been updated since the last connection, the initial state is change-unaware. When a database update occurs, all connected clients become change unaware.

If a change-unaware client sends an ATT command, the server ignores it. For ATT requests received from a change-unaware client, the server sends an error response with the error code set to *gAttErrCodeDatabaseOutOfSync_c*. The server should also not send indications and notifications to change unaware clients, except for the Service Changed indication. The state of a client is verified by the GATT server before executing each command, request or sending any notifications or indications.

The following PDU types are an exception to this rule and do not generate an gAttErrCodeDatabaseOutOfSync_c error code:

- ATT_FIND_INFORMATION_REQ
- ATT_FIND_BY_TYPE_VALUE_REQ
- ATT_READ_BY_GROUP_TYPE_REQ
- ATT_EXECUTE_WRTIE



For a change unaware client to become change aware again, one of the following must happen:

- The client receives and confirms a Service Changed Indication.
- The server, upon receiving a request from a change unaware client, sends the client a response with the error code set to Database Out Of Sync and then the server receives another ATT request from the client.
- The change unaware client reads the Database Hash characteristic and then the server receives another ATT request from the client.

The function *GattDb_ComputeDatabaseHash()* is used by the server to compute the hash value and save its value in the database. The computation is done when a read request for the database hash characteristic is first received from a peer GATT client for dynamic databases.

For static databases, hash computation is disabled by default. If you have a static database and want to compute the database hash, then declare the following define to TRUE in app_preinclude.h: *gGattDbComputeHash_d*. By doing this, the hash value is computed during the host initialization. The value is written directly to the database as characteristic and it can be viewed in the memory, as see in the image below. Since static databases do not change in structure over time, this value remains constant, so it can be saved separately and written manually to memory if needed. See Figure 10 below.

Figure 10. Memory view of the Database Hash characteristic

On the client side, the *GattClient_GetDatabaseHash()* function is used to read the hash value from a peer GATT server. If the *gGattAutomaticRobustCachingSupport_c* define is enabled, then the following steps are executed automatically:

- Writing the Client Supported Features characteristic value to indicate robust caching support – set BIT0 to 1.
- Write the CCCD of the Service Changed characteristic.
- Read the initial value of the Database Hash characteristic and store it locally.

Otherwise, just the read request for the Database Hash characteristic is sent to the peer.

The following arrays and variables are used for the implementations of the robust caching and service changed features (declared in ble_globals.c):

```
/* Service changed indication buffer */
   gattHandleRange_t gServiceChangedIndicationStorage[gMaxBondedDevices_c];

/* client saved values for service changed characteristic and CCCD handles */
   uint16_t mActiveServiceChangedCharHandle[gAppMaxConnections_c] = {gGattDbInvalidHandle_d};
   uint16_t mServiceChangedCharHandle[gMaxBondedDevices_c] = {gGattDbInvalidHandle_d};
```

(continues on next page)

(continued from previous page)

```
    uint16_t mActiveServiceChangedCCCDHandle[gAppMaxConnections_c] = {gGattDbInvalidHandle_d};

/* server values for its own service changed characteristic and CCCD handles */
    uint16_t mServerServiceChangedCharHandle;
    uint16_t mServerServiceChangedCCCDHandle;

/* client state information for bonded and active clients */
    gattCachingClientState_c gGattClientState[gMaxBondedDevices_c] = {gGattClientChangeAware_c};
    gattCachingClientState_c gGattActiveClientState[gAppMaxConnections_c] = {gGattClientChangeAware_
↪c};

/* Database hash values - the client needs a hash value for each possible peer */
    uint8_t mGattActiveServerDatabaseHash[gGattDatabaseHashSize_c * gAppMaxConnections_c] = {0};
    uint8_t mGattServerDatabaseHash[gGattDatabaseHashSize_c * gMaxBondedDevices_c] = {0};

/* client supported features handles for active gatt servers */
    uint16_t gGattActiveClientSupportedFeaturesHandles[gAppMaxConnections_c] =
↪{gGattDbInvalidHandle_d};

/* client supported features information for bonded gatt clients */
    uint8_t gGattClientSupportedFeatures[gMaxBondedDevices_c] = {0U};

/* index of the database hash characteristic in the database */
    uint32_t mServerDatabaseHashIndex = gGattDbInvalidHandleIndex_d;

/* index of the client supported features characteristic in the database */
    uint32_t mServerClientSupportedFeatureIndex = gGattDbInvalidHandleIndex_d;
```

It is up to the application to save a local copy of the information from the server's database and to initiate service discovery only on the first connection or when it is informed of a change by the peer using Service Changed and Robust Caching.

If the *gGattAutomaticRobustCachingSupport_c* define is not set, it is up to the application to check the Server Supported Features characteristic value on the peer, to write the Client Supported Features characteristic value and to write the Service Changed CCCD.

Two new GATT procedures are introduced as part of the Robust Caching feature. Both should be treated according to the application needs in the GATT procedure callback of the application.

- *gGattProcSignalServiceDiscoveryComplete_c –*informs the application that the service discovery procedure has finished after reading the Database Hash value using the read using characteristic UUID procedure. The application procedure callback should call *BleServDisc_Finished()*on this event when robust caching is supported.
- *gGattProcUpdateDatabaseCopy_c –*informs the application that its database copy is no longer up to date and service discovery should be reperformed. Used when the client received an error response with the *gAttErrCodeDatabaseOutOfSync_c* opcode, when the local database hash value is found to be out of sync with the one on the server, or when a service changed indication is received from the server.

If service discovery is performed using our ble_service_discovery module, then the application should wait for the *gDiscoveryFinished_c* event before initiating its own GATT procedures. The application should also make sure to not initiate a second GATT procedure which requires a response from the peer before receiving a response to the first request it made.

Parent topic:*Creating GATT database*

Creating a Custom Profile

This chapter describes how the user can create customizable functionality over the Bluetooth Low Energy Host Stack by defining profiles and services. The Temperature Profile, used by the

Temperature Sensor and Collector applications, is used as a reference to explain the steps of building custom functionality.

Defining custom UUIDs

The first step when defining a new service included in a profile is to define the custom 128-bit UUID for the service and the included characteristics. These values are defined in *gatt_uuid128.h*, which is located in the application folder. For example, the Temperature Profile uses the following UUID for the service:

```
/* Temperature */
UUID128(uuid_service_temperature, 0xfb ,0x34 ,0x9b ,0x5f ,0x80 ,0x00, 0x00, 0x80, 0x00, 0x10, 0x00, 0x02,␣
↪0x00, 0xfe, 0x00, 0x00)
```

The definition of the services and characteristics are made in *gattdb.h*, as explained in *Creating GATT database*. For more details on how to structure the database, see *Application Structure*.

Parent topic:*Creating a Custom Profile*

Creating service functionality

All defined services in the SDK have a common template which helps the application to act accordingly.

The service locally stores the device identification for the connected client. This value is changed on subscription and non-subscription events.

```
/*! Temperature Service - Subscribed Client*/
static deviceId_t mTms_SubscribedClientId;
```

The service is initialized and changed by the application through a service configuration structure. It usually contains the service handle, initialization values for the service (for example, the initial temperature for the Temperature Service) and in some cases user-specific structures that can store saved measurements (for example, the Blood Pressure Service). Below is an example for the custom Temperature Service:

```
/*! Temperature Service - Configuration */
typedef struct tmsConfig_tag
{
    uint16_t serviceHandle ;
    int16_t initialTemperature ;
} tmsConfig_t ;
```

The initialization of the service is made by calling the start procedure. The function requires as input a pointer to the service configuration structure. This function is usually called when the application is initialized. It resets the static device identification for the subscribed client and initializes both dynamic and static characteristic values. An example for the Temperature Service (TMS) is shown below:

```
bleResult_t Tms_Start ( tmsConfig_t *pServiceConfig)
{
    mTms_SubscribedClientId = gInvalidDeviceId_c;
    return Tms_RecordTemperatureMeasurement (pServiceConfig-> serviceHandle ,
                                             pServiceConfig-> initialTemperature );
}
```

The service subscription is triggered when a device connects to the server. It requires the peer device identification as an input parameter to update the local variable. On disconnect, the unsubscribe function is called to reset the device identification. For the Temperature Service:

```
bleResult_t Tms_Subscribe ( deviceId_t deviceId)
{
    mTms_SubscribedClientId = deviceId;
    return gBleSuccess_c;
}
bleResult_t Tms_Unsubscribe (void)
{
    mTms_SubscribedClientId = gInvalidDeviceId_c;
    return gBleSuccess_c;
}
```

Depending on the complexity of the service, the API implements additional functions. For the Temperature Service, there is only a temperature characteristic that is notifiable by the server. The API implements the record measurement function which saves the new measured value in the GATT database and send the notification to the client device if possible. The function needs the service handle and the new temperature value as input parameters:

```
bleResult_t Tms_RecordTemperatureMeasurement ( uint16_t serviceHandle, int16_t temperature)
{
    uint16_t handle;
    bleResult_t result;
    bleUuid_t uuid = Uuid16(gBleSig_Temperature_d);
    /* Get handle of Temperature characteristic */
    result = GattDb_FindCharValueHandleInService(serviceHandle,
        gBleUuidType16_c, &uuid, &handle);
    if (result != gBleSuccess_c)
        return result;
    /* Update characteristic value */
    result = GattDb_WriteAttribute(handle, sizeof( uint16_t ), ( uint8_t *)&temperature);
    if (result != gBleSuccess_c)
        return result;
    Hts_SendTemperatureMeasurementNotification(handle);
    return gBleSuccess_c;
}
```

To accommodate some use cases where the service is reset, the stop function is called. The reset also implies a service unsubscribe. Below is an example for the Temperature Service:

```
bleResult_t Tms_Stop ( tmsConfig_t *pServiceConfig)
{
    return Tms_Unsubscribe();
}
```

Parent topic:*Creating a Custom Profile*

GATT client interactions

The client side of the service, which includes the service discovery, notification configuration, attribute reads and others are left to be handled by the application. The application calls the GATT client APIs and reacts accordingly. The only exception for this rule is that the service interface declares the client configuration structure. This structure usually contains the service handle and the handles of all the characteristic values and descriptors discovered. Additionally it can contain values that the client can use to interact with the server. For the Temperature Service client, the structure is as follows:

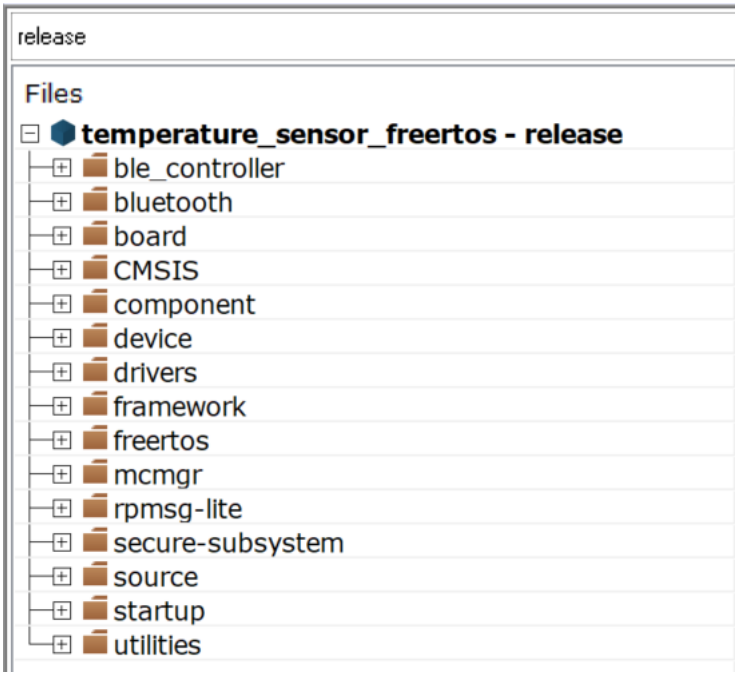
```
/*! Temperature Client - Configuration */
typedef struct tmcConfig_tag
{
    uint16_t            hService;
    uint16_t            hTemperature ;
    uint16_t            hTempCccd ;
```

(continues on next page)

(continued from previous page)

```
    uint16_t                hTempDesc ;
    gattDbCharPresFormat_t  tempFormat ;
} tmcConfig_t ;
```

Parent topic:*Creating a Custom Profile*



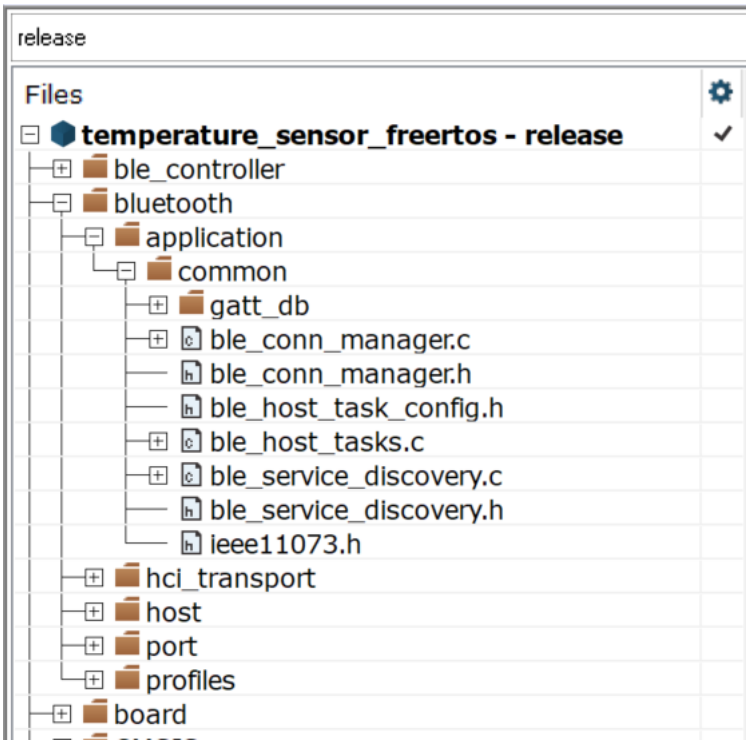
Application Structure

This chapter describes the organization of the Bluetooth Low Energy demo applications that can be found in the SDK. By familiarizing with the application structure, the user is able to quickly adapt its design to an existing demo or create a new application.

The Temperature Sensor application is used as a reference to showcase the architecture.

Folder structure

The Figure shows the application folder structure.

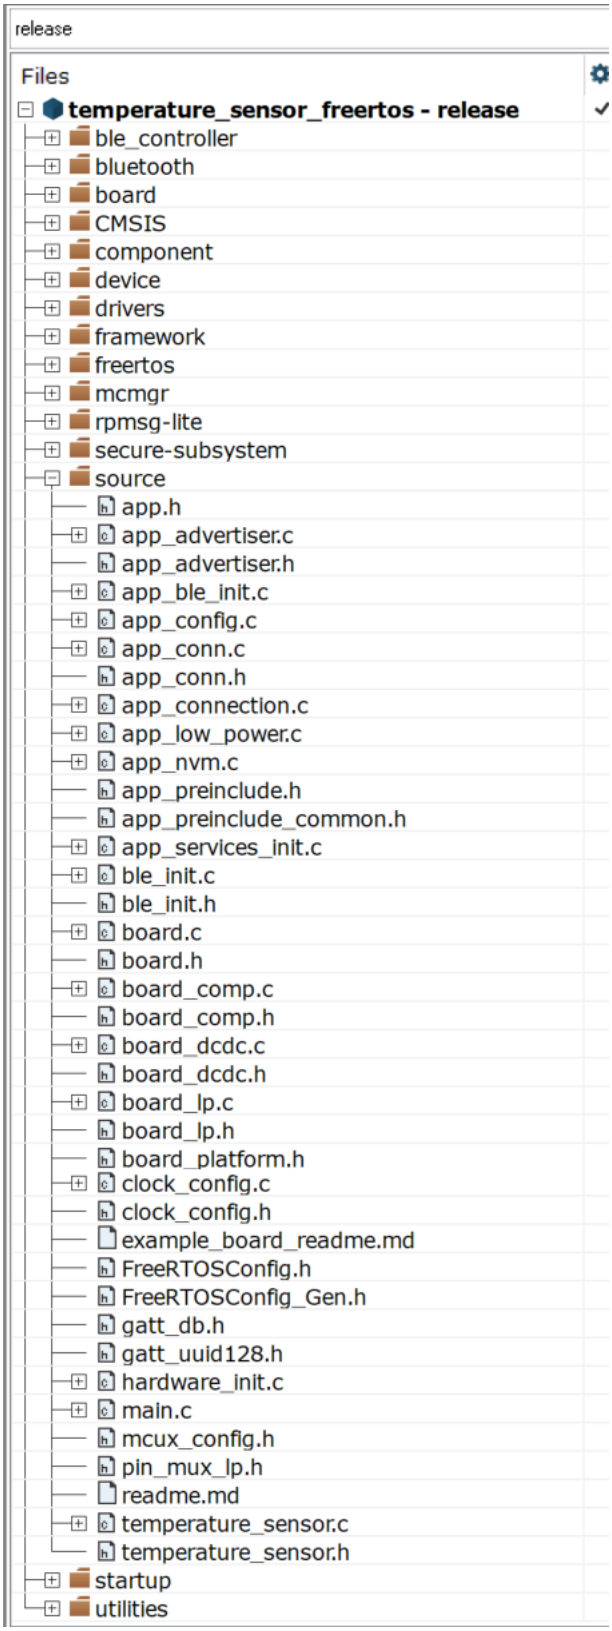


Application Folder structure in workspace

The *app* folder follows a specific structure which is recommended for any application developed using the Bluetooth Low Energy Host Stack:

- The *common* group contains the application framework shared by all profiles and demo applications:
  - Bluetooth Low Energy Connection Manager
  - Bluetooth Service Discovery Manager
  - Bluetooth Low Energy Stack and Task Initialization and Configuration
  - GATT Database

Common Group

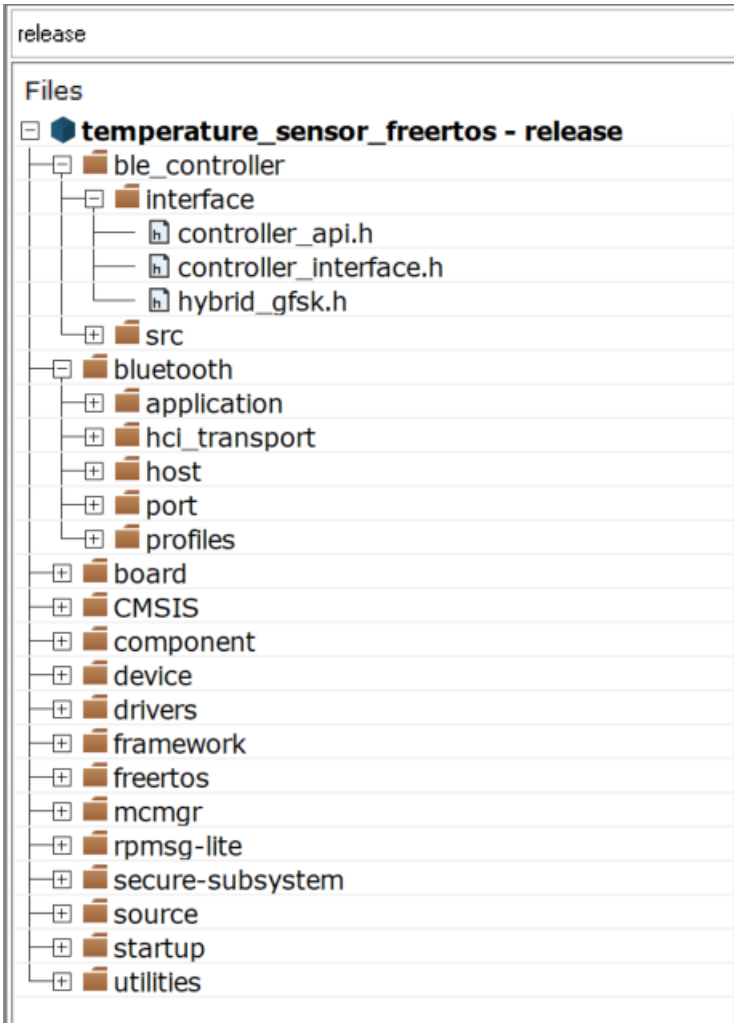


- The *source* group contains code specific to the Temperature Sensor application.

  In the following examples, *app.c* is used as a placeholder for the main application source file. In the case of Temperature Sensor, it is *temperature_sensor.c*.

  The source group also contains files which aid with the handling of Host events and framework related functionality. These are: *app_conn.c*/*app_conn.h*, *app_advertiser.c*, *app_connection.c*, *app_scanner.c*, *app_nvm.c*, and *app_low_power.c*. These files do not allow the application to implement its own state machines, unless application-specific functionality is required. For example, the application is restricted from setting advertising parameters and starting advertising, unless certain application-specific functionalities, such as UI related updates are required.

Source Group



The *bluetooth* folder/group contains:

- The *host/interface*, and *host/config*. These are public interfaces and configuration files for the Host. The functionality is included in the library located in the *host/lib* subfolder. The folder is not shown in the IAR project structure, but added into the toolchain linker settings under the library category.
- *bluetooth/profiles* contains profile-specific code; it is used by each demo application of stan-

dard profiles.

The *ble_controller* folder/group contains:

- The *controller/interface*. These are public interfaces and configuration files for the Controller.

Bluetooth and Controller Groups

The framework and component folders/groups contain framework components used by the demo applications. For additional information, see the *Connectivity Framework Reference Manual*.

The *freertos* folder contains sources for the supported operating system.

Parent topic:*Application Structure*

Application main framework

The Application Main module contains common code used by all the applications, such as:

- The Main Task
- Messaging framework between the Bluetooth LE Host Stack Task and the Application Task

Start task

The Start Task (*start_task*) is the first task created by the operating system and is also the one that initializes the rest of the system. It initializes framework components (Memory Manager, Timers Manager etc.) and it calls *BluetoothLEHost_AppInit* from *app.c*, which is used to initialize the Bluetooth LE Host Stack as well as peripheral drivers specific to the implemented application.

The function calls *BluetoothLEHost_HandleMessages*, which represents the Application Task and is used to process events and messages from the Host Stack.

The stack size and priority of the main task are defined in *fsl_os_abstraction_config.h*:

```
#ifndef gMainThreadStackSize_c
#define gMainThreadStackSize_c 1024
#endif
#ifndef gMainThreadPriority_c
#define gMainThreadPriority_c 7
#endif
```

Parent topic: Application main framework

Application messaging

The module contains a wrapper that is used to create messages for events generated by the Bluetooth LE Host Stack in the Host Task context. The wrapper also sends them to be processed by the application in the context of the Application Task.

For example, connection events generated by the Host are received by *App_ConnectionCallback*. The function creates a message, places it in the Host to Application queue and signals the Application with *gAppEvtMsgFromHostStack_c*. The Application Task de-queues the message and calls *App_HandleHostMessageInput*, which calls the corresponding callback implemented the application-specific code (*app.c*), in this example: *BleApp_ConnectionCallback*.

It is strongly recommended that the application developer uses the *app.c* module to add custom code on this type of callbacks.

Parent topic: Application main framework

Parent topic:*Application Structure*

Bluetooth LE Connection Manager

The connection manager is a helper module that contains common application configurations and interactions with the Bluetooth LE Host Stack. It implements the following events and methods:

- Host Stack GAP Generic Event
- Host Stack Connection Event on both GAP Peripheral and GAP Central configuration
- Host Stack configuration for GAP Peripheral or GAP Central

GAP generic event

The GAP Generic Event is triggered by the Bluetooth LE Host Stack and sent to the application via the generic callback. Before any application-specific interactions, the Connection Manager callback is called to handle common application events, such as device address storage.

```
void BleApp_GenericCallback ( gapGenericEvent_t * pGenericEvent)
{
    /* Call Bluetooth Low Energy Conn Manager */
    BleConnManager_GenericEvent(pGenericEvent);
    switch (pGenericEvent-> eventType )
    {
        ...
    }
}
```

In the **BleConnManager_GenericEvent** function, local keys are generated.

- The local LTK, IRK, as well as the EDIV and RAND are obtained hashing over the board's UID and stored in RAM as plain-text every time the **gInitializationComplete_c** event is received.
- In **Advanced Secure** mode, local IRK is generated using the EdgeLock Secure Enclave and stored into a dedicated NVM data set as ELKE blobs (40 bytes blob encrypted using unique die key) on the first gInitializationComplete_c event received.

The NBU Decryption key for IRK is generated and distributed to the NBU over the private key bus. The EIRK blob (16 bytes blob which can be decrypted only by NBU hardware using NBU Decryption key for IRK) is generated from the IRK ELKE blob and stored in the RAM to be used for controller privacy on every gInitializationComplete_c event received. For the host privacy, the ELKE IRK blob is used instead. For details, refer to the section "Advanced security capabilities".

Parent topic: Bluetooth LE Connection Manager

GAP configuration

The GAP Central or Peripheral Configuration is used to create common configurations (such as setting the public address, registering the security requirements, adding the addresses of bonded devices in the Controller Filter Accept List), which can be customized by the application afterwards. It is called inside the *BluetoothLEHost_Initialized callback* function, before any application-specific configuration, as shown in the example code below.

```
static void BluetoothLEHost_Initialized()
{
    /* Set common GAP configuration */
    BleConnManager_GapCommonConfig();
    ...
}
```

Parent topic: Bluetooth LE Connection Manager

GAP connection event

The GAP Connection Event is triggered by the Host Stack and sent to the application via the connection callback. Before any application-specific interactions, the Connection Manager callback is called to handle common application events, such as device connect, disconnect or pairing-related requests. It is called inside the registered connection such as shown below:

```
static voidBle App_ConnectionCallback ( deviceId_t peerDeviceId, gapConnectionEvent_t *␣
↪pConnectionEvent)
{
    /* Connection Manager to handle Host Stack interactions */
    BleConnManager_GapPeripheralEvent(peerDeviceId, pConnectionEvent);
    switch (pConnectionEvent-> eventType )
    {
        ...
    }
}
```

It is strongly recommended that the application developer uses the app.c module to add custom code.

Parent topic: Bluetooth LE Connection Manager

Privacy

To enable or disable Privacy, the following APIs may be used:

```
bleResult_t
 BleConnManager_EnablePrivacy(void);
```

```
bleResult_t
 BleConnManager_DisablePrivacy(void);
```

The function BleConnManager_EnablePrivacy calls *BleConnManager_ManagePrivacyInternal* after checking if the privacy is enabled.

```
static bleResult_t
BleConnManager_ManagePrivacyInternal
(bool_t bCheckNewBond);
```

If the privacy feature is supported (*gAppUsePrivacy_d = 1*), the Connection Manager activates Controller Privacy or Host Privacy depending on the board capabilities.

The *bCheckNewBond* is a boolean that tells the Manager whether it should check or not if a bond between the devices already exists.

In order to update the identity information after a bond is added or removed privacy should be disabled and enabled. For pairing with bonding this is done automatically in *ble_conn_manager*. In case the application adds or removes a bond through the GAP API, it should also disable and enable privacy.

Parent topic:*Application Structure*

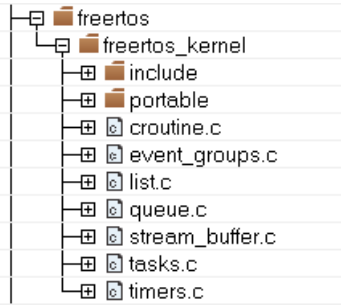
GATT database

The *gatt_db* contains a set of header files grouped in the *macros* subfolder. These macros are used for static code generation for the GATT Database by expanding the contents of the *gatt_db.h* file in different ways. *Creating GATT database* explains how to write the *gatt_db.h* file using user-friendly macros that define the GATT database.

At application compile time, the *gatt_database.c* file is populated with enumerations, structures, and initialization code used to allocate and properly populate the GATT database. In this way, the *gattDatabase*array and the *gGattDbAttributeCount_c* variable (see GATT database) are created and properly initialized.

Note: Do not modify any of the files contained in the *gatt_db* folder and its subfolder.

To complete the GATT database initialization, this demo application includes the required gatt_db.h and gatt_uuid128.h files in its specific application folder, along with other profile-specific configuration and code files.



Parent topic:*Application Structure*

RTOS specifics

Operating system selection

The SDK offers different projects for each supported operating system (FreeRTOS OS) and for BareMetal configuration. To switch between systems, the user needs to switch the workspace.

The RTOS source code is found in the SDK package and is linked in the workspace in the *freertos* virtual folder, as shown in Figure:

Location of FreeRTOS source code in workspace

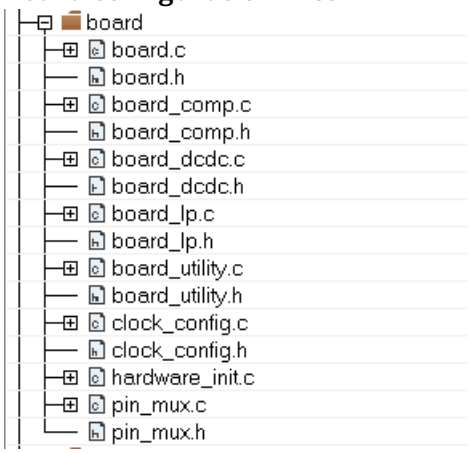
Parent topic:RTOS specifics

Bluetooth LE Host task configuration

Application developers are provided with two files for RTOS task initialization:

- *ble_host_task_config.h*, and *ble_host_tasks.c* for the Host.

Reusing these files is recommended because they perform all the necessary RTOS-related work. The application developer must only modify the macros from **_config.h* files whenever tasks need a bigger stack size or different priority settings. The new values should be overridden in the *app_preinclude.h* file.



Parent topic:RTOS specifics

Parent topic:*Application Structure*

Board configuration

The configuration files for the supported boards can be found in the *board* folder, as shown in Figure. The files contain clock and pin configurations that are used by the drivers. The user can customize the board files by modifying the configuration of the pins and clock source according to his design.

Board configuration files

Parent topic:*Application Structure*

Bluetooth Low Energy initialization

The *ble_init.h* and *ble_init.c* files contain the declaration and the implementation of the following function:

```
bleResult_t Ble_Initialize
(
    gapGenericCallback_t gapGenericCallback
)
{
```

(continues on next page)

(continued from previous page)

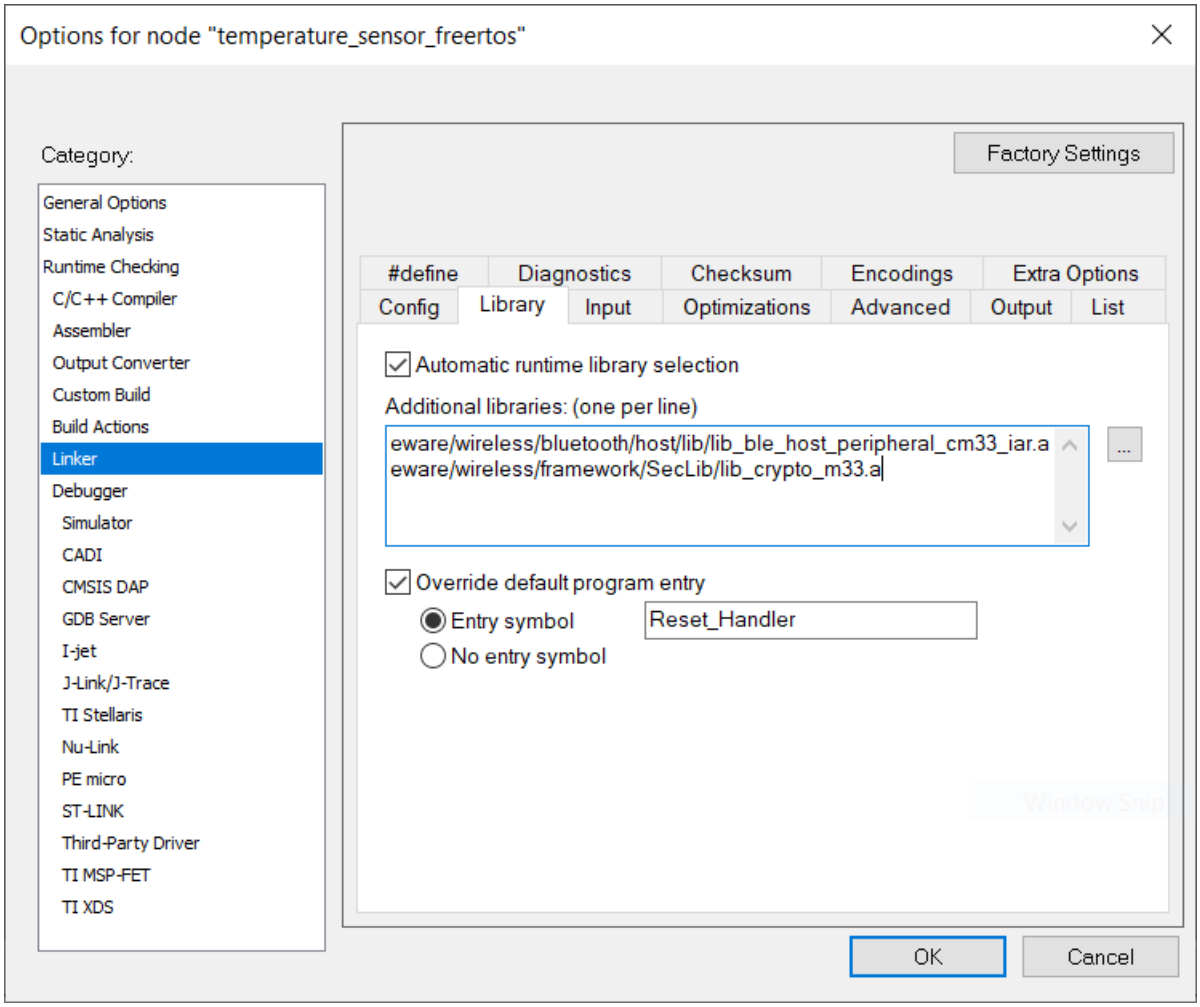
```
#if defined(gUseHciTransportDownward_d) && gUseHciTransportDownward_d
    /* HCI Transport Init */
    if (gHciSuccess_c != Hcit_Init(Ble_HciRecvFromIsr))
    {
        return gHciTransportError_c;
    }

    /*
     * Set BD Address in Controller. Must be done after HCI init
     * and before Host init.
     */
      Ble_SetBDAddr();

    /* Check for available memory storage */
    if (!Ble_CheckMemoryStorage())
    {
        return gBleOutOfMemory_c;
    }
    /* Bluetooth Low Energy Host Tasks Init */
    if (KOSA_StatusSuccess != Ble_HostTaskInit())
    {
        return gBleOsError_c;
    }
    /* Bluetooth Low Energy Host Stack Init */
    return Ble_HostInitialize(gapGenericCallback, Hcit_SendPacket);
#elif defined(gUseHciTransportUpward_d) && gUseHciTransportUpward_d
#else /* gUseHciTransportUpward_d */
#endif /* gUseHciTransportUpward_d */
}
```

Note: This function should be used by your application because it correctly performs all the necessary Bluetooth Low Energy initialization.

Step-by-step analysis is provided below:

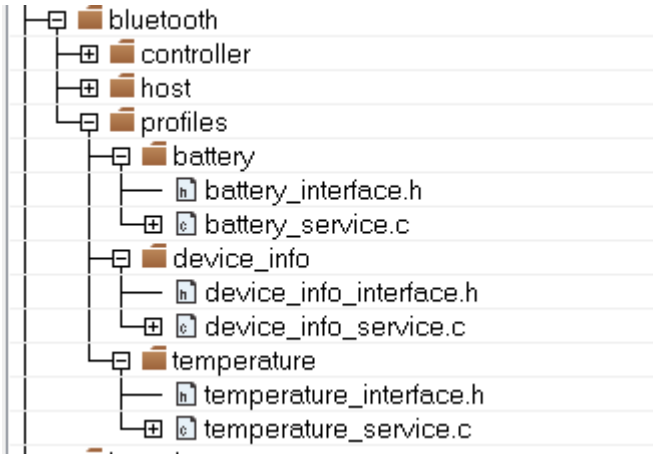


1. First, the HCI interface is initialized by calling *Hcit_Init*. This initializes communication between the Host and the Controller.
2. After setting the BD address into the Controller (Ble_SetBDAddr) and performing memory validation checks (*Ble_CheckMemoryStorage*), the Host task is initialized by calling *Ble_HostTaskInit*.
3. Finally the *Ble_HostInitialize* function initializes the Host with the transport packet transmit function used as the *hciHostToControllerInterface_t parameter*.

Parent topic:*Application Structure*

Bluetooth Low Energy Host Stack configuration

The Bluetooth LE Host Stack libraries are found in the middleware/wireless/bluetooth/host/lib folder. The user should add the best matching library for its use case to the linker options of its project.



For example, the temperature sensor uses the Peripheral Host Stack library, as shown in Figure below:

Parent topic:*Application Structure*

Profile configuration

The implemented profiles and services are located in *middleware/wireless/bluetooth/profiles* folder. The application links every service source file and interface it needs to implement the profile. For example, for the Temperature Sensor the tree looks as shown Figure:

The Temperature Profile implements the custom Temperature service, the Battery, and Device Information services.

Application code

The application folder contains the following modules:

- *app.c* and *app.h*. This module stores the application-specific functionality (APIs for specific triggers, handling of peripherals, callbacks from the stack, handling of low power, and so on).

Before initializing the Bluetooth LE Host Stack, the start task calls *BluetoothLEHost_AppInit*. This function initializes application specific functionality before initializing the Bluetooth LE Host Stack by calling *BluetoothLEHost_Init*.

After the stack is initialized, the *BluetoothLEHost_Initialized* callback is called. The function contains configurations made to the Bluetooth LE Host Stack after the initialization. This includes registering callbacks, setting security for services, starting services, allocating timers, adding devices to the Filter Accept List, and so on. For example, the Temperature Sensor configures the following:

```
static void BluetoothLEHost_Initialized(void)
{
  /* Common GAP configuration */
    BleConnManager_GapCommonConfig();

  /* Register for callbacks*/
    (void)App_RegisterGattServerCallback(BleApp_GattServerCallback);

    mAdvState.advOn = FALSE;

  /* Start services */
    SENSORS_TriggerTemperatureMeasurement();
    (void)SENSORS_RefreshTemperatureValue();
    /* Multiply temperature value by 10. SENSORS_GetTemperature() reports temperature
    value in tenths of degrees Celsius. Temperature characteristic value is degrees
    Celsius with a resolution of 0.01 degrees Celsius (GATT Specification
    Supplement v6). */
    tmsServiceConfig.initialTemperature = (int16_t)(10 * SENSORS_GetTemperature());
    (void)Tms_Start(&tmsServiceConfig);

    basServiceConfig.batteryLevel = SENSORS_GetBatteryLevel();
    (void)Bas_Start(&basServiceConfig);
    (void)Dis_Start(&disServiceConfig);

  /* Allocate application timer */
    (void)TM_Open(appTimerId);

    AppPrintString("\r\nTemperature sensor -> Press switch to start advertising.\r\n");
}
```

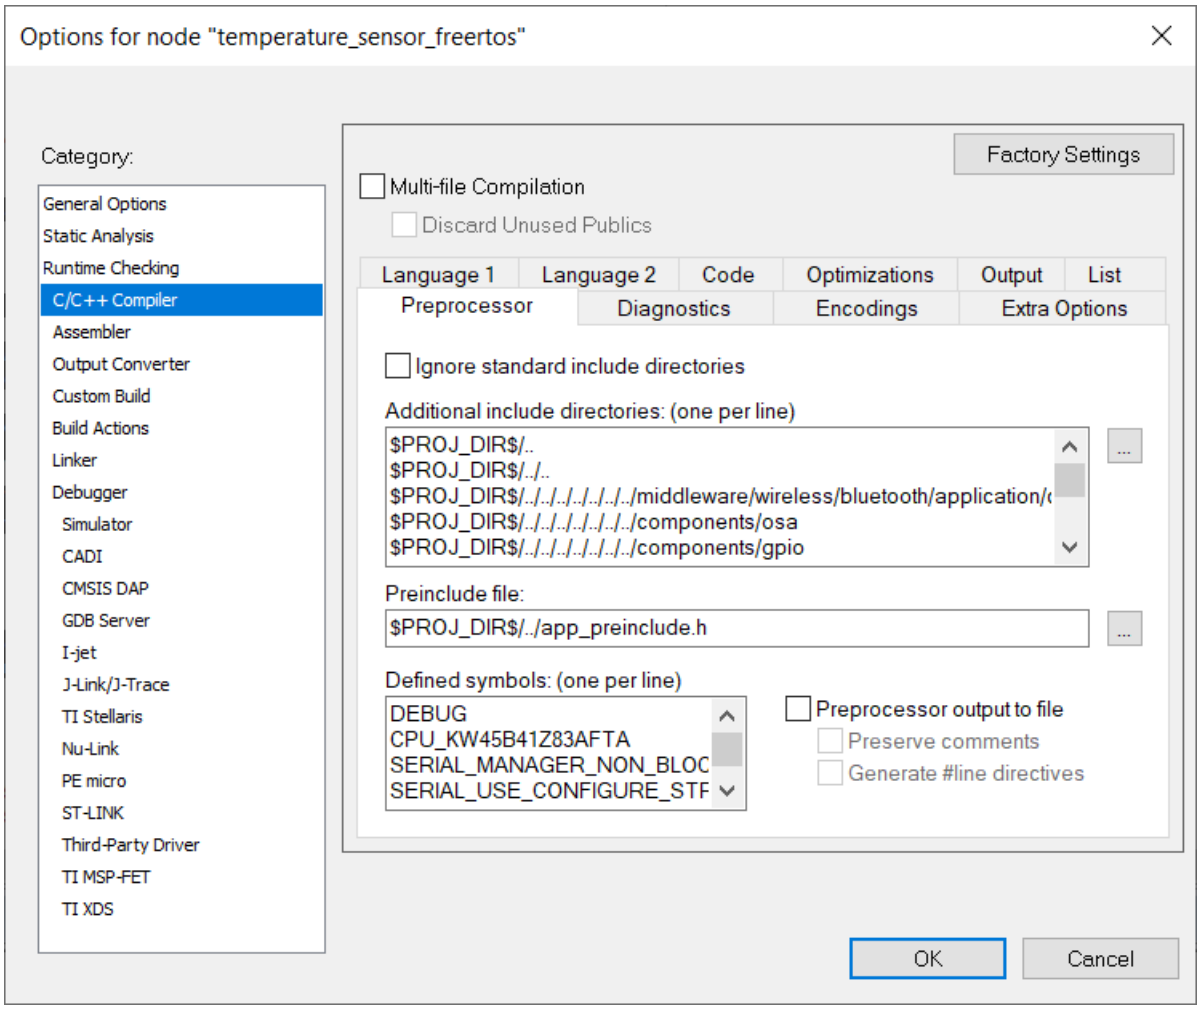
To start the application functionality, BleApp_Start() function is called. This function usually contains code to start advertising for sensor nodes or scanning for central devices. In the example of the Temperature Sensor, the function is the following:

```
static void BleApp_Start(void)
{
    Led1On();

    if (mPeerDeviceId == gInvalidDeviceId_c)
    {
      /* Device is not connected and not advertising */
        if (!mAdvState.advOn)
        {
            /* Set advertising parameters, advertising to start on gAdvertisingParametersSetupComplete_c */
            BleApp_Advertise();
```

(continues on next page)

(continued from previous page)



```
        }
    }
    else
    {
        /* Device is connected, send temperature value */
        BleApp_SendTemperature();
    }
}
```

- *app_config.c.* This file contains data structures that are used to configure the stack.

This includes advertising data, scanning data, connection parameters, advertising parameters, SMP keys, security requirements, and so on.

- *app_preinclude.h.*

This header file contains macros to override the default configuration of any module in the application. It is added as a preinclude file in the preprocessor command line in IAR, as shown in Figure:

- *gatt_db.h* and *gatt_uuid128.h.* The two header files contain the definition of the GATT database and the custom UUIDs used by the application. See *Creating GATT database* for more information.

Parent topic: Profile configuration

Parent topic:*Application Structure*

Multiple connections

Applications can be configured to support multiple connections. To allow multiple connections, the *gAppMaxConnections_c* must be set to a value up to the maximum number of connections (*this value is chip-specific*). Refer to the chip documentation for the supported number of connections.

The application can save information about the peer devices it connects to according to the value of *gAppMaxConnections_c*. The Bluetooth Low Energy profile associated with the application use case must be instantiated to support the use of its functionality for each peer device. When handling multiple connections, the applications can behave as either the GAP central, GAP peripheral, or both at the same time. It is up to the application code to decide whether to start the advertising or scanning before creating the next connection. The supported combinations enable a device to connect as a peripheral to multiple centrals, as a central to multiple peripherals, or for it to be a central for some peers and a peripheral to others. The demo applications provide this functionality as an example of exercising multiple connection support. In such applications, the GAP role can be changed from central to peripheral and the information is saved for each peer device.

Parent topic:*Application Structure*

Bluetooth address generation

BD_ADDR is represented by 48 bits that uniquely identify a device and consist of a 24-bit OUI (Organizationally Unique Identifier) and a 24-bit random part that varies between devices. There are multiple options of storing and using the BD_ADDR. Depending on the chip, it may be read from a device specific register (if supported), from the global hardware parameters stored in the flash, or generated randomly based on the processor-unique identifier. The demo applications provide a combination of the last two options. The *Ble_SetBDAddr* function is called during the initialization process, after initializing HCI and before initializing the Bluetooth LE Host Stack. The global hardware parameters are read from the flash. If a useful value is found, it is used as the BD address. If the found value is all 0xFFs, an address is generated by concatenating the OUI configured at compile time with three randomly generated bytes. The result is stored in the hardware parameters for future use and then set into the Controller. The Bluetooth LE Host Stack uses little-endian format to represent all addresses, in compliance with the Bluetooth Core Specification.

Parent topic:*Application Structure*

Repeated attempts

Applications can be configured to enable protection against repeated Pairing Requests/Peripheral Security Requests coming from the same device. This is to prevent an intruder from repeating the pairing process with a large number of different keys in order to extract information about the local device's private key. If this feature is enabled, after a pairing procedure fails, another attempt to pair coming from the same device is allowed only after a specific time period has passed. For each failure, the waiting period doubles up until a maximum period.

The following *app_preinclude.h* macros support this feature:

- gRepeatedAttempts_d
  - Set to 1 to enable the feature. By default, it is disabled (0).
- gRepeatedAttemptsNoOfDevices_c
  - Number of remote devices to keep track of. By default, the value is 4.
  - If a new device needs to be added and the list is full, one of the oldest entries will be replaced.
- gRepeatedAttemptsTimeoutMin_c

  - Minimum waiting period in seconds – default 10.

- gRepeatedAttemptsTimeoutMax_c
  - Maximum waiting period in seconds – default 640. The waiting period doubles after each failed pairing with the same device.

Parent topic:*Application Structure*

Advanced Secure Mode

This section describes the advanced security capabilities of the Bluetooth LE Host Stack which are available on the KW45/KW47/MCXW72/KW43 platform via the EdgeLock Secure Enclave (ELKE).

The security capabilities are enabled at application, Host and Controller level by setting Advanced Secure Mode to active. To do this, the user must set the *gAppSecureMode_d* macro to *1* in the project's *app_preinclude.h* file. This macro is defined by default as *0* in *app_preinclude_common.h*:

```
#if (gAppSecureMode_d == 1U)
#define gHostSecureMode_d               (1U)
#else
#define gHostSecureMode_d               (0U)
#endif
```

At application level, when Advanced Secure Mode is enabled, the security mode and level for pairing is automatically enforced as Mode 1 Level 4, ensuring LE Secure Connections pairing. Legacy pairing is not supported in this mode.

When enabled, the main benefit of Advanced Secure Mode is the secured storage and handling of Bluetooth LE security keys. The EdgeLock Secure Enclave is capable of generating, importing, and exporting security keys as plain text or as encrypted blobs. All encrypted blobs are created by the EdgeLock Secure Enclave using a die unique key, which makes them impossible to decrypt by devices other than the one that created them. The Bluetooth LE security keys are managed in Advanced Secure Mode as follows:

- IRK
  - The peer IRKs received after pairing and bonding are no longer stored into NVM as plaintext, but as encrypted blobs 40 bytes in length (or ELKE blobs). They can still be retrieved and converted to plaintext.
  - The local IRK is no longer generated using the default method of hashing over the board's UID at every startup. It is instead generated once using the EdgeLock Secure Enclave and stored into a new NVM dataset as an ELKE blob.
  - Local and peer IRKs are no longer transmitted through HCI in plaintext but as EIRK (Encrypted IRK) blobs, 16 bytes in length, which can be decrypted by the Controller.
- LTK
  - The LTK is no longer stored into NVM as plaintext, but as an ELKE blob. Furthermore, the plaintext of the LTK is never available to the Host/application. Generating the LTK via the ECDH process and generating the Session Key for individual connections is done by the Host via the EdgeLock Secure Enclave and custom vendor HCI messages which are transparent to the application.

At startup, Advanced Secure Mode for the Controller is enabled dynamically by calling:

```
#if (defined(gAppSecureMode_d) && (gAppSecureMode_d > 0U))
    (void) PLATFORM_EnableBleSecureKeyManagement();
#endif
```

This call can be found in BluetoothLEHost_Init, as part of the initialization sequence.

Additional considerations

- The Gap_LoadKeys API will return the IRK in plaintext, having converted it from the ELKE blob which is stored in the NVM. However, it cannot convert the LTK to plaintext - it will thus return the LTK in ELKE blob form.
- As mentioned in the section above, the plaintext LTK is never available. Generating the Session Key for individual connections is done via the EdgeLock Secure Enclave by the Host, using the LTK in ELKE blob form. The Session Key is passed to the Controller via a custom vendor HCI message. Be aware that the content of the HCI_LE_Long_Term_Key_Request_Reply command is not the actual LTK and cannot be used for debugging.
- The Host works with IRKs in ELKE blob form, therefore APIs such as Gap_EnableHostPrivacy and Gap_CreateRandomAddress take ELKE blobs as arguments. The Controller works with IRKs in EIRK blob form, therefore the Gap_EnableControllerPrivacy takes an EIRK blob as argument. This management is done in *ble_conn_manager.c* when Advanced Secure Mode is enabled.

Parent topic:*Application Structure*

Low-Power Management

System considerations

The KW45 has a dual-core architecture and has two separated power domains:

- The main domain for the Cortex M33
- The Radio domain which comprises the Cortex M3 core and the NBU (Narrow Band Unit).

The two power domains can go into or exit independently different low-power modes, namely Wait for instruction (WFI), Deep-sleep mode, Power-down mode, and Deep Power-down mode.

In Wait For Interrupt (WFI) mode, the CPU core is powered ON but is in an idle mode with the clock turned OFF.

In Deep Sleep mode, the fast clock is turned off, and the CPU along with the main power domain are placed into a retention state, with the voltage being scaled down to support state retention only. As no high frequency clock runs in this mode, the voltage applied on the power domain can be reduced to reduce leakage on the hardware logic. This reduces the overall power consumption in the Deep Sleep mode. When waking up from Deep Sleep mode, the core voltage is increased back to nominal voltage, the fast clock (FRO) is turned back on, and the peripheral in this domain can be reused as normal.

In Power-down mode, both the clock, and power are shut off to the CPU and the main peripheral domain. SRAM is retained, but register values are lost. The SDK power manager handles the restore of the processor registers and dependencies such as interrupt controller and similar ones transparently from the application.

In Deep Power-down mode the SRAM is not retained. This is the lowest power mode available. It is exited through the reset sequence.

Parent topic:*Low-Power Management*

When/how to enter low power

To enable low power at application level, the gAppLowpowerEnabled_d define should be set to 1 in app_preinclude.h file.

The system should enter low power when the entire system is idle, and all software layers agree on that. The device enters low power by calling the PWR_EnterLowPower function.

For FreeRTOS applications, the low-power entry point is placed in the FreeRTOS idle task, which has the lowest priority in the system. From that task, the vPortSuppressTicksAndSleep function is called, which at its turn, calls the PWR_EnterLowPower to enter low power.

For the BareMetal examples, the application low power entry point is placed in the main function and is called when there are no messages to be processed by other tasks.

The wake-up sources that can be configured for the application are UART or button. Note that Low-power timer wake-up source and wake-up from the Radio domain are directly enabled from the Connectivity framework.

Each software layer/entity running on the system can prevent it from entering low power by calling *PWR_LowPowerEnterCritical* function. The system stays awake until all software layers that called *PWR_LowPowerEnterCritical* call back *PWR_LowPowerExitCritical* and the system reaches the low-power entry point.

When going to low power, the SDK Power Manager selects the best low-power mode that fits all the constraints.

The default low-power mode for each application is Deep-sleep mode. Users can change the behavior by setting a new low-power constraint for the application.

For example, if the low power constraint set from the application is Deep-sleep mode, and no other constraint is set, the**SDK Power Manager** selects Deep-sleep the next time the device enters low power. However, there might be a case when a WFI constraint is set (*PWR_SetLowPowerModeConstraint (PWR_WFI)*) by another component, such as the SecLib module that operates Hardware encryption. In such cases, the **SDK Power Manager** selects this WFI mode until the constraint is released by the SecLib module (*PWR_ReleaseLowPowerModeConstraint(PWR_WFI)*).

If it is required to change the mode from Deep-sleep to Power-down mode, the deep sleep constraint (*PWR_ReleaseLowPowerModeConstraint(PWR_DeepSleep)*) must be released and the power-down constraint (*PWR_SetLowPowerModeConstraints(PWR_PowerDown)*) must be set. The **SDK Power Manager** selects the Power-down mode when the device enters low power.

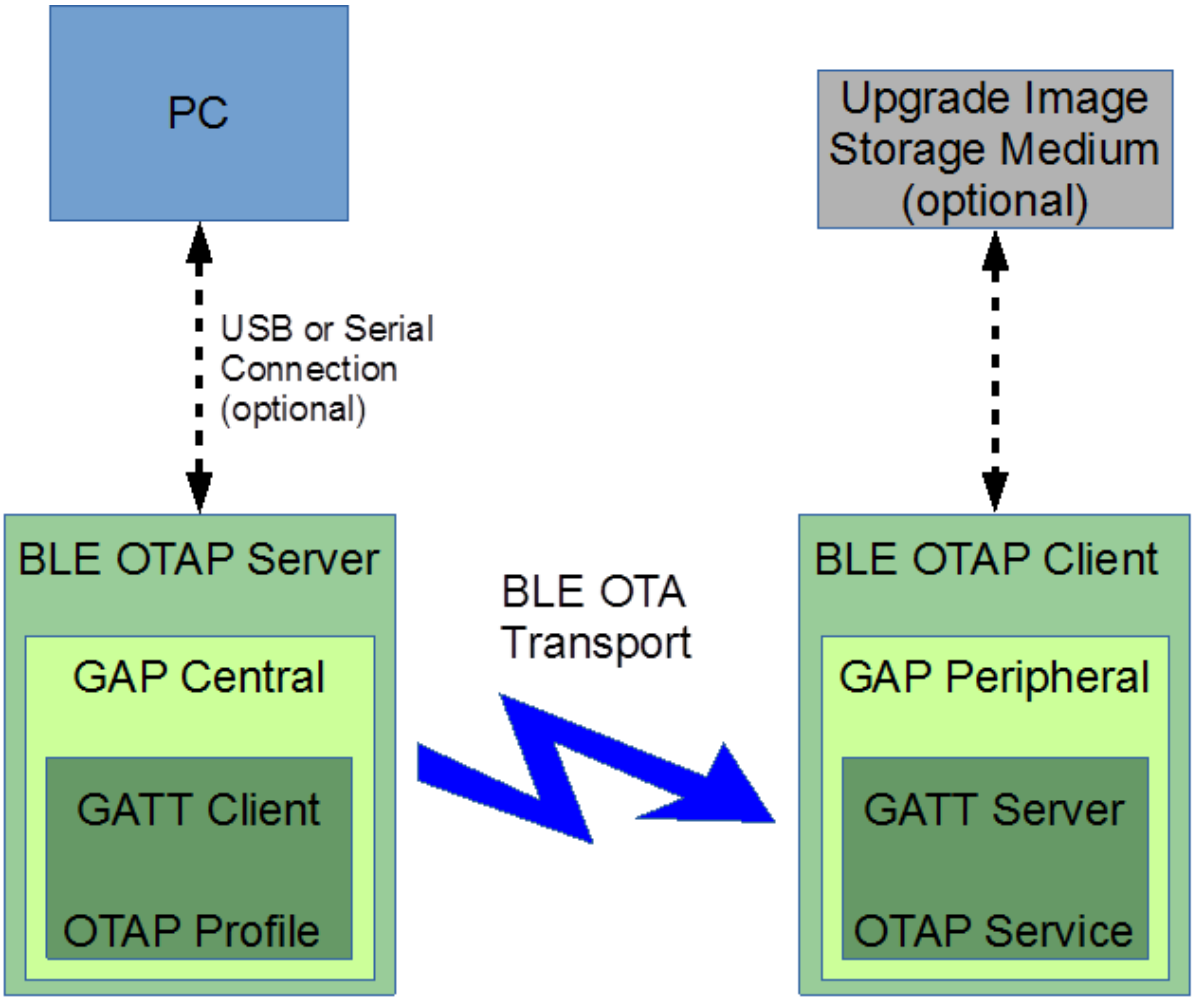
Parent topic:*Low-Power Management*

Over the Air Programming (OTAP)

This chapter contains a detailed description of the Over The Air Programming capabilities of the Bluetooth Low Energy Host Stack enabled by dedicated GATT Service/Profile and of the support modules needed for OTA programming.

The image transfer is done using a dedicated protocol which is designed to run on both the Bluetooth Low Energy transport and serial transport.

The container for the upgrade image is an image file which has a predefined format which is described in detail. The image file format is independent of the protocol but must contain information specific to the image upgrade infrastructure on an OTAP Client device. Detailed information on how to build an image file starting from a generic format executable generated by an embedded cross-compiling toolchain is shown.



The demo applications implement a typical scenario where a new image is sent from a PC via serial interface to a Bluetooth Low Energy OTAP Server and then over the air to an OTAP Client which is the target of the upgrade image. There are 3 applications involved in the OTAP demo: 1 PC application which builds the image file and serves it to the embedded OTAP Server and 2 embedded applications (OTAP Server and OTAP Client). This chapter contains enough information for building Bluetooth Low Energy OTAP applications which implement different image upgrade scenarios specific to other use cases.

General functionality

A Bluetooth Low Energy OTAP system consists of an OTAP Server and an OTAP Client which exchange an image file over the air using the infrastructure provided by Bluetooth Low Energy (GAP, GATT, SM) via a custom GATT Service and GATT Profile. Additionally, a third application may be used to serve an image to the embedded OTAP Server.

The OTAP Server runs on the GATT Client via the Bluetooth Low Energy OTAP Profile and the OTAP Client runs on the GATT Server via the Bluetooth Low Energy OTAP Service. For the moment the OTAP Server runs on the GAP Central and the OTAP Client runs on the GAP Peripheral.

The Figure shows a typical image upgrade scenario.

Parent topic:*Over the Air Programming (OTAP)*

Bluetooth Low Energy OTAP service-profile

The Bluetooth Low Energy OTAP Service is implemented using the GATT Server which runs on the OTAP Client (GAP Peripheral).

The Bluetooth LE OTAP Service does not require any other Bluetooth LE services because it is a custom service it has a 128-bit UUID. The service has 2 custom characteristics which also have 128-bit UUIDs.

The service must be included in the GATT database of the GATT Server as described in *Creating GATT database* of this document.

OTAP service and characteristics

The OTAP Service has a custom 128-bit UUID which is shown below. The UUID is based on a base 128-bit UUID used for Bluetooth LE custom services and characteristics. These are shown in the tables below.

Service	128-bit UUID
Base Bluetooth Low Energy	00000000 -ba5e-f4ee-5ca1-eb1e5e4b1ce0

The OTAP Service custom 128-bit UUID is built using the base UUID by replacing the most significant 4 bytes which are 0 with a value specific to the OTAP Service which is 01FF5550 in hexadecimal format.

Service	UUID (128-bit)
Bluetooth LE OTAP Service	01ff5550 -ba5e-f4ee-5ca1-eb1e5e4b1ce0

The Bluetooth LE OTAP Service Characteristics UUIDs are built the same as the Bluetooth LE OTAP Service UUID starting from the base 128-bit UUID but using other values for the most significant 4 bytes.

Characteristic	UUID (128-bit)	Properties	Descriptors
Bluetooth LE OTAP Control Point	01ff5551 -ba5e-f4ee-5ca1-eb1e5e4b1ce0	Write, Indicate	CCC
Bluetooth LE OTAP Data	01ff5552 -ba5e-f4ee-5ca1-eb1e5e4b1ce0	Write Without Response	-

Both characteristics are implemented as variable length characteristics.

The Bluetooth LE OTAP Control Point Characteristic is used for exchanging OTAP commands between the OTAP Server and the OTAP Client. The OTAP Client sends commands to the OTAP Server using ATT Notifications for this characteristic and the OTAP Server sends commands to the OTAP Client by making ATT Write Requests to this characteristic. Both ATT Writes and ATT Notifications are acknowledged operations via ATT Write Responses and ATT Confirmations.

The Bluetooth LE OTAP Data characteristic is used by the OTAP Server to send parts of the OTAP image file to the OTAP Client when the ATT transfer method is chosen by the application. The ATT Write Commands (GATT Write Without Response operation) is not an acknowledged operation.

The Bluetooth LE OTAP service and characteristics 128-bit UUIDs are defined in the *gatt_uuid128.h* just as shown below.

```
UUID128(uuid_service_otap, 0xE0, 0x1C, 0x4B, 0x5E, 0x1E, 0xEB, 0xA1, 0x5C, 0xEE, 0xF4, 0x5E, 0xBA,␣
↪0x50, 0x55, 0xFF, 0x01)
UUID128(uuid_char_otap_control_point, 0xE0, 0x1C, 0x4B, 0x5E, 0x1E, 0xEB, 0xA1, 0x5C, 0xEE, 0xF4,␣
↪0x5E, 0xBA, 0x51, 0x55, 0xFF, 0x01)
UUID128(uuid_char_otap_data, 0xE0, 0x1C, 0x4B, 0x5E, 0x1E, 0xEB, 0xA1, 0x5C, 0xEE, 0xF4, 0x5E,␣
↪0xBA, 0x52, 0x55, 0xFF, 0x01)
```

The service is included into the GATT database of the device. It is declared in the *gatt_db.h* file as shown below.

```
PRIMARY_SERVICE_UUID128(service_otap, uuid_service_otap)
CHARACTERISTIC_UUID128(char_otap_control_point, uuid_char_otap_control_point,␣
↪(gGattCharPropWrite_c | gGattCharPropIndicate_c))
VALUE_UUID128_VARLEN(value_otap_control_point, uuid_char_otap_control_point,␣
↪(gPermissionFlagWritable_c), 16, 16, 0x00)
CCCD(cccd_otap_control_point)
CHARACTERISTIC_UUID128(char_otap_data, uuid_char_otap_data, (gGattCharPropWriteWithoutRsp_
↪c))
VALUE_UUID128_VARLEN(value_otap_data, uuid_char_otap_data, (gPermissionFlagWritable_c),␣
↪gAttMaxMtu_c - 3, gAttMaxMtu_c - 3, 0x00)
```

The Bluetooth LE OTAP Control Point characteristic should be large enough for the longest command which can be exchanged between the OTAP Server and The OTAP Client.

The Bluetooth LE OTAP Data characteristic should be large enough for the longest data chunk command the OTAP Client expects from the OTAP Server to be sent via ATT. The maximum length

of the OTAP Data Characteristic value is ATT_MTU- 3. 1 byte is used for the ATT OpCode and 2 bytes are used for the Attribute Handle when performing a Write Without Response, the only operation permitted for this characteristic value.

Parent topic: Bluetooth Low Energy OTAP service-profile

OTAP server and OTAP client interactions

The OTAP Server application scans for devices advertising the OTAP Service. When it finds one it connects to that device and notifies it of the available image files or waits for requests regarding available image files. The behavior is specific to each application which needs the OTAP functionality. The Bluetooth LE OTAP Protocol described below details how to do this.

After an OTAP Server (GAP Central, GATT Client) connects to an OTAP Client (GAP Peripheral, GATT Server) it scans the device database and identifies the handles of the OTAP Control Point and OTAP Data characteristics and their descriptors. Then it writes the CCC Descriptor of the OTAP Control point to allow the OTAP Client to send it commands via ATT Indications. It can send commands to the OTAP Client by using ATT Write Commands to the OTAP Control Point characteristic.

After the connection is established, if the OTAP Client wants to use the L2CAP CoC transfer method it must register a L2CAP PSM with the OTAP Server.

The OTAP Client only starts any image information request or image transfer request procedures only after the OTAP Server writes the OTAP Control Point CCCD to ensure there is bidirectional communication between the devices.

Parent topic: Bluetooth Low Energy OTAP service-profile

Parent topic:*Over the Air Programming (OTAP)*

Bluetooth LE OTAP protocol

The protocol consists of a set of commands (messages) which allow the OTAP Client to request or be notified about the available images on an OTAP Server and to request the transfer of parts of images from the OTAP Server.

All commands with the exception of the image data transfer commands are exchanged through the OTAP Control Point characteristic of the OTAP Service. The data transfer commands are sent only from the OTAP Server to the OTAP Client either via the OTAP Data characteristic of the OTAP Service or via a dedicated Credit Based Channel assigned to a L2CAP PSM.

Protocol design considerations

The OTAP Client is a GAP Peripheral device, and therefore has limited resources. This is why the OTAP Protocol was designed in such a way that it is at the discretion of the OTAP Client if, when, how fast and how much of an available upgrade image is transferred from the OTAP Server. The OTAP Client also decides which is the image transfer method based on its capabilities. Two image transfer methods are supported at this moment: the ATT Transfer Method and the L2CAP PSM CoC Transfer Method.

The ATT Transfer Method is supported by all devices which support Bluetooth LE but it has the disadvantage of a small data payload size and a larger Bluetooth LE stack protocols overhead leading to a lower throughput. This disadvantage has been somewhat reduced by the introduction of the Long Frames feature in the Bluetooth LE specification 4.2 Link Layer which allows for a larger ATT_MTU value. The L2CAP PSM CoC Transfer Method is an optional feature available for devices running a Bluetooth stack version 4.1 and later. The protocol overhead is smaller and the data payload is higher leading to a high throughput. The L2CAP PSM Transfer Method is the preferred transfer method and it is available on all Bluetooth LE Devices if the application requires it.

Based on application requirements and device resources and capabilities the OTAP Clients can request blocks of OTAP images divided into chunks. To minimize the protocol overhead and

maximize throughput an OTAP Client makes a data block request specifying the block size and the chunk size and the OTAP Server sends the requested data chunks (which have a sequence number) without waiting for confirmation. The block size, chunk size and number of chunks per block are limited and suitable values must be used based on application needs.

The OTAP Client can stop or restart an image block transfer at any time if the application requires it or a transfer error occurs. The OTAP Server implementation can be almost completely stateless. The OTAP Server does not need to remember what parts of an image have been transferred, this is the job of the OTAP Client which can request any part of an image at any time. This allows it to download parts of the image whenever and how fast its resources allow it. The OTAP Server simply sends image information and image parts on request.

The Bluetooth LE OTAP Protocol is designed to be used not only on Bluetooth LE transport medium but on any transport medium, for example a serial communication interface or another type of wireless interface. This may be useful when transferring an upgrade image from a PC or a mobile device to the OTAP Server to be sent via Bluetooth LE to the OTAP Clients which require it. In the OTAP Demo Applications the embedded OTAP Server relays OTAP commands between an OTAP Client and a PC via a serial interface and using a FSCI type protocol. Effectively the OTAP Client downloads the upgrade image from the PC and not from the OTAP Server. Other transfer methods may be used based on application needs.

Parent topic: Bluetooth LE OTAP protocol

Bluetooth Low Energy OTAP commands

The Bluetooth LE OTAP Commands general format is shown below. A command consists of two parts, a Command ID, and a Command Payload as shown in the table below.

Field Name	CmdId	CmdPayload
Size (Bytes)	1	variable

Commands are sent over the transport medium starting with the Command ID and continuing with the Command Payload.

All multibyte command parameters in the Command Payload are sent in a least significant octet first order (little endian).

A summary of the commands supported by the Bluetooth LE OTAP Protocol is shown in the table below. Each of the commands is then detailed in its own section.

CmdId	Command Name
0x01	New Image Notification
0x02	New Image Info Request
0x03	New Image Info Response
0x04	Image Block Request
0x05	Image Chunk
0x06	Image Transfer Complete
0x07	Error Notification
0x08	Stop Image Transfer

New image notification command

This command can be sent by an OTAP Server to an OTAP Client, usually immediately after the first connection, to notify the OTAP Client of the available images on the OTAP Server.

Table 14: New Image Notification Command Parameters

CmdId	Name	Dir	Parameters	Param Size (Bytes)	Description	Total Size (CmdId + Payload)
0x01	New Image Notification	S->C	ImageId	2	Short image identifier used for transactions between the OTAP Server and OTAP Client. Should be unique for all images on a server.	15
			ImageVersion	8	Image file version. Contains sufficient information to identify the target hardware, stack version and build version.	
			ImageFileSize	4	Image file size in bytes.	

The *ImageId* parameter should not be '0x0000', which is the reserved value for the current running image or 0xFFFF, which is the reserved value for "no image available".

Parent topic: Bluetooth Low Energy OTAP commands

New image info request command

This command can be sent by an OTAP Client to an OTAP Server to inquire about available upgrade images on the OTAP Server.

CmdId	Name	Dir	Parameters	Param Size (Bytes	Description	Total Size (CmdId+Payload)
0x02	New Image Info Request	C->S	CurrImageId	2	Id of the currently running image. Should be 0x0000.	11
0x02	New Image Info Request	C->S	CurrImageV	8	Version of the currently running image. A value of all zeroes signals that the client is looking for all images available on an OTAP Server. A value of all zeroes requests information about all images on the server.	11

- The *CurrImageId* parameter should be set to 0x0000 to signify the current running image.
- The *CurrImageVer* parameter should contain sufficient information about the target device for the OTAP Server to determine if it has an upgrade image available for the requesting OTAP Client.
- A value of all zeroes for the *CurrImageVer* means that an OTAP Client is requesting information about all available images on an OTAP Server and the OTAP Server should send a New Image Info Response for each image.

Parent topic: Bluetooth Low Energy OTAP commands

New image info response command

This command is sent by the OTAP Server to the OTAP Client as a response to a New Image Information Request Command.

CmdId	Name	Dir	Parameters	Param Size (Bytes)	Description	Total Size (CmdId+Payload)
0x03	New Image Info Response	S->C	ImageId	2	Image Id. Value 0xFFFF is reserved as “no image available”	15
0x03	New Image Info Response	S->C	ImageVersion	8	Image file version	15
0x03	New Image Info Response	S->C	4 Image file size.	4	Image file size	15

The *ImageId* parameter with a value of 0xFFFF is reserved for the situation where no upgrade image is available for the requesting device.

Parent topic: Bluetooth Low Energy OTAP commands

Image block request command

This command is sent by the OTAP Client to the OTAP Server to request a part of the upgrade image after it has determined the OTAP Server has an upgrade image available.

When an OTAP Server Receives this command it should stop any image file chunk transfer sequences in progress.

CmdId	Nam	Dir	Parameters	Para Size	Description	Total Size (CmdId+Payload)
0x04	Image Bloc Reques	C->S	StartPositionBlockSizeChunkSizeTransferMethodL2ca	4421	Start position of the image block to be transferred.Requested total block size in bytes.Should be optimized to the Transfer Channel type. The maximum number of chunks per block is 256. Value is inbytes.0x00 - ATT 0x01 – L2CAP PSM Credit based channel0x0004 - ATT Other values – PSM for credit based channels	16

The *ImageId* parameter contains the ID of the upgrade image.

The *StartPosition* parameter specifies the location in the image upgrade file at which the requested block starts.

The *BlockSize* and *ChunkSize* parameters specify the size in bytes of the block to be transferred and the size of the chunks into which a block is separated. The *ChunkSize* value must be chosen in such a way that the total number of chunks can be represented by the *SeqNumber* parameter of the Image Chunk Command. At the moment this parameter is 1 byte in size so there are a maximum of 256 chunks per block. The chunk sequence number goes from 0 to 255 (0x00 to 0xFF). If this condition is not met or the requested block is not entirely into the image file bounds an error is sent to the OTAP Client when the OTAP Server receives this misconfigured Image Block Request Command.

The maximum value of the *ChunkSize* parameter depends on the maximum ATT_MTU and L2CAP_MTU supported by the Bluetooth LE stack version and implementation.

The *TransferMethod* parameter is used to select the transfer method which can be ATT or L2CAP PSM CoC. The *L2capChannelOrPsm* parameter must contain the value 0x0004 for the ATT transfer method and another value representing the chosen PSM for the L2CAP PSM transfer method. The default PSM for the Bluetooth LE OTAP demo applications is 0x004F for both the OTAP Server and the OTAP Client although the specification allows different values at the 2 ends of the L2CAP PSM connection. The PSM must be in the range reserved by the Bluetooth specification which is 0x0040 to 0x007F.

The optimal value of the *ChunkSize* parameter depends on the chosen transfer method and the Link Layer payload size. Ideally it must be chosen in such a way that full packets are sent for every chunk in the block.

The default Link Layer payload is 27 bytes form which we subtract 4 for the L2CAP layer and 3 for the ATT layer (1 for the ATT Cmd Opcode and 2 for the Handle) leaving us with a 20 byte OTAP protocol payload. From these 20 bytes we subtract 1 for the OTAP CmdId and 1 for the chunk sequence number leaving us with an optimum chunk size of 18 for the ATT transfer method – which is the default in the demo applications. For the L2CAP PSM transfer method the chosen default chunk size is 111. This was chosen so as a chunk fits exactly 5 link layer packets. The default L2CAP payload of 23 (27 - 4) multiplied by 5 gives us 115 from which we subtract 2 bytes for the SDU Length (which is only sent in the first packet), 1 byte for the OTAP CmdId and 1 byte for the chunk sequence number which leaves exactly 111 bytes for the actual payload.

If the Link layer supports Long Frames feature then the chunk size should be set according to the negotiated ATT MTU for the ATT transfer method. From the negotiated ATT MTU (*att_mtu*) subtract 3 bytes for the ATT layer (1 for the ATT Cmd Opcode and 2 for the Handle) then subtract 2 bytes for the OTAP protocol (1 for the CmdId and 1 for the chunk sequence number) to determine the optimum chunk size (*optimum_att_chunk_size = att_mtu – 3 – 2)*. For the L2CAP PSM transfer method the chunk size can be set based on the maximum L2CAP SDU size (*max_l2cap_sdu_size*) from which 4 bytes should be subtracted, 2 for the SDU Length and 2 for the OTAP protocol (*optimum_l2cap_chunk_size = max_l2cap_sdu_size – 3 – 2*). In some particular cases reducing the L2CAP chunk size could lead to better performance. If the L2CAP chunk size needs to be reduced it should be reduced so it fits exactly a number of link layer packets. An example of how to compute an optimal reduced L2CAP chunk size is given in the previous paragraph.

Parent topic: Bluetooth Low Energy OTAP commands

Image chunk command

One or more Image Chunk Commands are sent from the OTAP Server to the OTAP Client after an Image Block Request is received by the former. The image chunks are sent via the ATT Write Without Response mechanism if the ATT transfer method is chosen and directly via L2CAP if the L2CAP PSM CoC transfer method is chosen.

CmdId	Name	Dir	Parameters	Parar Size	Description	Total Size (CmdId+Payload)
0x05	Image Chunl	S->C	SeqNumber-Data	1variable	In the range 0 -> BlockSize/ChunkSize - calculated by Server, checked by Client. The command code is present even when ATT is used.Actual data	3 or more

The *SeqNumber* parameter is the chunk sequence number and it has incremental values from 0 to 255 (0x00 to 0x FF) for a maximum of 256 chunks per block.

The *Data* parameter is an array containing the actual image part being transferred starting from the *BlockStartPosition + SeqNumber ChunkSize* position in the image file and containing *ChunkSize* or less bytes depending on the position in the block. Only the last chunk in a block can have less than *ChunkSize*bytes in the Image Chunk Command data payload.

Parent topic: Bluetooth Low Energy OTAP commands

Image transfer complete command

This command is sent by the OTAP Client to the OTAP Server when an image file has been completely transferred and its integrity has been checked.

CmdId	Name	Dir	Parameters	Param Size	Description	Total Size (CmdId+Payload)
0x06	Image Transfer Complete	C->S	ImageIdStatus	21	Image IdStatus of the image transfer. 0x00 - Success	4

The *ImageId* parameter contains the ID of the image file that was transferred.

The *Status* parameter is 0x00 (Success) if image integrity and possibly other checks have been successfully made after the image is transferred and another value if integrity or other kind of errors have occurred.

If the status is 0x00 the OTAP Client can trigger the Bootloader to start flashing the new image. The image flashing should take about 15 seconds for a 160 KB flash memory.

Parent topic: Bluetooth Low Energy OTAP commands

Error notification command

This command can be sent by both the OTAP Server and the OTAP Client when an error of any kind occurs. When an OTAP Server receives this command, it should stop any image file chunk transfer sequences in progress.

CmdId	Name	Dir	Parameters	Param Size (Bytes	Description	Total Size (CmdId+Payload)
0x07	Error Notification	Bidi	CmdIdErrorStatus	11	Id of the command which generated the error.Error Status: Examples: out of image bounds, chunk too small, chunk too large, image verification failure, bad command format, image not available, unknown command	3

The *CmdId* parameter contains the ID of the command which caused the error (if applicable).

The *ErrorStatus* parameter contains the source of the error. All error statuses are defined in the *otapStatus_t* enumerated type in the *otap_interface.h* file.

Parent topic: Bluetooth Low Energy OTAP commands

Stop image transfer command

This command is sent from the OTAP Client to the OTAP Server whenever the former wants to stop the transfer of an image block which is currently in progress, or from OTAP Server to the OTAP Client when the image transfer is stopped from application (Test Tool).

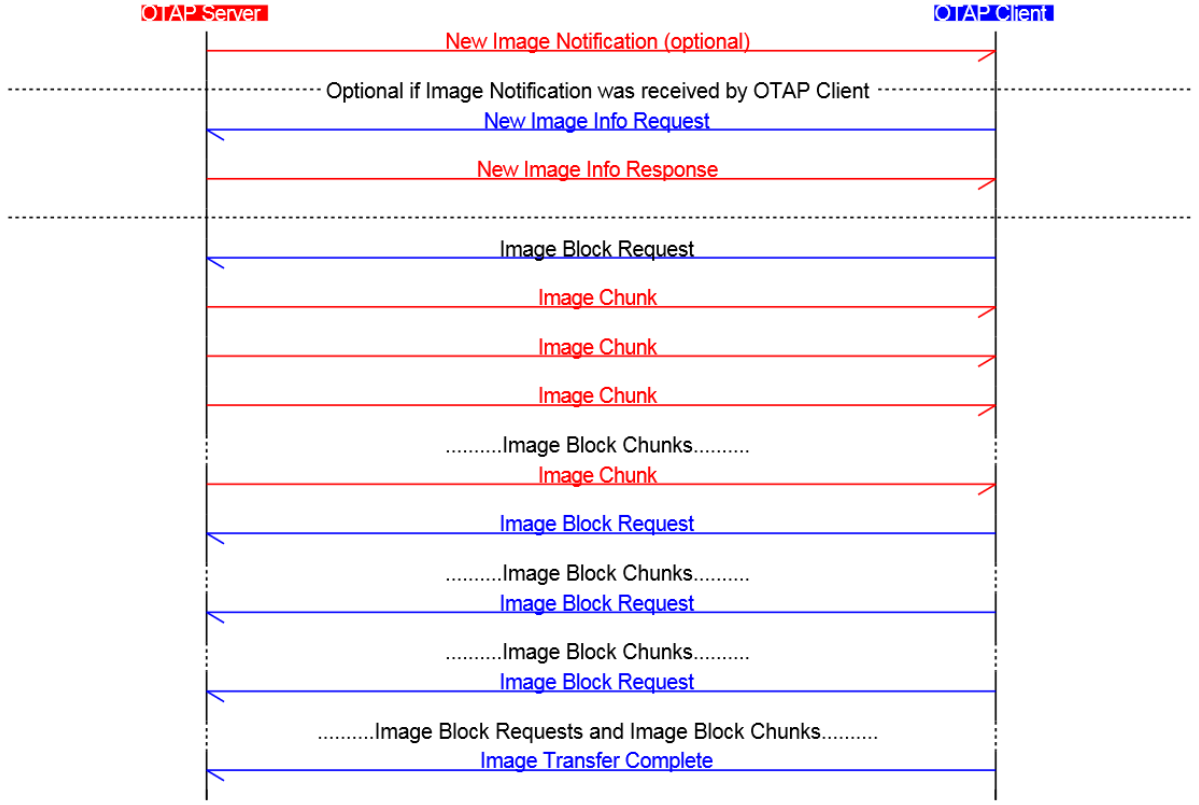
CmdId	Name	Dir	Parameters	Param Size	Description	Total Size (CmdId+Payload)
0x08	Stop Image Transfer	C->S	ImageId	2	Image Id	3

The *ImageId* parameter contains the ID of the image being transferred.

Parent topic: Bluetooth Low Energy OTAP commands

Parent topic: Bluetooth LE OTAP protocol

OTAP client–server interactions



The interactions between the OTAP Server and OTAP Client start immediately after the connection, discovery of the OTAP Service characteristics and writing of the OTAP Control Point CCC Descriptor by the OTAP Server.

The first command sent could be a New Image Notification sent by the OTAP Server to the OTAP Client or a New Image Info Request sent by the OTAP Client. The OTAP Server can respond with a New Image Info response if it has a new image for the device which sent the request (this can be determined from the *ImageVerison* parameter). The best strategy depends on application requirements.

After the OTAP Client has determined that the OTAP Sever has a newer image it can start downloading the image. This is done by Sending Image Block Request commands to retrieve parts of the image file. The OATP Server answers to these requests with one or more Image Chunk Commands via the requested transfer method or with an Error Notification if there are improper parameters in the Image Block Request. The OTAP Client makes as many Image Block Requests as it is necessary to transfer the entire image file.

The OTAP Client decides how often Image Block Request Commands are sent and can even stop a block transfer which is in progress via the Stop Image Transfer Command. The OTAP Client is in complete control of the image download process and can stop it and restart it at any time based on its resources and application requirements.

A typical **Bluetooth LE OTAP Image Transfer** scenario is shown in the message sequence chart Figure.

Parent topic:*Over the Air Programming (OTAP)*

Bluetooth Low Energy OTAP image file format

The Bluetooth LE OTAP Image file has a binary file format. It is composed of a header followed by a number of sub-elements. The header describes general information about the file. There are some predefined sub-elements of a file but an end manufacturer could add manufacturer-specific sub-elements. The header does not have details of the sub-elements. Each element is described by its type.

The general format of an image file is shown in the table below.

Image File Element	Value Field Length (bytes)	Description
Header	Variable	The header contains general information about the image file.
Upgrade Image Sub-element	Variable	This sub-element contains the actual binary executable image, which is copied into the flash memory of the target device. The maximum size of this sub-element depends on the target hardware.
Image File CRC Sub-element	2	This is a 16-bit CCITT type CRC which is calculated over all elements of the image file with the exception of the Image File CRC sub-element itself. This must be the last sub-element in an image file.

Each sub-element in a Bluetooth LE OTAP Image File has a Type-Length-Value (TLV) format. The type identifier provides forward and backward compatibility as new sub-elements are introduced. Existing devices that do not understand newer sub-elements may ignore the data.

The following table shows the general format of a Bluetooth LE Image File sub-element.

Sub-field	Size (Bytes)	Format	Description
Type	2	uint16	Type Identifier – determines the format of the data contained in the value field
Length	4	uint32	Length of the *Value* field of the sub-element.
Value	variable	uint8[]	Data payload

Some sub-element type identifiers are reserved while others are left for manufacturer-specific use. The table below shows the reserved type identifiers and the manufacturer-specific ranges.

Type Identifiers	Description
0x0000	Upgrade Image
0x0001 – 0xefff	Reserved
0xf000 – 0xffff	Manufacturer-Specific Use

The OTAP Demo applications use two of the manufacturer-specific sub-element type identifiers while the rest remain free to use. The two are shown in the table below along with a short description.

Manufacturer-specific Type Identifiers	Sub-element Name	Notes
0xf000	Sector Bitmap	Bitmap that signals the bootloader the sectors of the internal flash, which should be overwritten and which should remain as is.
0xf100	Image File CRC	16-bit CRC that is computed over the image file with the exception of the CRC sub-element itself.

Bluetooth Low Energy OTAP header

The format and fields of the Bluetooth Low Energy OTAP Header are summarized in the table below.

Octets	Data Types	Field Name	Mandatory/Optional
4	Unsigned 32-bit integer	Upgrade File Identifier	M
2	Unsigned 16-bit integer	Header Version	M
2	Unsigned 16-bit integer	Header Length	M
2	Unsigned 16-bit integer	Header Field Control	M
2	Unsigned 16-bit integer	Company Identifier	M
2	Unsigned 16-bit integer	Image ID	M
8	8 byte array	Image Version	M
32	Character string	Header String	M
4	Unsigned 32-bit integer	Total Image File Size	M

The fields are shown in the order they are placed in memory from the first location to the last.

The total size of the header without the optional fields (if defined by the *Header Field Control*) is 58 bytes.

All the fields in the header have a little endian format with the exception of the *Header String* field which is an ASCII character string.

A packed structure type definition for the contents of the Bluetooth LE OTAP Header can be found in the *otap_interface.h* file.

Upgrade file identifier

Fixed value 4 byte field used to identify the file as being a Bluetooth LE OTAP Image File. The predefined value is "**0x0B1EF11E**".

Parent topic: Bluetooth Low Energy OTAP header

Header version

This 2 byte field contains the major and minor version number. The high byte contains the major version and the low byte contains the minor version. The current value is "**0x0100**" with the major version "**01**" and the minor version **"00"**. A change to the minor version means the OTA upgrade file format is still backward compatible, while a change to the major version suggests incompatibility.

Parent topic: Bluetooth Low Energy OTAP header

Header length

Length of all the fields in the header including the ***Upgrade File Identifier*** field, ***Header Length*** field and all the optional fields. The value insulates existing software against new fields that

may be added to the header. If new header fields added are not compatible with current running software, the implementations should process all fields they understand and then skip over any remaining bytes in the header to process the image or CRC sub-element. The value of the ***Header Length*** field depends on the value of the Header Field Control field, which dictates which optional header fields are included.

Parent topic: Bluetooth Low Energy OTAP header

Header field control

This is a 2-byte bit mask that specifies the optional fields present in the OTAP Header.

In case no optional fields are defined, this whole field is reserved and should be set to "**0x0000**".

Parent topic: Bluetooth Low Energy OTAP header

Company identifier

This is the company identifier assigned by the Bluetooth SIG. The Company Identifier used for the OTAP demo applications is "**0x01FF**".

Parent topic: Bluetooth Low Energy OTAP header

Image ID

This is a unique short identifier for the image file. It is used to request parts of an image file. This number should be unique for all images available on a Bluetooth LE OTAP Server.

- The value 0x0000 is reserved for the current running image.
- The value 0xFFFF is reserved as a "no image available" code for New Image Info Response commands.

This field value must be used in the *ImageID* field in the *New Image Notification* and *New Image Info Response* commands.

Parent topic: Bluetooth Low Energy OTAP header

Image version

This is the full identifier of the image file. It should allow a Bluetooth LE OTAP Client to identify the target hardware, stack version, image file build version, and other parameters if necessary. The recommended format of this field (which is used by the OTAP Demo applications) is shown below but an end device manufacturer could choose different format. The subfields are shown in the order they are placed in memory from the first location to the last. Each subfield has a little-endian format, if applicable.

Subfield	Size (bytes)	Format	Description
Build Version	3	uint8[]	Image build version.
Stack Version	1	uint8	0x41 for example for Bluetooth Low Energy Stack version 4.1.
Hardware ID	3	uint8[]	Unique hardware identifier.
End Manufacturer Id	1	uint8	ID of the hardware–specific to the end manufacturer

This field value must be used in the *ImageVersion* field in the New Image Notification and New Image Info Response commands.

Parent topic: Bluetooth Low Energy OTAP header

Header string

This is a manufacturer-specific string that may be used to store other necessary information as seen fit by each manufacturer. The idea is to have a human readable string that can prove helpful during the development cycle. The string is defined to occupy 32 bytes of space in the OTAP Header. The default string used for the Bluetooth LE OTAP demo application is "BLE OTAP Demo Image File".

Parent topic: Bluetooth Low Energy OTAP header

Total image file size

The value represents the total image size in bytes. This is the total of data in bytes that is transferred over-the-air from the server to the client. In most cases, the total image size of an OTAP upgrade image file is the sum of the sizes of the OTAP Header and all the other sub-elements on the file. If the image contains any integrity and/or source identity verification fields then the Total Image File Size also includes the sizes of these fields.

Parent topic:*Over the Air Programming (OTAP)*

Building Bluetooth Low Energy OTAP image file from SREC file

A SREC (Motorola S-record) file is an ASCII format file which contains binary information. Common file extensions are: .srec, .s19, .s28, .s37 and others. Most modern compiler toolchains can generate an SREC format executable.

The steps described in this section enable the creation of a SREC file for your embedded application in IAR Embedded Workbench.

For this, open the target properties and go to the **Output Converter** tab. Activate the **Generate additional output** checkbox and choose the **Motorola** option from the **Output format** drop down menu. From the same pane you can also override the name of the output file. A screenshot of the described configuration is shown in the Figure below.

The format of the SREC file is shown in table below. It contains lines of text called records which have a specific format. An example of the contents of a SREC file is shown below.

```
S02000006F7461705F636C69656E745F6174745F4672656552544F532E73726563A1
S1130000F83F0020EB050000750600075060000AF
S1130010750600007506000075060000750600F0
S1130020750600007506000075060000750600E0
S1130030750600007506000075060000750600D0
S1130040000000000000000000000000000000AC
S113005000000000000000000000000000000009C
.....
S2140117900121380004F05FF8002866D12A003100E4
S2140117A06846008804F022F8A689002E16D0002884
S2140117B014D12569278801A868A11022F7F782FCB1
S2140117C06B4601AA0121380004F045F800284CD1E7
S2140117D02A0031006846008804F008F8A68A002E20
```

All records start with the ASCII letter ‘S’ followed by an ASCII digit from ‘0’ to ‘9’. These two characters from the record type identify the format of the data field of the record.

The next 2 ASCII characters are 2 hex digits that indicate the number of bytes (hex digit pairs) which follow the rest of the record (address, data, and checksum).

The address that follows next can have 4, 6, or 8 ASCII hex digits, depending on the record type.

The data field is placed after the address and it contains 2 * n ASCII hex digits for ‘n’ bytes of actual data.

The last element of the S record is the checksum, which comprises 2 ASCII hex digits. The check-

sum is computed by adding all the bytes of the byte count, address, and data fields. Then the ones complement of the least significant octet of the sum is computed to determine the checksum.

Field	Record Type	Count	Address	Data	Check-sum	Line Ter-minator
Format	“Sn”, n=0..9	ASCI-Ihex digits	ASCI-Ihex digits	ASCIIhex digits	ASCI-Ihex digits	“\r\n”
Length (charac-ters)	2	2	4,6,8	*Count –*len*(Address) – *len(*Checksum)*	2	2

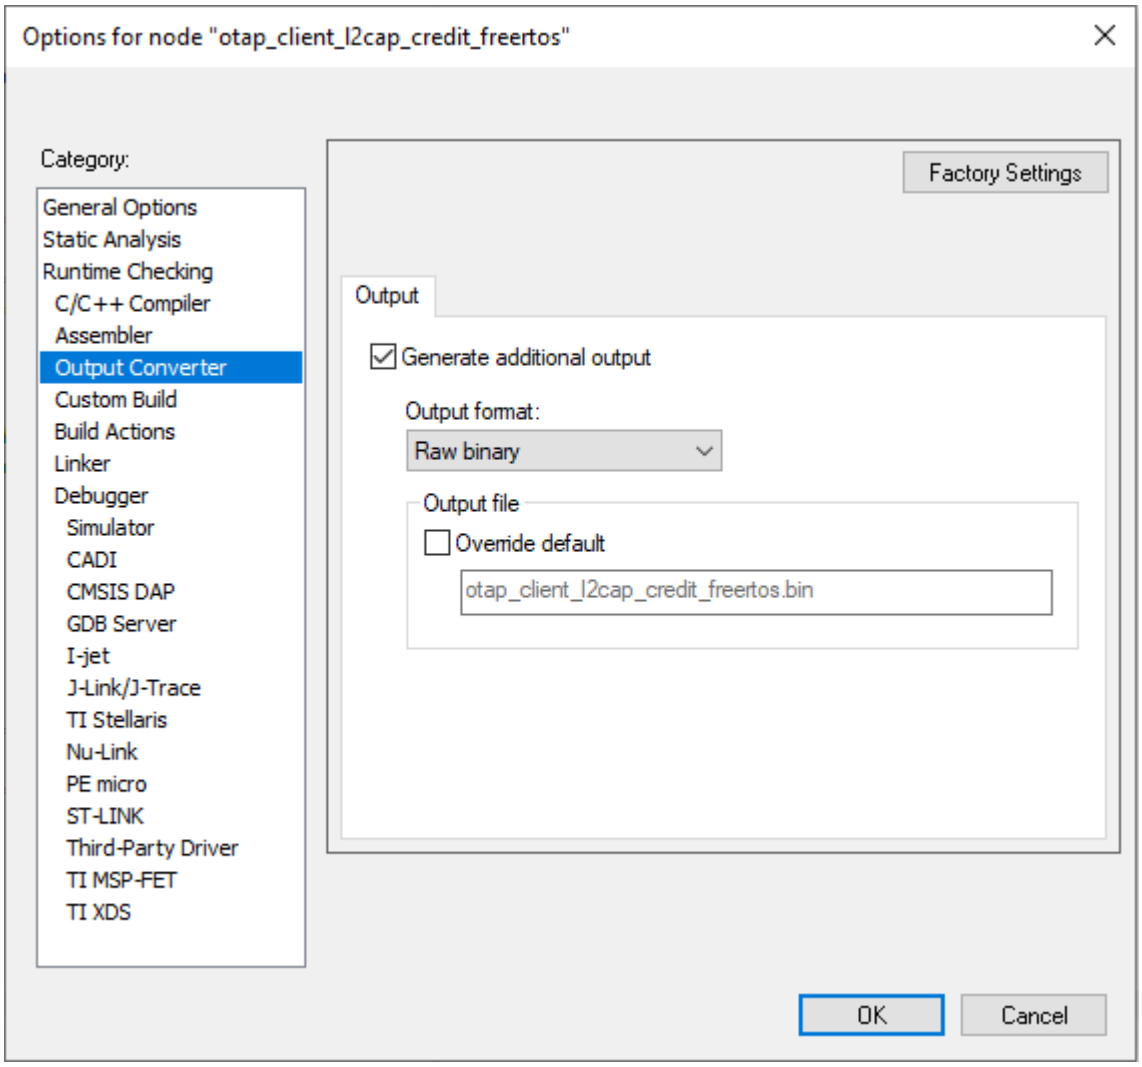
More details about the SREC file format can be found at this location: en.wikipedia.org/wiki/SREC_(file_format).

We are only interested in records that contain actual data. These are S1, S2, and S3 records. The other types of records can be ignored.

The S1, S2, and S3 records are used to build the Upgrade Image Sub-element of the image file simply by placing the record data at the location specified by the record address in the *Value* field of the Sub-element. It is recommended to fill all gaps in S record addresses with 0xFF.

To build an OTAP Image File from a SREC file, follow the procedure described below:

- Generate the SREC file by correctly configuring your toolchain to do so.
- Create the image file header.
  - Set the Image ID field of the header to be unique on the OTAP Server.
  - Leave the Total Image File Size Field blank for the moment.
- Create the Upgrade Image Sub-element
  - Read the S1, S2, and S3 records from the SREC file and place the binary record data to the record addresses in the *Value* filed of the sub-element. Fill all address gaps in the S records with 0xFF.
  - Fill in the *Length* field of the sub-element with the length of the written *Value* field.
- Create the Sector Bitmap Sub-element
  - A default working setting would be all byes 0xFF for the *Value* field of this sub-element.
- Create the Image File CRC Sub-element
  - Compute the total image file size as the length of the header + the length of all 3 sub-elements and fill in the appropriate filed in the header with this value.
  - Compute and write the *Value*field of this sub-element using the header and all sub-elements except this one.
  - The *OTA_CrcCompute()* function in the *OtaSupport.c* file can be used to incrementally compute the CRC.



If the Image ID is not available when the image file is created, then the CRC cannot be computed. It can be computed later after the Image ID is established and written in the appropriate field in the header.

Parent topic:*Over the Air Programming (OTAP)*

Building Bluetooth Low Energy OTAP image file from BIN file

A BIN file is an binary file which contains an executable image. The most common extension for this type of file is .bin. Most modern compiler toolchains can output a BIN format executable.

To enable the creation of a BIN file for your embedded application in IAR Embedded Workbench open the target properties and go to the *Output Converter* tab. Activate the *"Generate additional output"* checkbox and choose the *binary* option from the *"Output format"* drop down menu. From the same pane you can also override the name of the output file. The Figure shows a screenshot of the described configuration.

The format of the BIN file is very simple. It contains the executable image in binary format as is, starting from address 0 and up to the highest address. This type of file does not have any explicit address information.

To build an OTAP Image File from a BIN file, follow the procedure below:

- Generate the BIN file by correctly configuring your toolchain to do so.
- Create the image file header
  - Set the Image ID field of the header to be unique on the OTAP Server.
  - Leave the Total Image File Size field blank for the moment.
- Create the Upgrade Image Sub-element
  - Copy the entire contents of the BIN file as is into the *Value* filed of the sub-element.
  - Fill in the *Length* field of the sub-element with the length of the written *Value* filed.
- Create the Sector Bitmap Sub-element
  - A default working setting would be all bytes 0xFF for the *Value* field of this sub-element.

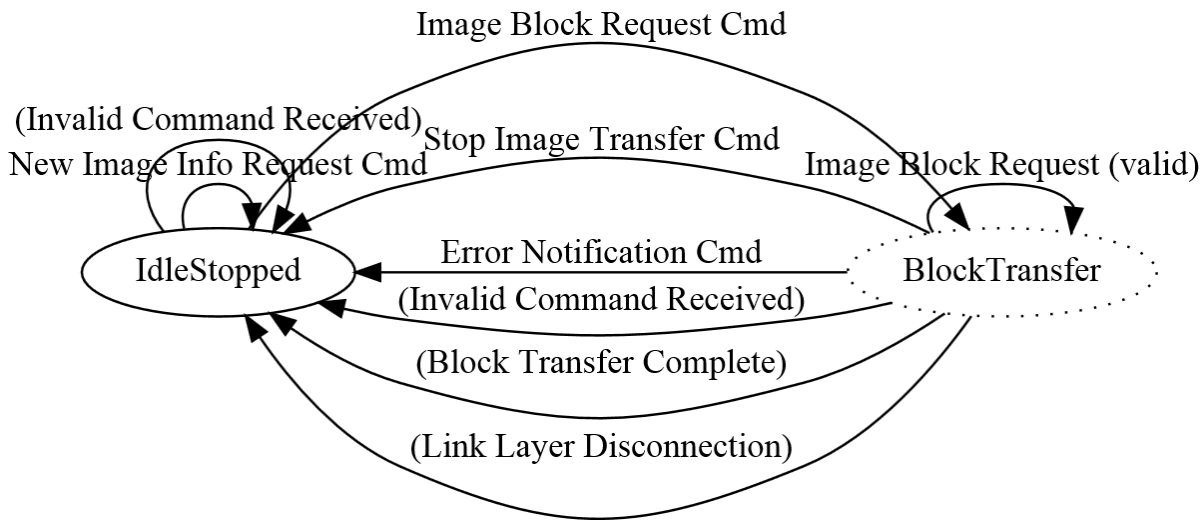
- Create the Image File CRC Sub-element
  - Compute the total image file size as the length of the header + the length of all 3 sub-elements and fill in the appropriate filed in the header with this value.
  - Compute and write the *Value*field of this sub-element using the header and all sub-elements except this one.
  - The *OTA_CrcCompute()* function in the *OtaSupport.c* file can be used to incrementally compute the CRC.

If the Image ID is not available when the image file is created, then the CRC cannot be computed. It can be computed later after the Image ID is established and written in the appropriate field in the header.

Parent topic:*Over the Air Programming (OTAP)*

Bluetooth Low Energy OTAP application integration

The Bluetooth Low Energy OTAP demo applications are standalone applications that only run the OTAP Server and the OTAP Client. In practice, however the OTAP Server and OTAP Client are used alongside with other functions. The OTAP functionality is used as a tool along with the main application on a device.



This section contains some guidelines on how to integrate OTAP functionality into other Bluetooth Low Energy applications.

OTAP server

Before any OTAP transactions can be done the application which acts as an OTAP Server must connect to a peer device and perform ATT service and characteristic discovery. Once the handles of the OTAP Service, OTAP Control Point and OTAP Data characteristics and their descriptors are found then OTAP communication can begin.

A good starting point for OTAP transactions for both the OTAP Server and The OTAP client is the moment the Server writes the OTAP Control Point CCCD to receive ATT Indications from the OTAP Client. At that point the Server can send a New Image Notification to the Client if it finds out what kind of device the client is through other means than the OTAP server. How this can be done is entirely application-specific. If the OTAP Server does not know exactly what kind of device is the OTAP Client it can wait for the Client to send a New Image Info Request. Again, the best behavior depends on application requirements.

Once OTAP communication begins then the OTAP Server just has to wait for commands from the OTAP Client and answer them. This behavior is almost completely stateless. An example state diagram for the OTAP Server application is shown in Figure.

The OTAP Server waits in an idle state until a valid Image Block Request command is received and then moves to a pseudo-state and starts sending the requested block. The transfer can be interrupted by some commands (Error Notification, Stop Image Transfer, and so on) or other events (disconnection, user interruption, and so on).

The *otap_interface.h* file contains infrastructure for sending and receiving OTAP Commands and parsing OTAP image files. Packed structure types are defined for all OTAP commands and type enumerations are defined for command parameter values and some configuration values like the data payloads for the different transfer methods.

To receive ATT Indications and ATT Write Confirmations from the OTAP Client the OTAP Server application registers a set of callbacks in the stack. This is done in the *BluetoothLEHost_Initialized* function.

```
App_RegisterGattClientProcedureCallback (BleApp_GattClientCallback);
App_RegisterGattClientIndicationCallback (BleApp_GattIndicationCallback);
```

This *BleApp_GattIndicationCallback()* function is called when any attribute is indicated so the handle of the indicated attribute must be checked against a list of expected handles. In our case, we are looking for the OTAP Control Point handle that was obtained during the discovery procedure.

The *BleApp_GattIndicationCallback()* function from the demo calls an application-specific function called *BleApp_AttributeIndicated()* in which the OTAP Commands are handled.

```
static void BleApp_AttributeIndicated
(
    deviceId_t     deviceId,
    uint16_t       handle,
    uint8_t*       pValue,
    uint16_t       length
)
{
    if (handle == mPeerInformation.customInfo.otapServerConfig.hControlPoint)
    {
       otapCommandVars.pValueTemp = pValue;
        otapCommand_t*  pOtaCmd = otapCommandVars.otapCommandTemp;
        /* ... Missing code here ... */
        /* If the OTAP Server does not have internal storage then all commands must be forwarded
          *  via the serial interface. */
            FsciBleOtap_SendPkt (&(pOtaCmd->cmdId),
                        (uint8_t*)(&(pOtaCmd->cmd)),
                        length - gOtap_CmdIdFieldSize_c);
    }
    elseif (handle == otherHandle)
    {
        /* Handle other attribute indications here */
        /* ... Missing code here ... */
    }
    else
    {
        /*! A GATT Client is trying to GATT Indicate an unknown attribute value.
         * This should not happen. Disconnect the link. */
        Gap_Disconnect (deviceId);
    }
}
```

OTAP Server demo does not have internal storage, so all commands are forwarded via the serial interface.

To send OTAP Commands to the OTAP Client the application running the OTAP Server calls the *OtapServer_SendCommandToOtapClient()* function, which performs an ATT Write operation on the OTAP Control Point attribute.

```
static void OtapServer_SendCommandToOtapClient
       (deviceId_t  otapClientDevId,
        void*       pCommand,
        uint16_t    cmdLength)
{
   /* GATT Characteristic to be written - OTAP Client Control Point */
   gattCharacteristic_t    otapCtrlPointChar;
   bleResult_t             bleResult;

   /* Only the value handle element of this structure is relevant for this operation. */
   otapCtrlPointChar.value.handle = mPeerInformation.customInfo.otapServerConfig.hControlPoint;
   otapCtrlPointChar.value.valueLength = 0;
   otapCtrlPointChar.cNumDescriptors = 0;
   otapCtrlPointChar.aDescriptors = NULL;

   bleResult = GattClient_SimpleCharacteristicWrite (mPeerInformation.deviceId,
                                          &otapCtrlPointChar,
                                          cmdLength,
                                          pCommand);

   if (gBleSuccess_c == bleResult)
   {
      otapServerData.lastCmdSentToOtapClient = (otapCmdIdt_t)(((otapCommand_t*)pCommand)->
↪cmdId);
   }
   else
   {
      /*! A Bluetooth Low Energy error has occurred - Disconnect */
      (void)Gap_Disconnect (otapClientDevId);
   }
}
```

The ATT Confirmation for the ATT Write is received in the *BleApp_GattClientCallback()* set up earlier which receives a GATT procedure success message for a *gGattProcWriteCharacteristicValue_c* procedure type.

```
static void BleApp_GattClientCallback(
   deviceId_t              serverDeviceId,
   gattProcedureType_t     procedureType,
   gattProcedureResult_t   procedureResult,
   bleResult_t             error
)
{
  union
   {
      uint8_t                 errorTemp;
      attErrorCode_t          attErrorCodeTemp;
   }attErrorCodeVars;

   if (procedureResult == gGattProcError_c)
   {
      attErrorCodeVars.errorTemp = (uint8_t)error & 0xFFU;
      attErrorCode_t attError = attErrorCodeVars.attErrorCodeTemp;
      if (attError == gAttErrCodeInsufficientEncryption_c     ||
          attError == gAttErrCodeInsufficientAuthorization_c  ||
          attError == gAttErrCodeInsufficientAuthentication_c)
      {
   #if gAppUsePairing_d
         /* Start Pairing Procedure */
         (void)Gap_Pair (serverDeviceId, &gPairingParameters);
   #endif
```

(continues on next page)

(continued from previous page)

```
        }

        BleApp_StateMachineHandler (serverDeviceId, mAppEvt_GattProcError_c);
    }
    else if (procedureResult == gGattProcSuccess_c)
    {
        switch(procedureType)
        {
            /* ... Missing code here... */
            case gGattProcWriteCharacteristicValue_c:
            {
                BleApp_HandleValueWriteConfirmations (serverDeviceId);
            }
            break;

            default:
                ; /* For MISRA compliance */
           break;
        }

        BleApp_StateMachineHandler(serverDeviceId, mAppEvt_GattProcComplete_c);
    }
    else
    {
        ; /* For MISRA compliance */
    }
}
```

The *BleApp_HandleValueWriteConfirmations()* function deals with ATT Write Confirmations based on the requirements of the application.

There are two possible transfer methods for Image Chunks, the ATT transfer method and the L2CAP transfer method. The OTAP server is prepared to handle both, as requested by the OTAP Client.

To be able to use the L2CAP transfer method, the OTAP Server application must register a L2CAP LE PSM and 2 callbacks: a data callback and a control callback. This is done by using the *BluetoothLEHost_Initialized()* function.

```
/* Register OTAP L2CAP PSM */
  L2ca_RegisterLePsm (gOtap_L2capLePsm_c,
                      gOtapCmdImageChunkCocMaxLength_c); /*!< The negotiated MTU must be higher than␣
↪the biggest data chunk that is sent fragmented */
...
  App_RegisterLeCbCallbacks(BleApp_L2capPsmDataCallback, BleApp_L2capPsmControlCallback);
```

The data callback *BleApp_L2capPsmDataCallback()* is not used by the OTAP Server.

The control callback is used to handle L2CAP LE PSM connection requests from the OTAP Client and other events: PSM disconnections, No peer credits, and so on. The OTAP Client must initiate the L2CAP PSM connection if it wants to use the L2CAP transfer method.

```
static void BleApp_L2capPsmControlCallback(l2capControlMessage_t* pMessage)
{
    switch (pMessage->messageType)
    {
        case gL2ca_LePsmConnectRequest_c:
        {
            l2caLeCbConnectionRequest_t *pConnReq = &pMessage->messageData.connectionRequest;

            /* Respond to the peer L2CAP CB Connection request - send a connection response. */
            (void)L2ca_ConnectLePsm (gOtap_L2capLePsm_c,
```

(continues on next page)

(continued from previous page)

```
                        pConnReq->deviceId,
                        mAppLeCbInitialCredits_c);
            break;
        }
        case gL2ca_LePsmConnectionComplete_c:
        {
            l2caLeCbConnectionComplete_t *pConnComplete = &pMessage->messageData.connectionComplete;

            if (pConnComplete->result == gSuccessful_c)
            {
                /* Set the application L2CAP PSM Connection flag to TRUE because there is no gL2ca_
↪LePsmConnectionComplete_c
                 * event on the responder of the PSM connection. */
                otapServerData.l2capPsmConnected = TRUE;
                otapServerData.l2capPsmChannelId = pConnComplete->cId;

                if (pConnComplete->peerMtu > gOtap_l2capCmdMtuDataChunkOverhead_c)
                {
                    otapServerData.negotiatedMaxL2CapChunkSize = pConnComplete->peerMtu - gOtap_
↪l2capCmdMtuDataChunkOverhead_c;
                }
            }
            break;
        }
        case gL2ca_LePsmDisconnectNotification_c:
        {
            l2caLeCbDisconnection_t *pCbDisconnect = &pMessage->messageData.disconnection;

            /* Call App State Machine */
            BleApp_StateMachineHandler (pCbDisconnect->deviceId, mAppEvt_CbDisconnected_c);

            otapServerData.l2capPsmConnected = FALSE;
            break;
        }
        case gL2ca_NoPeerCredits_c:
        {
            l2caLeCbNoPeerCredits_t *pCbNoPeerCredits = &pMessage->messageData.noPeerCredits;
            (void)L2ca_SendLeCredit (pCbNoPeerCredits->deviceId,
                        otapServerData.l2capPsmChannelId,
                        mAppLeCbInitialCredits_c);
            break;
        }
        case gL2ca_Error_c:
        {
            /* Handle error */
            break;
        }
        default:
            ; /* For MISRA compliance */
            break;
    }
}
```

The ATT transfer method is supported by default but the L2CAP transfer method only works if the OTAP Client opens an L2CAP PSM credit-oriented channel.

To send data chunks to the OTAP Client the OTAP Server application calls the *OtapServer_SendCImgChunkToOtapClient()* function which delivers the chunk via the selected transfer method. For the ATT transfer method the chunk is sent via the *GattClient_CharacteristicWriteWithoutResponse()* function and for the L2CAP transfer method the chunk is sent via the *L2ca_SendLeCbData()* function.

```
static void OtapServer_SendCImgChunkToOtapClient(deviceId_t otapClientDevId,
                                                 void      pChunk,
                                                 uint16_t  chunkCmdLength)
{
    bleResult_t bleResult = gBleSuccess_c;
    if (otapServerData.transferMethod == gOtapTransferMethodAtt_c)
    {
        /* GATT Characteristic to be written without response - OTAP Client Data */
        gattCharacteristic_t otapDataChar;
        /* Only the value handle element of this structure is relevant for this operation. */
        otapDataChar.value.handle = mPeerInformation.customInfo.otapServerConfig.hData;
        bleResult = GattClient_CharacteristicWriteWithoutResponse
                                            (mPeerInformation.deviceId,
                                             &otapDataChar,
                                             chunkCmdLength,
                                             pChunk);
    }
    else if (otapServerData.transferMethod == gOtapTransferMethodL2capCoC_c)
    {
        bleResult = L2ca_SendLeCbData (mPeerInformation.deviceId,
                                       otapServerData.l2capPsmChannelId,
                                       pChunk,
                                       chunkCmdLength);
    }
    if (gBleSuccess_c != bleResult)
    {
        /*! A Bluetooth Low Energy error has occurred - Disconnect */
        Gap_Disconnect (otapClientDevId);
    }
}
```

The OTAP Server demo application relays all commands received from the OTAP Client to a PC through the FSCI type protocol running over a serial interface. It also directly relays all responses from the PC back to the OTAP Client.

Other implementations can bring the image to an external memory through other means of communication and directly respond to the OTAP Client requests.

Parent topic: Bluetooth Low Energy OTAP application integration

OTAP client

An application running an OTAP Client must wait for an OTAP Server to connect and perform service and characteristic discovery before performing any OTAP-related operations. OTAP transactions can begin only after the OTAP Server writes the OTAP Control point CCC Descriptor to receive ATT Notifications. After this is done, bidirectional communication is established between the OTAP Server and Client and OTAP transactions can begin.

The OTAP Client can advertise the OTAP Service via the demo application. Optionally, the OTAP Server may already know the advertising device has an OTAP Service based on application-specific means. In both situations, the OTAP Server must discover the handles of the OTAP Service and its characteristics.

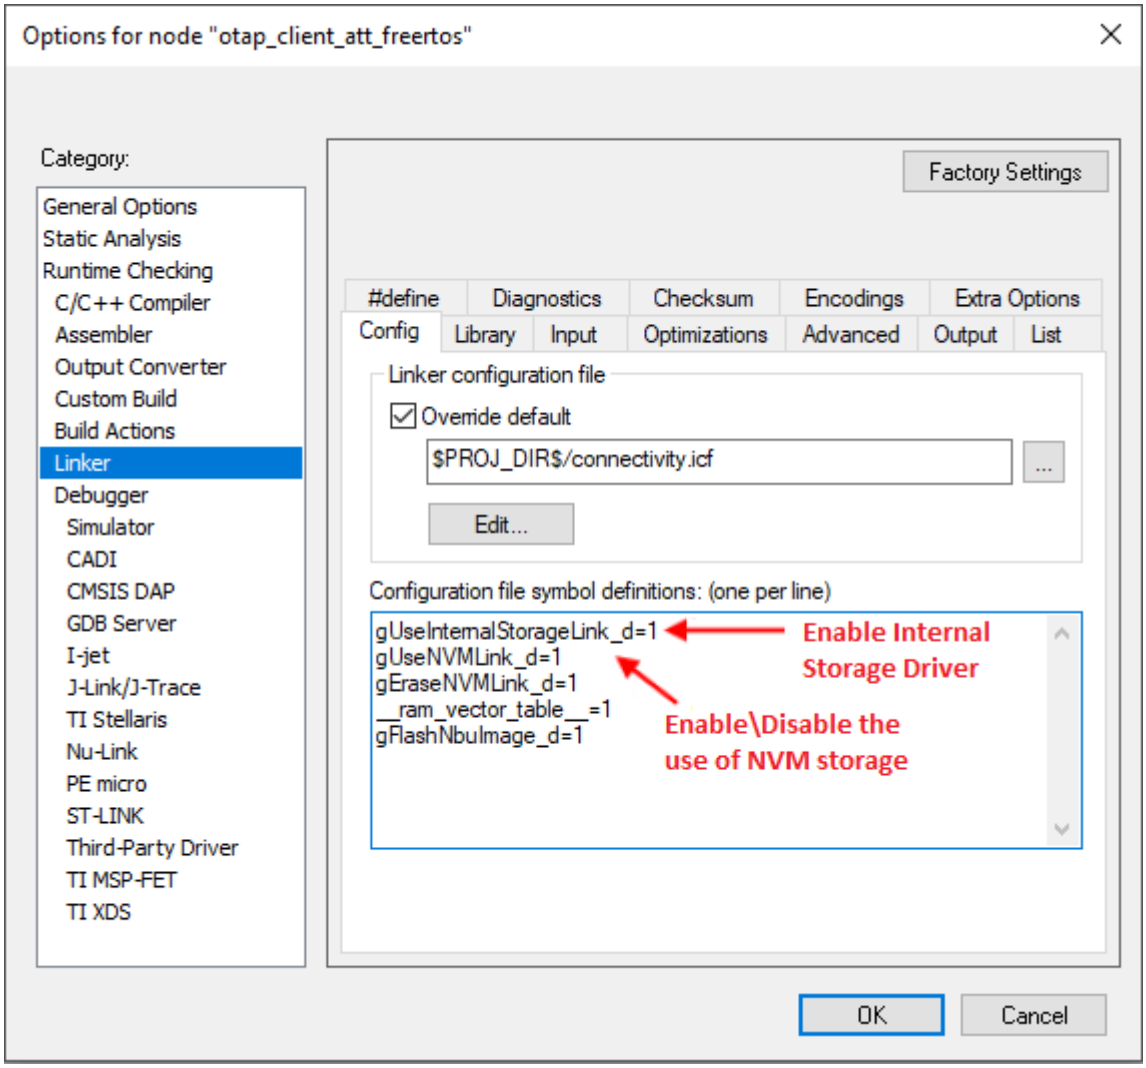
In addition to the OTAP Service instantiated in the GATT Database, the OTAP Client needs to have some storage capabilities for the downloaded image file.

How to put the OTAP Service in the GATT Database is described in The OTAP Service and Characteristics.

The upgrade image storage capabilities in the demo OTAP Client applications are handled by the *OtaSupport* module from the Framework, which contains support modules and drivers. The *OtaSupport* module has support for both internal storage (a part of the internal flash memory is reserved for storing the upgrade image) and external storage (a SPI flash memory chip).

The demo applications use internal storage by default. The internal storage is viable only if there is enough space in the internal flash for the upgrade image – the flash in this case should be at least twice the size of the largest application. The *OtaSupport* module also needs the *Eeprom* module from the Framework to work correctly.

The OtaSupport module also includes functionality for configuring the OTACFG IFR sections after the image is received in order to enable the ROM bootloader to perform the actual image update.



To use the *OtaSupport* module several configuration options must be set up in both the source files and the linker options of the toolchain.

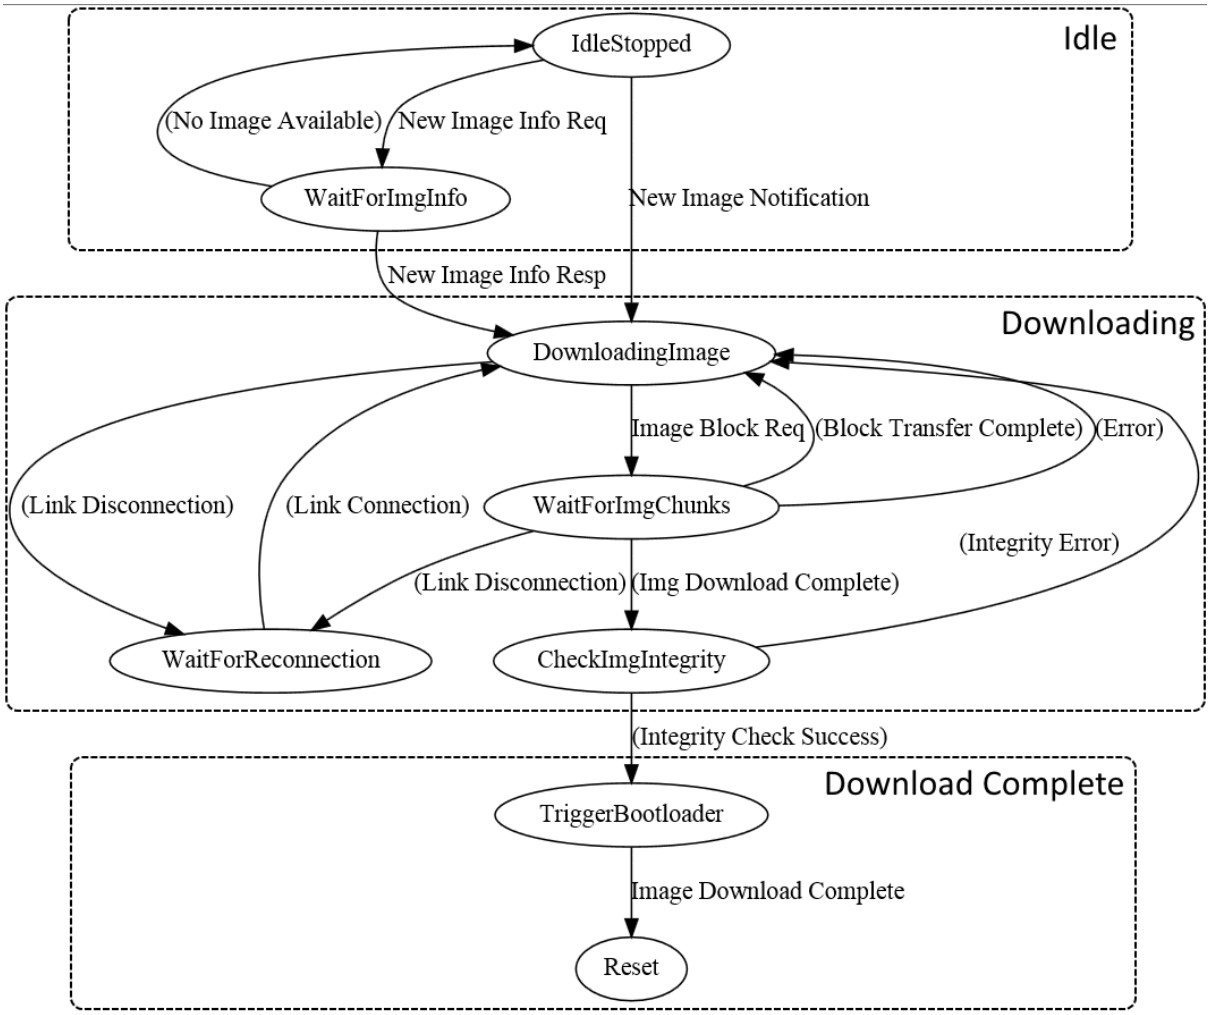
To use internal storage, set up the gUseInternalStorageLink_d=1 symbol in the linker configuration window (**Linker->Config tab** in the IAR project properties) and set the gAppOtaExternalStorage_c value to (0) in the app_preinclude.hfile:

```
/*! Define as 1 to place OTA storage in external flash */
 #define gAppOtaExternalStorage_c (0)
```

The OTAP demo applications for the IAR EW IDE have some settings in the Linker options tab which must be configured to use OtaSupport and the OTAP Bootloader. In the **Project Target Options->Linker->Config** tab, 3 symbols must be correctly defined. To use NVM storage, thegUseNVMLink_d symbol must be set to 1. The gUseInternalStorageLink_d symbol must be set to 0 when OTAP external storage is used and to 1when the internal storage is used. The gEraseNVMLink_d must be set to 0.

An example linker configuration window for IAR is shown below.

Note: The gEraseNVMLink_d=1 IAR linker flag places some dummy bytes into the NVM region to invalidate the data and force the application to erase the entire NVM region. When generating an image for the OTA upgrade, this flag must be set to 0. This results in a smaller image size being transferred and lower power consumption. If the NVM region must be erased after the upgrade process, the "Preserve NVM" checkbox (from the Over The Air programming tool) should be unchecked.



Once the application starts and bidirectional OTAP communication is established via the OTAP Service, then the OTAP Client must determine if the connected OTAP Server has a newer image than the one currently present on the device. This can be done in two ways:

- The OTAP Server knows by some application-specific means that it has a newer image and sends a New Image Notification to the OTAP Client or
- The OTAP Client sends a New Image Info Request to the OTAP Server and waits for a response. This example application uses the second method.

The New Image Info Request contains enough information about the currently running image to allow the OTAP Server to determine if it has a newer image for the requesting device. The New Image Info Response contains enough information for the OTAP Client to determine if the "dead-vertised" image is newer and it wants to download it. The best method is entirely dependent on application requirements.

An example function that checks if an *ImageVerison* field from a New Image Notification or a New Image Info Response corresponds to a newer image (based on the suggested format of this field) is provided in the OTAP Client demo applications. The function is called *OtapClient_IsRemoteImageNewer()*.

The OTAP Client application is a little more complicated than the OTAP Server application because more state information needs to be handled (current image position, current chunk sequence number, image file parsing information, and so on). An example state diagram for the OTAP Client is shown below. The Figure briefly lists the steps of the image download process. Note that some of the states may not be explicitly present in the demo applications.

After the OTAP Client determines that the peer OTAP Server has a suitable upgrade image available, it can start the download process. This is done by sending multiple Image Block Request messages and waiting for the Image Chunks via the selected transfer method.

While receiving the image file blocks, the OTAP Client application parses the image file. In case any parameter of an image file sub-element is invalid or the image file format is invalid, it sends an Error Notification to the OTAP Server and tries to restart the download process from the beginning or a known good position.

When an Image Chunk is received, its sequence number is checked and its content is parsed in the context of the image file format. If the sequence number is not as expected, then the block transfer is restarted from the last known good position. When all chunks of an Image Block are received, the next block is requested, if there are more blocks to download. When the last Image Block in an image file is received, then the image integrity is checked (the received CRC from the Image File CRC sub-element is compared to the computed CRC).

The computed image integrity initialization and intermediary value must be reset to '0' before starting or restarting an image download. If the image integrity check fails then the image download process is restarted from the beginning. If the image integrity check is successful, then the Image Download Complete message is sent to the OTAP Server, the OTACFG IFR is updated and the MCU is restarted. After the restart, the ROM bootloader kicks in and writes the new image to the flash memory, afterwards giving CPU control to the newly installed application.

If at any time during the download process, a Link Layer disconnection occurs, then the image download process is restarted from the last known good position when the link is re-established.

As noted earlier, the OTAP Client application needs to handle a lot of state information. In the demo application, all this information is held in the *otapClientData* structure of the *otapClien-*

tAppData_t type. The type is defined and the structure is initialized in the *otap_client.c* file of the application. This structure is defined and initialized differently for the OTAP Client ATT and L2CAP example applications. Mainly, the *transferMethod* member of the structure is constant and has different values for the two example applications and the L2CAP application structure has an extra member.

To receive write notifications when the OTAP Server writes the OTAP Control Point attribute and ATT Confirmations when it indicates the OTAP Control Point attribute, the OTAP Client application must register a GATT Server callback and enable write notifications for the OTAP Control Point attribute. This is done in the *BluetoothLEHost_Initialized()* function in the *otap_client_att.c/otap_client_l2cap_credit.c* file.

```
static void BluetoothLEHost_Initialized(void)
{
    /* ... Missing code here ... */

    /* Register stack callbacks */
    (void)App_RegisterGattServerCallback (BleApp_GattServerCallback);

    /* ... Missing code here ... */
}
```

The *BleApp_GattServerCallback()* function handles all incoming communication from the OTAP Server.

```
static void BleApp_GattServerCallback (deviceId_t deviceId, gattServerEvent_t* pServerEvent)
{
    switch (pServerEvent->eventType)
    {
        /* ... Missing code here ... */

        case gEvtCharacteristicCccdWritten_c:
        {
            OtapClient_CccdWritten (deviceId,
                                    pServerEvent->eventData.charCccdWrittenEvent.handle,
                                    pServerEvent->eventData.charCccdWrittenEvent.newCccd);
        }
        break;

       case gEvtAttributeWritten_c:
        {
            OtapClient_AttributeWritten (deviceId,
                                         pServerEvent->eventData.attributeWrittenEvent.handle,
                                         pServerEvent->eventData.attributeWrittenEvent.cValueLength,
                                         pServerEvent->eventData.attributeWrittenEvent.aValue);
        }
       break;

        case gEvtAttributeWrittenWithoutResponse_c:
        {
            OtapClient_AttributeWrittenWithoutResponse (deviceId,
                                                pServerEvent->eventData.attributeWrittenEvent.handle,
                                                pServerEvent->eventData.attributeWrittenEvent.cValueLength,
                                                pServerEvent->eventData.attributeWrittenEvent.aValue);
        }
        break;

        case gEvtHandleValueConfirmation_c:
        {
            OtapClient_HandleValueConfirmation (deviceId);
        }
       break;*
```

(continues on next page)

(continued from previous page)

```
        /* ... Missing code here ... */

        default:
            ; /* For MISRA compliance */
        break;
    }
}
```

When the OTAP Server Writes a CCCD the *BleApp_GattServerCallback()* function calls the *OtapClient_CccdWritten()* function which sends a New Image Info Request when the OTAP Control Point CCCD is written it – this is the starting point of OTAP transactions in the demo applications.

When an ATT Write Request is made by the OTAP Server the the *BleApp_GattServerCallback()* function calls the *OtapClient_AttributeWritten()* function which handles the data as an OTAP command. Only writes to the OTAP Control Point are handled as OTAP commands. For each command received from the OTAP Server there is a separate handler function which performs required OTAP operations. These are:

- *OtapClient_HandleNewImageNotification()*
- *OtapClient_HandleNewImageInfoResponse()*
- *OtapClient_HandleErrorNotification()*

When an ATT Write Command (GATT Write Without Response) is sent by the OTAP Server the *BleApp_GattServerCallback()* function calls the *OtapClient_AttributeWrittenWithoutResponse()* function which handles Data Chunks if the selected transfer method is ATT and returns an error if any problems are encountered. Data chunks are handled by the *OtapClient_HandleDataChunk()* function.

```
static void BleApp_AttributeWrittenWithoutResponse (deviceId_t deviceId,
                                                    uint16_t handle,
                                                    uint16_t length,
                                                    uint8_t* pValue)
{
    /* ... Missing code here ... */
    f (handle == value_otap_data)
    {
        /* ... Missing code here ... */
        if (otapClientData.transferMethod == gOtapTransferMethodAtt_c)
        {
            if (((otapCommand_t*)pValue)->cmdId == gOtapCmdIdImageChunk_c)
            {
                OtapClient_HandleDataChunk (deviceId,
                                            length,
                                            pValue);
            }
        }
        /* ... Missing code here ... */
    }
    /* ... Missing code here ... */
}
```

Finally, when an ATT Confirmation is received for a previously sent ATT Indication the *BleApp_GattServerCallback()* function calls the *OtapClient_HandleValueConfirmation()* function, which performs the necessary OTAP operations based on the last sent command to the OTAP Server. This is done using separate confirmation handling functions for each command that is sent to the OTAP Server. These functions are:

- *OtapClient_HandleNewImageInfoRequestConfirmation()*
- *OtapClient_HandleImageBlockRequestConfirmation()*

- *OtapClient_HandleImageTransferCompleteConfirmation()*
- *OtapClient_HandleErrorNotificationConfirmation()*
- *OtapClient_HandleStopImageTransferConfirmation()*

Outgoing communication from the OTAP Client to the OTAP Server is done using the *OtapCS_SendCommandToOtapServer()* function. This function writes the value to be indicated to the OTAP Control Point attribute in the GATT database and then calls the *OtapCS_SendControlPointIndication()*which checks if indications are enabled for the target device and sends the actual ATT Indication. Both functions are implemented in the *otap_service.c* file.

```
bleResult_t OtapCS_SendCommandToOtapServer (uint16_t serviceHandle,
                                            void* pCommand,
                                            uint16_t cmdLength)
{
    union
    {
        uint8_t*              uuid_char_otap_control_pointTemp;
        bleUuid_t*             bleUuidTemp;
    }bleUuidVars;

    uint16_t  handle;
    bleResult_t result;
    bleUuidVars.uuid_char_otap_control_pointTemp = uuid_char_otap_control_point;
    bleUuid_t* pUuid = bleUuidVars.bleUuidTemp;

    /* Get handle of OTAP Control Point characteristic */
    result = GattDb_FindCharValueHandleInService(serviceHandle,
                                                 gBleUuidType128_c, pUuid, &handle);

    if (result == gBleSuccess_c)
    {
        /* Write characteristic value */
        result = GattDb_WriteAttribute(handle,
                                       cmdLength,
                                       (uint8_t*)pCommand);

       if (result == gBleSuccess_c)
        {
            /* Send Command to the OTAP Server via ATT Indication */
            result = OtapCS_SendControlPointIndication (handle);
        }
    }

   return result;
}

static bleResult_t OtapCS_SendControlPointIndication (uint16_t handle)
{
    uint16_t     hCccd;
    bool_t       isIndicationActive;
    /* Get handle of CCCD */
    GattDb_FindCccdHandleForCharValueHandle (handle, &hCccd);
    Gap_CheckIndicationStatus (...);
    return GattServer_SendIndication (...);
}
```

The *otap_interface.h* file contains all the necessary information for parsing and building OTAP commands (packed command structures type definitions, command parameters enumerations, and so on).

For the two possible image transfer methods (ATT and L2CAP) there are two separate demo appli-

cations. To be able to use the L2CAP transfer method the OATP Client application must register a L2CAP LE PSM and 2 callbacks: a data callback and a control callback. This is done in the *OtapClient_Config()* function.

```
/* Register OTAP L2CAP PSM */
L2ca_RegisterLePsm (gOtap_L2capLePsm_c,
gOtapCmdImageChunkCocMaxLength_c); /*!< The negotiated MTU must be higher than the biggest data␣
↪chunk that is sent fragmented */
...
App_RegisterLeCbCallbacks(BleApp_L2capPsmDataCallback, BleApp_L2capPsmControlCallback);
```

The control callback is used to handle L2CAP LE PSM-related events: PSM disconnections, PSM Connection Complete, No peer credits, and so on.

```
static void BleApp_L2capPsmControlCallback(l2capControlMessage_t* pMessage)
{
    switch (pMessage->messageType)
    {
        case gL2ca_LePsmConnectRequest_c:
        {
            l2caLeCbConnectionRequest_t *pConnReq = &pMessage->messageData.connectionRequest;

            /* This message is unexpected on the OTAP Client, the OTAP Client sends L2CAP PSM connection
             * requests and expects L2CAP PSM connection responses.
             * Disconnect the peer. */
            (void)Gap_Disconnect (pConnReq->deviceId);

            break;
        }
        case gL2ca_LePsmConnectionComplete_c:
        {
            l2caLeCbConnectionComplete_t *pConnComplete = &pMessage->messageData.connectionComplete;

            /* Call the application PSM connection complete handler. */
            OtapClient_HandlePsmConnectionComplete (pConnComplete);

            break;
        }
        case gL2ca_LePsmDisconnectNotification_c:
        {
            l2caLeCbDisconnection_t *pCbDisconnect = &pMessage->messageData.disconnection;

            /* Call the application PSM disconnection handler. */
            OtapClient_HandlePsmDisconnection (pCbDisconnect);

            break;
        }
        case gL2ca_NoPeerCredits_c:
        {
            l2caLeCbNoPeerCredits_t *pCbNoPeerCredits = &pMessage->messageData.noPeerCredits;
            (void)L2ca_SendLeCredit (pCbNoPeerCredits->deviceId,
                                     otapClientData.l2capPsmChannelId,
                                     mAppLeCbInitialCredits_c);
            break;
        }
        case gL2ca_Error_c:
        {
            /* Handle error */
            break;
        }
        default:
            ; /* For MISRA compliance */
```

(continues on next page)

(continued from previous page)

```
            break;
    }
}
```

The OTAP Client must initiate the L2CAP PSM connection if it wants to use the L2CAP transfer method; this can be done using the *L2ca_ConnectLePsm()* function. The *L2ca_ConnectLePsm()* function is called by the *OtapClient_ContinueImageDownload()* if the transfer method is L2CAP and the PSM is found to be disconnected.

```
static void OtapClient_ContinueImageDownload (deviceId_t deviceId)
{
    /* ... Missing code here ... */
    /* Check if the L2CAP OTAP PSM is connected and if not try to connect and exit immediately. */
    if ((otapClientData.l2capPsmConnected == FALSE) &&
            (otapClientData.state != mOtapClientStateImageDownloadComplete_c))
    {
        L2ca_ConnectLePsm (gOtap_L2capLePsm_c,
                           deviceId,
                           mAppLeCbInitialCredits_c);
        bValidState = FALSE;;
    }
    /* ... Missing code here ... */
}
```

The PSM data callback *BleApp_L2capPsmDataCallback()* is used by the OTAP Client to handle incoming image file parts from the OTAP Server.

```
static void BleApp_L2capPsmDataCallback (deviceId_t     deviceId,
                                         uint16_t       lePsm,
                                         uint8_t*       pPacket,
                                         uint16_t       packetLength)
{
    OtapClient_HandleDataChunk (deviceId,
                                packetLength,
                                pPacket);
}
```

All data chunks regardless of their source (ATT or L2CAP) are handled by the *OtapClient_HandleDataChunk()* function. This function checks the validity of Image Chunk messages, parses the image file, requests the continuation or restart of the image download and triggers the bootloader when the image download is complete.

```
static void OtapClient_HandleDataChunk (deviceId_t deviceId, uint16_t length, uint8_t* pData);
```

The Image File CRC Value is computed on the fly as the image chunks are received using the *OTA_CrcCompute()* function from the *OtaSupport* module which is called by the *OtapClient_HandleDataChunk()* function. The *OTA_CrcCompute()* function has a parameter for the intermediary CRC value which must be initialized to 0 every time a new image download is started.

The actual write of the received image parts to the storage medium is also done in the *OtapClient_HandleDataChunk()* function using the *OtaSupport* module. This is achieved using the following functions:

- *OTA_StartImage()* – called before the start of writing a new image to the storage medium.
- *OTA_CancelImage()* – called whenever an error occurs and the image download process needs to be stopped/restarted from the beginning.
- *OTA_PushImageChunk()* – called to write a received image chunk to the storage medium. Note that only the Upgrade Image Sub-element of the image file is actually written to the storage medium.

- *OTA_CommitImage()* - called to set up what parts of the downloaded image are written to flash and other information for the bootloader. The Value field of the Sector Bitmap Sub-element of the Image File is given as a parameter to this function.
- *OTA_SetNewImageFlag()* - called to configure the OTACFG IFR when a new image has been successfully received. When the MCU is reset, the ROM bootloader transfers the new image from the storage medium to the program flash.

To continue the image download process after a block is transferred or to restart it after an error has occurred the *OtapClient_ContinueImageDownload()* function is called. This function is used in multiple situations during the image download process.

To summarize, an outline of the steps required to perform the image download process is shown below:

- Wait for a connection from an OTAP Server
- Wait for the OTAP Server to write the OTAP Control Point CCCD
- Ask or wait for image information from the server
- If a new image is available on the server, start the download process using the *OtapClient_ContinueImageDownload()* function.
  - If the transfer method is L2CAP CoC, then initiate a PSM connection to the OTAP Server
- Repeat while image download is not complete.
  - Wait for image chunks.
  - *Call the OtapClient_HandleDataChunk()* function for all received image chunks regardless of the selected transfer method.
    - Check image file header integrity using the *OtapClient_IsImageFileHeaderValid()* function.
    - Write the Upgrade Image Sub-element to the storage medium using *OtaSupport* module functions.
    - When the download is complete, check image integrity.
      - If the integrity check is successful, commit the image using the Sector Bitmap Sub-element and trigger the bootloader
      - If integrity check fails, restart the image download from the beginning
    - If the download is not complete, ask for a new image chunk.
  - If any error occurs during the processing of the image chunk, restart the download from the last known good position.
- If an image was successfully downloaded and transferred to the storage medium and the bootloader triggered, then reset the MCU to start the flashing process of the new image.

Secured OTAP

The security features of the KW45 devices enable them to use secured OTAP, meaning the new images can be authenticated and encrypted. The decryption/authentication keys are programmed into hardware fuses. For information on how to prepare the board, refer to the accompanying document related to board provisioning. For information on how to obtain the secured image, refer to the *Bluetooth Low Energy Demo Applications User's Guide (BLEDAUG)*.

Parent topic:*Over the Air Programming (OTAP)*

Creating a Bluetooth LE application when the Host Stack runs on another processor

This section describes how to create a Bluetooth Low Energy application (host), when the Bluetooth Low Energy Host Stack is running on another processor (blackbox). The section alsp provides sample code to explain how to achieve this.

The supported serial interfaces between the two chips (application and the Bluetooth Low Energy Host Stack) are UART, SPI, or USB.

Typical applications employing Bluetooth LE Host Stack blackboxes are host systems such as a PC tool or an embedded system that has an application implementation. This chapter describes an embedded application.

For more information, refer to *Bluetooth Low Energy Host Stack FSCI Reference Manual*. This document provides explicit information on exercising the Bluetooth Low Energy Host Stack functionality through a serial communication interface to a host system.

Serial manager and FSCI configuration

For creating an embedded application that communicates with the Bluetooth Low Energy Host Stack using the serial interface, the following steps must be done:

Serial manager initialization

The function that must be called for Serial Manager initialization is located in *SerialManager.h*:

```
/* Init serial manager */
SerialManager_Init();
```

Parent topic: Serial manager and FSCI configuration

FSCI configuration and initialization

By default, the FSCI module is disabled. It must be enabled by setting gFsciIncluded_c to 1. Also, gFsciLenHas2Bytes_c must be set to 1 because Bluetooth Low Energy Host Stack interface commands and events need serial packets bigger than 255 octets.

For more information on the following configuration parameters, refer to the FSCI chapter of the *Connectivity Framework Reference Manual*.

To configure the FSCI module, the following parameters can be set on both the Bluetooth Low Energy Application project and the Bluetooth Low Energy FSCI blackbox:

```
/* Enable/Disable FSCI */
#define gFsciIncluded_c                 1

/* Enable/Disable FSCI Low Power Commands*/
#define gFSCI_IncludeLpmCommands_c      0

/* Defines FSCI length - set this to FALSE is FSCI length has 1 byte */
#define gFsciLenHas2Bytes_c             1

/* Defines FSCI maximum payload length */
#define gFsciMaxPayloadLen_c            1660

/* Enable/Disable Ack transmission */
#define gFsciTxAck_c                    0

/* Enable/Disable Ack reception */
#define gFsciRxAck_c                    0

/* Enable FSCI Rx restart with timeout */
#define gFsciRxTimeout_c                1
#define mFsciRxTimeoutUsePolling_c      1
```

(continues on next page)

(continued from previous page)

```
/* Use Misra Compliant version of FSCI module */
#define gFsciUseDedicatedTask_c          1

/* FSCI task size */
#if defined(DEBUG)
#define gFsciTaskStackSize_c             4600
#else
#define gFsciTaskStackSize_c             2600
#endif
```

To perform the FSCI module initialization, the following code can be used:

```
/* Define fsci serial manager handle */
  #if defined(gFsciIncluded_c) && (gFsciIncluded_c > 0)
    extern serial_handle_t g_fsciHandleList[gFsciIncluded_c];
  #endif /*gFsciIncluded_c > 0*/

void BluetoothLEHost_AppInit(void)
{
    /* Init FSCI */
    FSCI_commInit( g_fsciHandleList );

    /* Register BLE handlers in FSCI */
    fsciBleRegister(0);
    ...
}
```

Parent topic: Serial manager and FSCI configuration

FSCI handlers (GAP, GATT, and GATTDB) registration

For receiving messages from all the Bluetooth Low Energy Host Stack serial interfacing layers (GAP, GATT, and GATTDB), a function handler must be registered in FSCI for each layer:

```
fsciBleRegister(0);
```

Parent topic: Serial manager and FSCI configuration

Parent topic:*Creating a Bluetooth LE application when the Host Stack runs on another processor*

Bluetooth Low Energy Host Stack initialization

The Bluetooth Low Energy Host Stack must be initialized when platform setup is complete and all RTOS tasks have been started. This initialization is done by restarting the black-box using a FSCI CPU Reset Request command. This is performed automatically by the ***Ble_Initialize(App_GenericCallback)*** function.

```
/* Send FSCI CPU reset command to BlackBox */
FSCI_transmitPayload(gFSCI_ReqOpcodeGroup_c, mFsciMsgResetCPUReq_c, NULL, 0, fsciInterface);
```

The completion of the Bluetooth Low Energy Host Stack initialization is signaled by the reception of the *GAP-GenericEventInitializationComplete.Indication* event (over the serial communication interface, in FSCI). The *Bluetooth Low Energy-HostInitialize.Request* command is not required to be sent to the blackbox (the entire initialization is performed by the blackbox, when it resets).

Parent topic:*Creating a Bluetooth LE application when the Host Stack runs on another processor*

GATT database configuration

The GATT database always resides on the same processor as the entire Bluetooth Low Energy Host Stack, so the attributes must be added by the host application using the serial communication interface.

To create a GATT database remotely, *GATTDBDynamic* commands must be used. The GATTDBDynamic API is provided to the user that performs all the required memory allocations and sends the FSCI commands to the blackbox. The result of the operation is returned, including optionally the service, characteristic, and 'cccd' handles returned by the blackbox.

Current supported API for adding services is the following:

```
bleResult_t GattDbDynamic_AddGattService (gattServiceHandles_t* pOutServiceHandles);
bleResult_t GattDbDynamic_AddGapService (gapServiceHandles_t* pOutServiceHandles);
bleResult_t GattDbDynamic_AddIpssService (ipssServiceHandles_t* pOutServiceHandles);
bleResult_t GattDbDynamic_AddHeartRateService (heartRateServiceHandles_t* pOutServiceHandles);
bleResult_t GattDbDynamic_AddBatteryService (batteryServiceHandles_t* pOutServiceHandles);
bleResult_t GattDbDynamic_AddDeviceInformationService (deviceInfoServiceHandles_t*␣
↪pOutServiceHandles);
```

The service handles are optional.

Also, a generic function is provided, so that the user can add any generic service to the database:

```
bleResult_t GattDbDynamic_AddServiceInDatabase (serviceInfo_t* pServiceInfo);
```

Usually, a Bluetooth Low Energy Application is ported from a single chip solution, where the Bluetooth Low Energy Application and the Bluetooth Low Energy stack reside on the same processor and the GATT database is populated statically. The user should remove all the attribute handles from any structure and replace them with *gGattDbInvalidHandle_d*. The attribute handles should be populated after the services are added dynamically to the database with the handles returned by the previous API.

Parent topic:*Creating a Bluetooth LE application when the Host Stack runs on another processor*

FSCI host layer

The Bluetooth Low Energy GAP, GATT, GATTDB, and L2CAP APIs are included in the Bluetooth Low Energy interface. When these APIs reside on a separate processor than the Bluetooth Low Energy stack, they are implemented as an FSCI Host Layer that should be added to the Bluetooth Low Energy Application project.

This layer is responsible for serializing API to the corresponding FSCI commands. The layer also sends these APIs to the blackbox, receives and deserializes FSCI statuses and events, presents them to the Bluetooth Low Energy Application, and arbitrates access from multiple tasks to the serial interface.

All the GAP, GATT, GATTDB, and L2CAP APIs are executed asynchronously, so the user context blocks waiting for the response from the blackbox. The response can be the status of the request or optionally an FSCI event, which includes the output parameters of a synchronous function.

There are also functions without parameters that are not executed synchronously and they are provided asynchronously through a later FSCI event. It is the responsibility of the FSCI Host layer to keep the application-allocated memory between the time of the request and the completion of the event with the actual values of the output parameters and populate them accordingly.

The Bluetooth Low Energy API execution inside the FSCI Host layer first waits for gaining access to the serial interface through a mutex. Once the access is gained, the FSCI request is sent to the serial interface to the blackbox. Then, by default, the serial interface response is received by polling until the whole FSCI packet is received. The other option available is to block the user task to wait for an OS event that is set by the FSCI module when the status is received. For more information on the FSCI module, see the Connectivity Framework Reference Manual. See *References*.

The API can have output parameters that are to be received immediately after the status of the request. In such as case, if the status of the request is 'success', the polling mechanism continues to receive the whole FSCI packet of the Bluetooth Low Energy event. The output parameters are obtained and the values are filled in the memory space provided by the application. After obtaining the status and optionally the event, the execution of the request is considered completed, the

mutex to the serial interface is unlocked, and the execution flow is returned to the user calling context.

Parent topic:*Creating a Bluetooth LE application when the Host Stack runs on another processor*

Intrusion Detection System

Overview

The Intrusion Detection System (IDS) provides a comprehensive security monitoring framework for Bluetooth Low Energy applications. This interface defines various security events that can be detected across different layers of the Bluetooth LE stack and provides mechanisms to register callbacks and handle security incidents.

Event Types

The idsEventType_t enumeration defines various security events that can be detected:

Pairing-Related Events

gSecEvt_Sweyntooth_MaxEncKeySize_c (BIT0)

- **Attack**: Sweyntooth - Max Encryption Key Size
- **Target**: Pairing process
- **Stack Location**: Host
- **Description**: Attacker sends a Pairing Request with a value for the Encryption Key Size field which exceeds the maximum allowed (16 bytes), hoping to later trigger a buffer overflow on the victim device.
- **Preventive Action**: Sanity check the fields of received SMP messages.

gSecEvt_DhKeyCheckZero_c (BIT1)

- **Attack**: Deviating Behavior - DHKey Check Zero
- **Target**: Pairing process
- **Stack Location**: Host
- **Description**: During the pairing process, the attacker sends a DHKey Check message with all fields set to zero, hoping to bypass this step of the process.
- **Preventive Action**: Sanity check the fields of received SMP messages.

gSecEvt_UnexpectedSmpMessage_c (BIT2)

- **Attack**: Deviating Behavior - Unexpected SMP message
- **Target**: Pairing process
- **Stack Location**: Host
- **Description**: During the pairing process, an SMP message is received out of turn. Attacker may try to bypass one of the steps of the process.
- **Preventive Action**: Ensure the SMP state machine does not allow out of turn messages.

gSecEvt_IdenticalPeerPublicKey_c (BIT3)

- **Attack**: ANSSI - Identical Public Key
- **Target**: Pairing process
- **Stack Location**: Host

- **Description**: During the pairing process, the attacker sends a Public Key whose X coordinate is equal to the X coordinate of the victim device's Public Key. This is a precursor step to a successful attack.
- **Preventive Action**: Check the peer's Public Key X coordinate and do not accept it if it is equal to our own.

gSecEvt_ForcedRepairing_c (BIT13)

- **Attack**: Forced re-pairing
- **Target**: Pairing process
- **Stack Location**: Host
- **Description**: A bonded peer rejects link encryption and, if it is a GAP central, attempts to pair again. This could indicate an attempt to downgrade the security of an existing connection or to force a new pairing process that may be vulnerable to attacks.
- **Preventive action**: Signal the application and allow it to decide whether to accept the new pairing request or terminate the connection.

gSecEvt_KNOB_c (BIT16)

- **Attack**: Key Negotiation over Bluetooth
- **Target**: Pairing process
- **Stack Location**: Host
- **Description**: During the pairing process, an attacker attempts to negotiate a lower encryption key size than the minimum allowed (7 bytes), weakening the security of the connection.
- **Preventive Action**: Validate that the negotiated key size meets minimum security requirements.

gSecEvt_InvalidPublicKey_c (BIT18)

- **Attack**: Invalid public key
- **Target**: Pairing process
- **Stack Location**: Host
- **Description**: During the pairing process, the attacker sends an invalid Public Key that does not conform to the expected elliptic curve parameters, attempting to cause processing errors or bypass key validation checks.
- **Preventive Action**: Validate that the received Public Key conforms to the expected elliptic curve and reject any malformed keys.

gSecEvt_WrongConfirmValue_c (BIT19)

- **Attack**: Wrong confirm value
- **Target**: Pairing process
- **Stack Location**: Host
- **Description**: During the pairing process, the attacker sends a Confirm Value that does not match the expected cryptographic computation, attempting to bypass the confirmation step of the pairing process.
- **Preventive Action**: Verify that the received Confirm Value matches the computed expected value and reject the pairing if it does not.

gSecEvt_DHKeyCheckFailed_c (BIT20)

- **Attack**: DH Key Check failed
- **Target**: Pairing process
- **Stack Location**: Host

- **Description**: During the pairing process, the attacker sends a DHKey Check message that fails cryptographic verification, attempting to bypass the key confirmation step of the pairing process.
- **Preventive Action**: Verify that the received DHKey Check value matches the computed expected value and reject the pairing if it does not.

gSecEvt_SameConfirmValue_c (BIT21)

- **Attack**: Confirm Value Replay Attack (Same Confirm Value)
- **Target**: Pairing process
- **Stack Location**: Host
- **Description**: During Legacy Pairing Phase 2, the attacker (acting as Responder) sends LP_CONFIRM_R equal to LP_CONFIRM_I received from the Initiator, attempting to bypass the confirm value verification step and force the Initiator into an incorrect STK encryption attempt. Per Core Spec 6.3 Section 2.3.5.5, the Initiator SHALL verify that LP_CONFIRM_R is not equal to LP_CONFIRM_I.
- **Preventive Action**: Verify that LP_CONFIRM_R != LP_CONFIRM_I and reject the pairing with Confirm Value Failed (0x04) if equal. The IDS event allows the application to take additional defensive action (e.g., disconnect, block device).

Connection-Related Events

gSecEvt_MicFailureDisconnect_c (BIT5)

- **Attack**: MIC Failure Disconnect
- **Target**: Connection
- **Stack Location**: Host
- **Description**: A packet received from the peer device fails MIC (Message Integrity Check) verification, indicating potential tampering or corruption of the encrypted data. This could indicate an active attack or a corrupted connection.
- **Preventive Action**: Disconnect from the peer device and report the security event for monitoring.

gSecEvt_EncReqNonBonded_c (BIT6)

- **Attack**: Encryption Request from Non-Bonded Device
- **Target**: Connection
- **Stack Location**: Host
- **Description**: An encryption request is received from a device that is not bonded with the local device. This could indicate an attempt to establish an encrypted connection without proper pairing, potentially allowing unauthorized access.
- **Preventive Action**: Reject encryption requests from non-bonded devices and require proper pairing before allowing encrypted connections.

gSecEvt_MalformedL2cap_c (BIT7)

- **Attack**: Malformed L2CAP Packet
- **Target**: Connection
- **Stack Location**: Host
- **Description**: An L2CAP packet is received with malformed structure or invalid parameters, potentially indicating an attempt to exploit protocol parsing vulnerabilities or cause processing errors.

- **Preventive Action**: Validate L2CAP packet structure and parameters, reject malformed packets, and disconnect from the peer device if violations are detected.

gSecEvt_MalformedAtt_c **(BIT8)**

- **Attack**: Malformed ATT Packet
- **Target**: Connection
- **Stack Location**: Host
- **Description**: An ATT packet is received with malformed structure or invalid parameters, potentially indicating an attempt to exploit protocol parsing vulnerabilities, cause processing errors, or bypass attribute access controls.
- **Preventive Action**: Validate ATT packet structure and parameters, reject malformed packets, and disconnect from the peer device if violations are detected.

gSecEvt_L2capFragmentsExceedMTU_c **(BIT14)**

- **Attack**: Blue Frag
- **Target**: Connection
- **Stack Location**: Host
- **Description**: An attacker sends L2CAP fragments that exceed the negotiated Maximum Transmission Unit (MTU), attempting to cause buffer overflow vulnerabilities or bypass MTU validation checks during packet reassembly.
- **Preventive Action**: Validate that L2CAP fragment sizes do not exceed the negotiated MTU, reject oversized fragments, and disconnect from the peer device if violations are detected.

Application-Related Events

gSecEvt_UnauthenticatedServer_c **(BIT4)**

- **Attack**: BLESA
- **Target**: Application
- **Stack Location**: Application
- **Description**: An attacker attempts to access GATT database attributes or services without proper authentication, potentially allowing unauthorized read/write operations on sensitive characteristics.
- **Preventive Action**: Ensure that the peer is properly authenticated before allowing access to protected attributes, enforce attribute-level access controls, and disconnect from the peer device if unauthorized access attempts are detected. This is an application-level operation.

gSecEvt_UnauthorizedDbAccess_c **(BIT9)**

- **Attack**: Unauthorized GATT Database Access
- **Target**: Application
- **Stack Location**: Application
- **Description**: An attacker attempts to perform unauthorized read or write operations on GATT database attributes without proper authorization, potentially allowing access to sensitive data or modification of critical characteristics.
- **Preventive Action**: Enforce attribute-level authorization checks, validate that the peer has the required permissions before allowing read/write operations, and disconnect from the peer device if unauthorized access attempts are detected. This is an application-level operation.

Usage Example

The user must set the gIntrusionDetectionSystem_d define to 1 in the application's app_preinclude.h header. The IDS_RegisterCallback() API is used to register a callback for events specified via an event mask.

```
/* Register for specific security events */
uint32_t eventMask = gSecEvt_MicFailureDisconnect_c |
                     gSecEvt_UnexpectedSmpMessage_c |
                     gSecEvt_MalformedAtt_c;

IDS_RegisterCallback(securityEventHandler, eventMask);
```

The security events can then be handled in the registered callback.

```
/* Callback function to handle security events */
void securityEventHandler(idsEventData_t *pEventData) {
    /* Handle the security event based on type */
    switch(pEventData->type) {
        case gSecEvt_MicFailureDisconnect_c:
            /* Handle MIC failure */
            break;
        case gSecEvt_UnexpectedSmpMessage_c:
            /* Handle unexpected SMP message */
            break;
        /* ... handle other events */
    }
}
```

The IDS provides comprehensive security monitoring capabilities for Bluetooth LE applications, helping to detect and respond to various known attack vectors and security vulnerabilities.

Acronyms and abbreviations

The following acronyms are used in this document.

Acronym	Description
Bluetooth LE	Bluetooth Low Energy
CCCD	Client Characteristic Configuration Descriptor
ELKE	EdgeLock Secure Enclave
FSCI	Framework Serial Connectivity Interface
GAP	Generic Access Profile
GATT	Generic Attribute Profile
GATTDB	Generic Attribute Profile Database
HCI	Host Controller Interface
IRK	Identity Resolving Key
LTK	Long Term Key
LL	Link Layer
L2CAP	Logical Link Control and Adaptation Protocol
MTU	Maximum Transmission Unit
PDU	Protocol Data Unit
PAwR	Periodic Advertising with Responses
RPA	Resolvable Private Address
RSSI	Received Signal Strength Indicator
RTOS	Real Time Operating System
RX	Receiver
SDK	Software Development Kit
TX	Transmitter
WFI	Wait For Interrupt

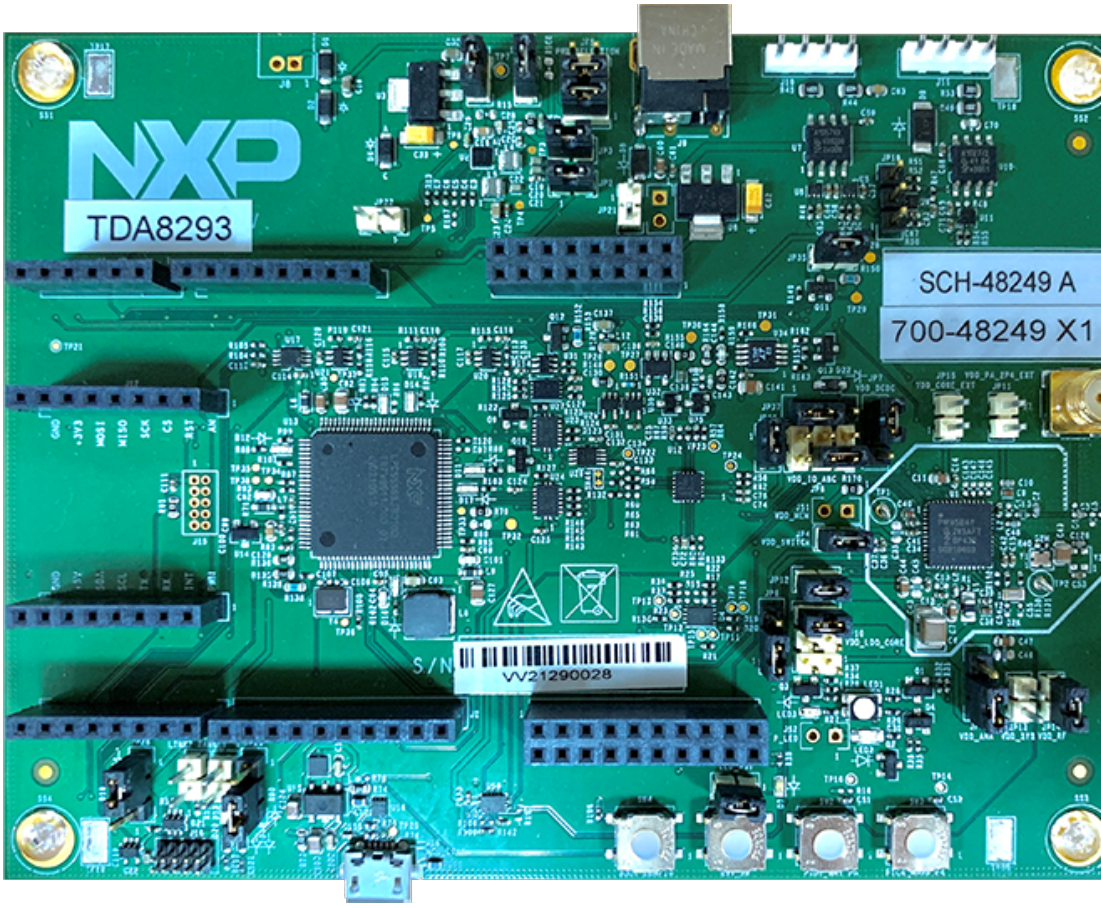
Revision history

This table summarizes revisions to this document.

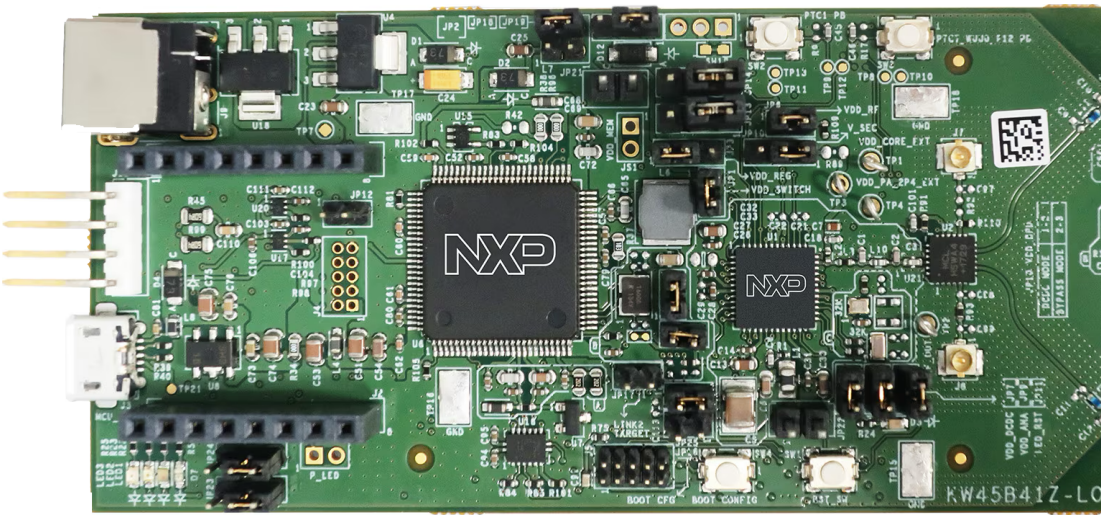
Document ID	Release date	Description
UG10184 v.1.1	06 April 2026	Added support for FRDM-KW43 platform. Updated Advanced Secure Mode section
UG10184 v.1.0	26 November 2024	Document is aligned to KW47 EAR 2.1 24.12.00-pvw2 release

Legal information



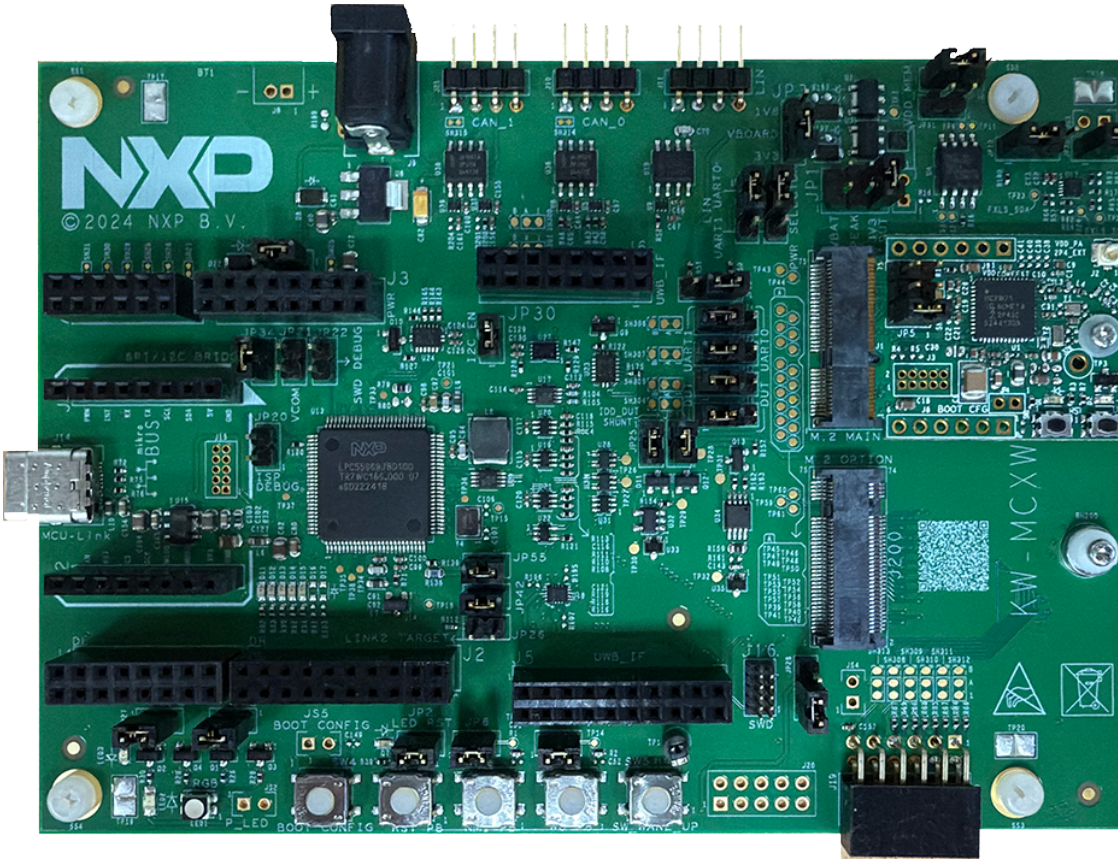
KW45, MCXW71, KW47, MCXW72, KW43 Bluetooth Low Energy Software Quick Start Guide Introduction

This document briefly describes the process of using NXP Bluetooth Low Energy Software for the KW45, MCXW71, KW47, MCXW72 and KW43 wireless microcontroller platforms (version 1.1.0). It lists the hardware setup and steps for building and usage of the provided demo applications.



Hardware setup

The examples described in this document use a KW45B41Z-EVK, KW45B41Z-LOC, MCX-W71-EVK, FRDM-MCXW71, KW47-EVK, KW47-LOC, KW43-LOC, MCX-W72-EVK, FRDM-MCXW72 or FRDM-KW43 as the development platform, as shown in the figures below.



- The default interface selected in the IAR Embedded Workbench for Arm projects included in this release is below:
  - CMSIS-DAP for kw45b41zevk, kw45b41zloc, mcxw71evk, frdmmcxw71, frdm-kw43 platforms.
  - JLink for kw47evk, kw47loc, kw43loc, mcxw72evk, frdmmcxw72 and frdm-kw43 platforms.
- Use jumpers to configure the boards in one of the available power configurations (refer to the specific board documentation).
- On all boards, the OpenSDA USB port is connected to a Windows PC. The OpenSDA chip on the board requires flashing with appropriate firmware with debugging and virtual serial COM port capabilities.

Getting Started with west Build Environment

These steps are intended for **GitHub users** working with Bluetooth Low Energy (BLE) demo applications from the GitHub MCUXpresso SDK repository.

Option 1: Using west

Follow the steps in the order presented in Getting Started with MCUXpresso SDK Repository to install the west environment.

Option 2: Using Repository ZIP Download

1. **Download the Repository ZIP**
   - Navigate to https://mcuxpresso.nxp.com/
   - Search for your board (e.g., KW47-EVK, FRDM-MCXW71, KW45B41Z-EVK)
   - Click on your board from the search results
   - Click **ARMGCC**

- Select the components you need (ensure Bluetooth Low Energy is selected)
- Click **BUILD SDK**
- Extract the downloaded ZIP file to your workspace

2. **Locate Bluetooth Examples** Bluetooth examples
3. **Install west (Required for Building)**

   Follow Getting Started with MCUXpresso SDK Repository to install west.
4. **Build from Repository ZIP**

   Navigate to the SDK root directory and use west build commands as shown below.

Note: The Repository ZIP includes all dependencies pre-configured for your board.

Command Line to Generate/Build Projects

Example: w_uart **on** kw47evk

To build the w_uart example for the kw47evk board using the IAR toolchain and generate an IDE project, use the following command:

```
west build -b kw47evk boards/kw47evk/wireless_examples/bluetooth/w_uart/freertos/ --toolchain=iar -t␣
↪guiproject -Dcore_id=cm33_core0 --pristine
```

Note: If using Repository ZIP download, navigate to the SDK root directory before running west commands.

Argument	Description
-b kw47evk	Specifies the board
--toolchain=iar	Specifies the toolchain (default is armgcc)
-t guiproject	Creates an IDE project
-Dcore_id=cm33_core0	Core ID, if available
--pristine	Cleans the build folder before building

Use the following steps in order to build and flash the BLE software demo applications on all toolchains presented in:

- Building and flashing the BLE software demo applications using IAR Embedded Workbench
- Building and flashing the BLE Software Demo applications using MCUXpresso IDE
- Building and flashing the BLE software demo applications using Visual Studio Code

Installing the Connectivity Package

To install the Connectivity Package, configure and download the package archive from the staging system on the https://mcuxpresso.nxp.com website. You can simply download the precreated package archive if it is available on the same website.

Note: Use the default location for the package (C:\NXP) and create a subfolder there specific to each device and release.

Note: Prior to loading any wireless SDK example, update your NBU image with the provided binaries in the following folder of the SDK: ../middleware/wireless/ble_controller/bin

Building the binaries

This section describes the necessary steps for obtaining the binary files for usage with the boards.

Prerequisites

To build any of the demo applications, you need the following toolchain:

- IAR Embedded Workbench for Arm (details in release note)
- Visual Studio Code with "*MCUXpresso for Visual Studio Code*" extension (details in release note)
- Teraterm (version 4.105 or higher)

The Connectivity Software Package does not include support for any other toolchains. The packages must be built with the debug configuration to enable debugging information. This package includes various sample applications that can be used as a starting point.

Conventions for building the *wireless_UART* application.

The following sections present the steps required for building the *wireless_UART* application. All applications can be found using the following placeholders for text:

- <connectivity_path>: represents the root path for the SDK.
- <board>: represents the target board for the demo app, "kw47evk" in this case.
- <RTOS>: represents the scheduler or RTOS used by the app; it can be either "bm" or "freertos".
- <demo_app>: represents the demo application name.
- <IDE>: represents the integrated development environment used to build projects; "iar" in this case.
- <core_id>: represents the target CPU on which the application will run, "cm33_core0" in this case (applicable only on KW47-EVK, KW47-LOC, KW43-LOC, MCX-W72-EVK, FRDM-MCXW72 and FRDM-KW43 boards).
- The general folder structure of the demo applications is the following:

  <connectivity_path>\boars\<board>\wireless_examples\bluetooth\<demo_app>\<core_id>\<RTOS>\<IDE>

Selected application: w_uart

Board: One of the following boards:

- **kw45b41zevk** (for this guide)
- kw45b41zloc
- frdmmcxw71
- kw47evk
- kw47loc
- kw43loc
- mcxw72evk
- frdmmcxw72
- frdm-kw43

RTOS: FreeRTOS

Resulting location:

<connectivity_path>\boards\<kw45b41zevk / kw45b41zloc / frdmmcxw71 / kw47evk / kw47loc / kw43loc / mcxw72evk / frdmmcxw72/frdm-kw43>\wireless_examples\bluetooth\w_uart\freertos\<IDE>

Building and flashing BLE demo applications using IAR Embedded Workbench

This guide shows how to build and flash Bluetooth Low Energy demo applications using IAR Embedded Workbench and the west build environment.

Prerequisites

- **west build environment** - Follow Getting Started with MCUXpresso SDK Repository
- **IAR Embedded Workbench for Arm** (see release notes for version)
- **GitHub MCUXpresso SDK repository** cloned locally (west init -m https://github.com/nxp-mcuxpresso/mcuxsdk-manifests.git)

Step 1: Generate IAR Project

Use west build to generate the IAR project:

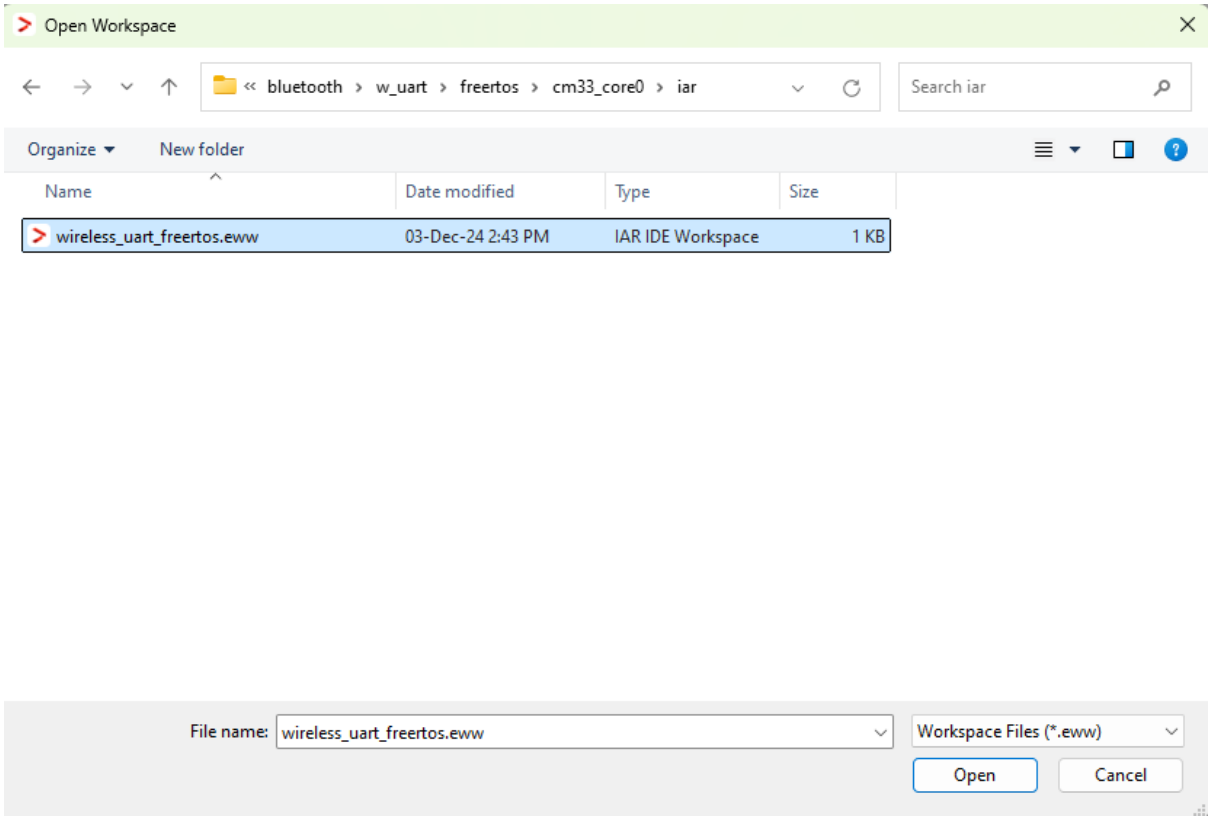
```
west build -b <board> <application_path> --toolchain=iar -t guiproject -Dcore_id=<core_id> --pristine
```

Example for Wireless UART on KW47-EVK:

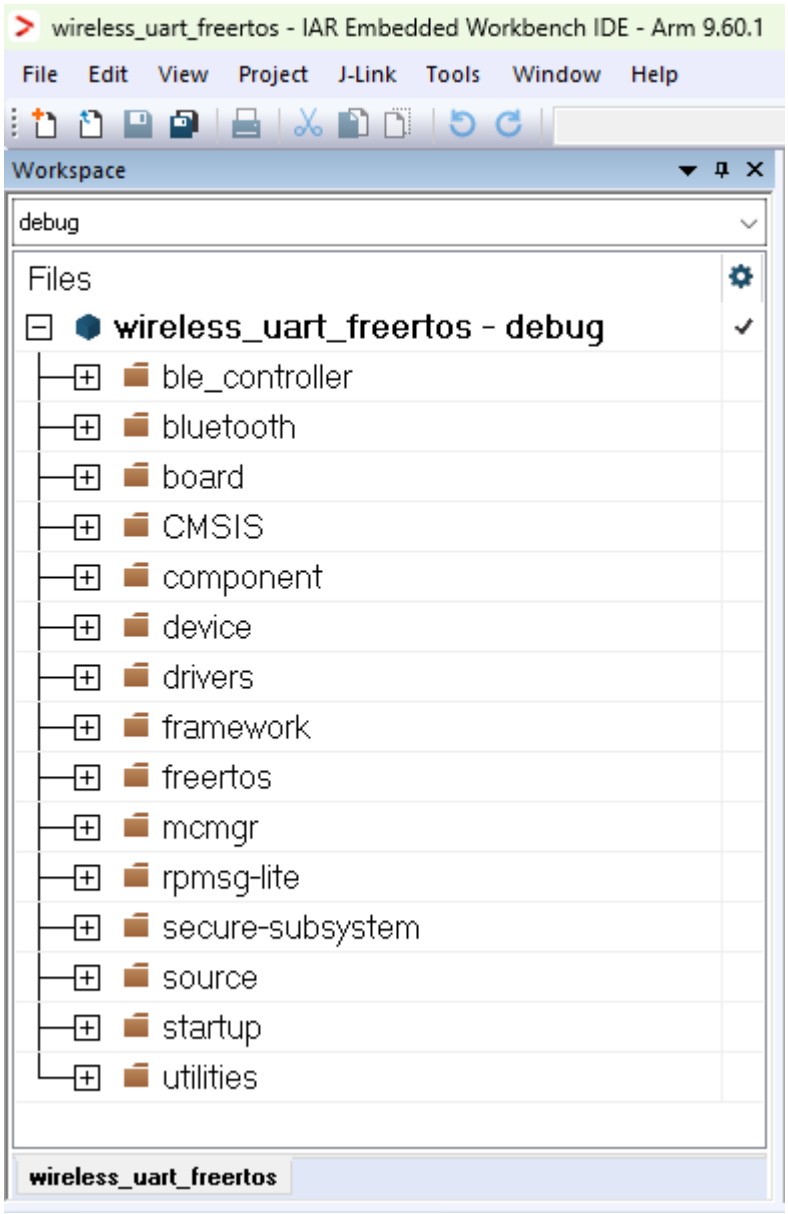
```
west build -b kw47evk examples/wireless_examples/bluetooth/w_uart/freertos/ --toolchain=iar -t guiproject -
↪Dcore_id=cm33_core0 --pristine
```

Parameters:

Parameter	Description
-b <board>	Target board (kw47evk, kw47loc, kw43loc, frdmkw43, frdmmcxw72, etc.)
--toolchain=iar	Use IAR toolchain
-t guiproject	Generate IAR workspace
-Dcore_id=cm33_core0	CPU core (for KW47, MCXW72)
--pristine	Clean build



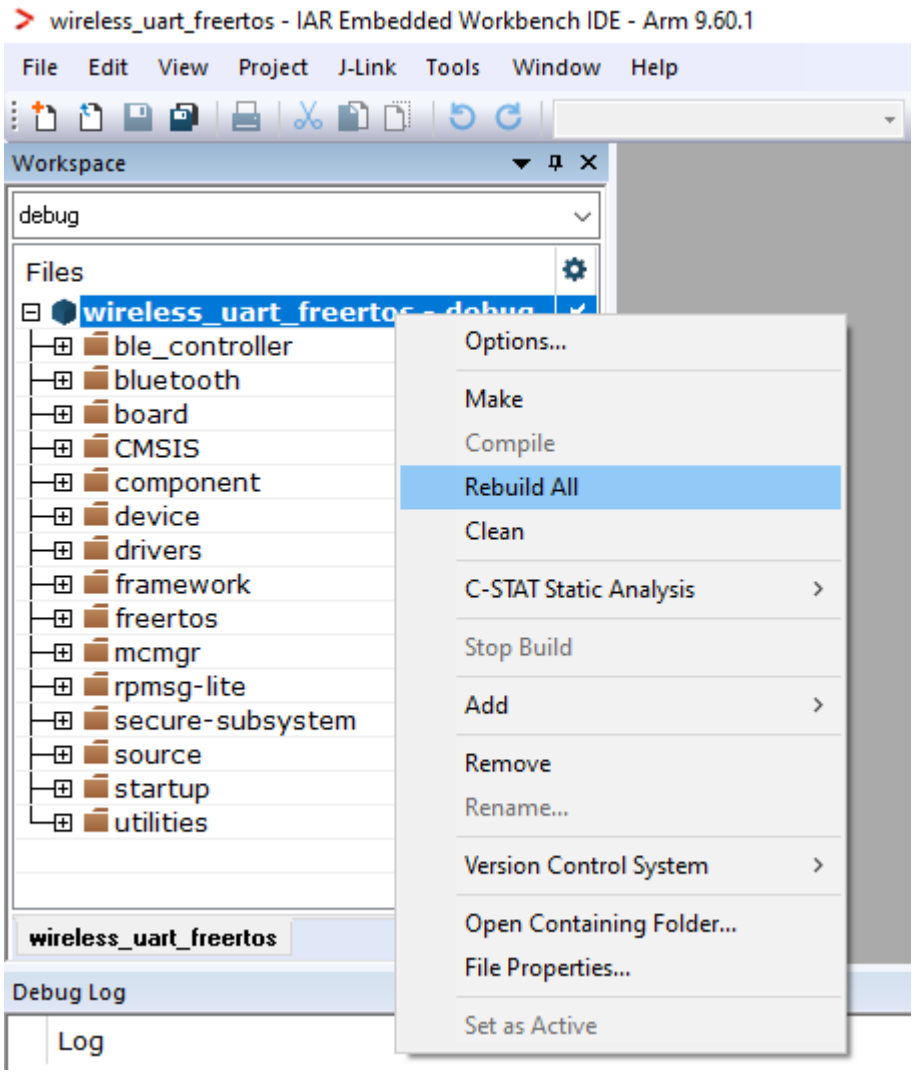
Supported boards: kw47evk, kw47loc, kw43loc, frdmmcxw71, frdmmcxw72, mcxw72evk, frdmkw43.



Output: IAR workspace at build/iar/<project_name>.eww

Note: The west build command builds in debug mode by default. To build in release mode, add --config=release to the command.

Step 2: Open IAR Workspace

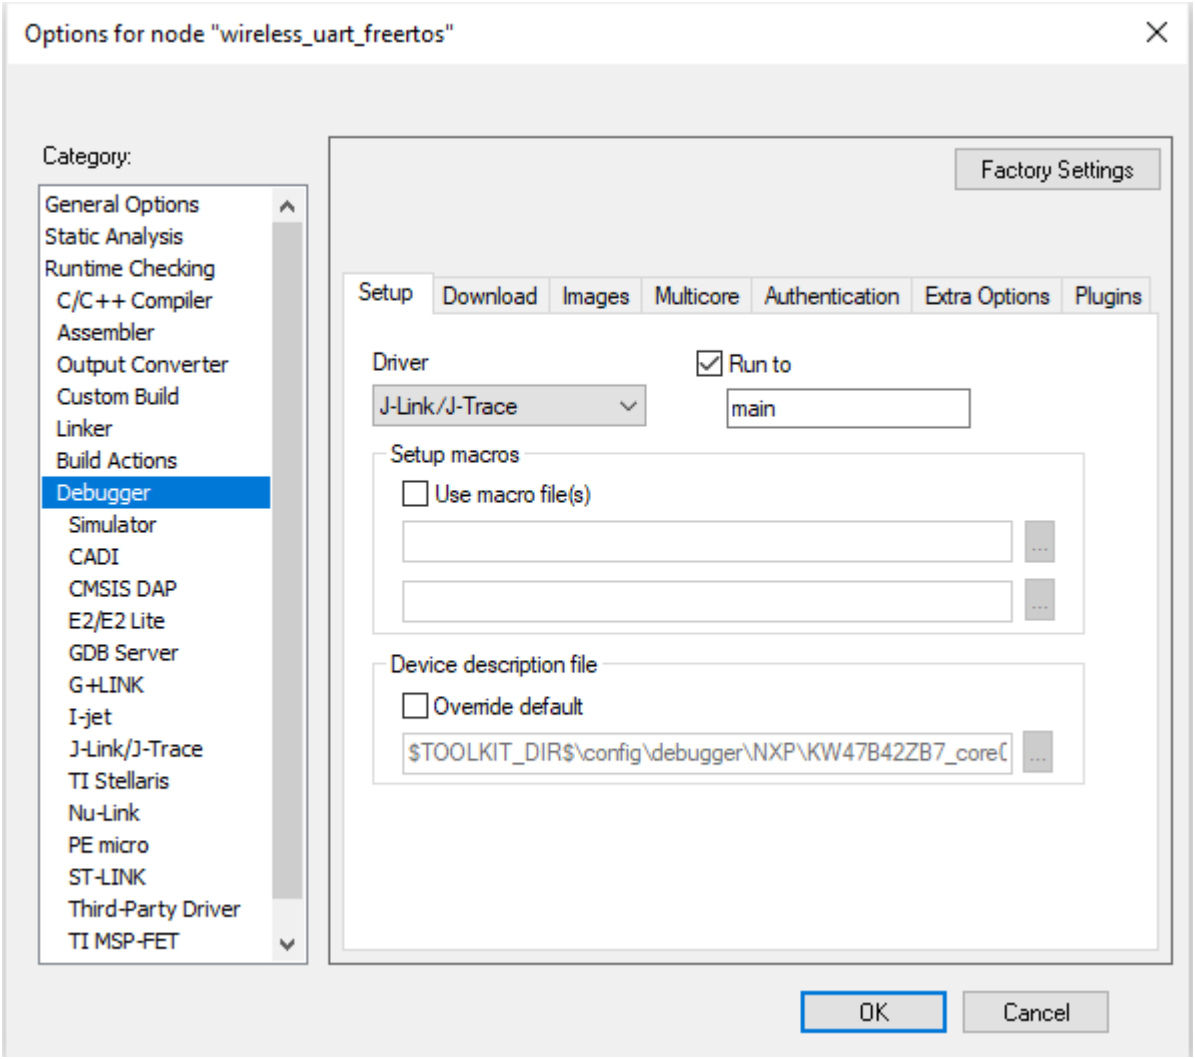


1. Navigate to build/iar/
2. Open the .eww file in IAR Embedded Workbench

Open Workspace
bluetooth › w_uart › freertos › cm33_core0 › iar
Search iar
Organize
New folder
Name
Date modified
Type
Size
wireless_uart_freertos.eww
03-Dec-24 2:43 PM
IAR IDE Workspace
1 KB
File name:
wireless_uart_freertos.eww
Workspace Files (*.eww)
Open
Cancel

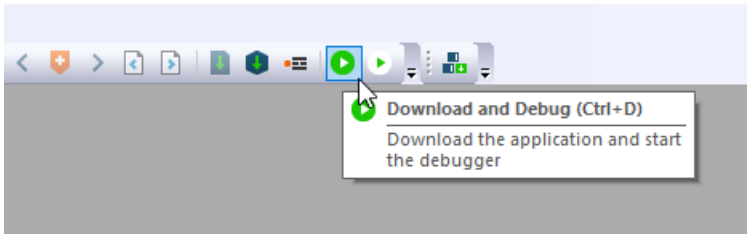
Step 3: Build Project

Build the project using **Project** > **Make** or **F7**.



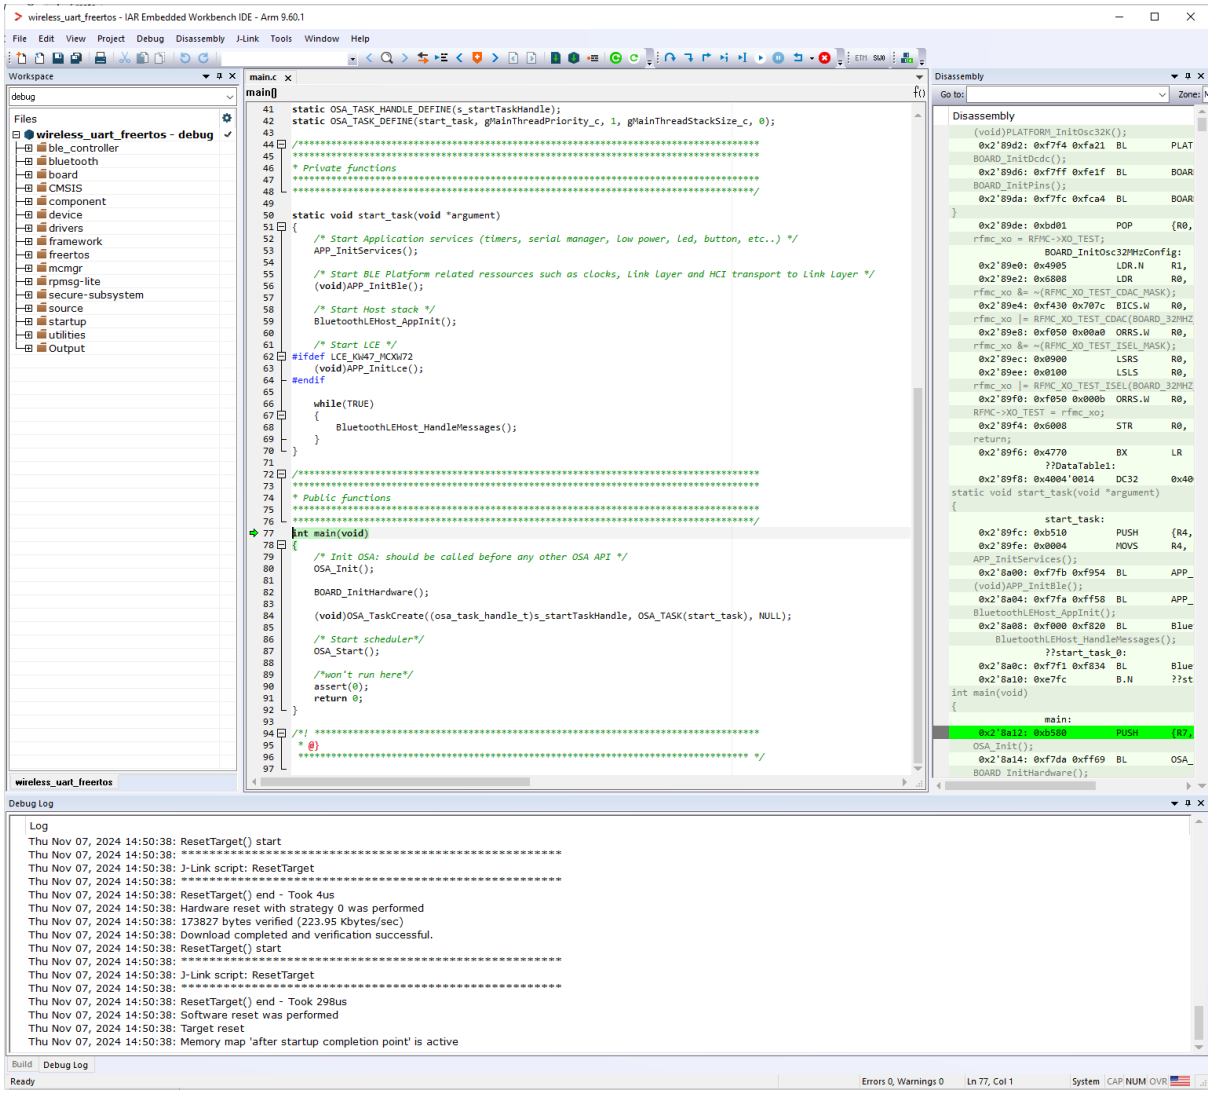
Step 4: Configure Debugger

Go to **Project** > **Options (Alt+F7)** > **Debugger** > **Setup** > **Driver**



Select debugger:

- **CMSIS-DAP** for kw45b41zevk, mcxw71evk, frdmmcxw71
- **J-Link** for kw47evk, kw47loc, kw43loc, mcxw72evk, frdmmcxw72, frdmkw43



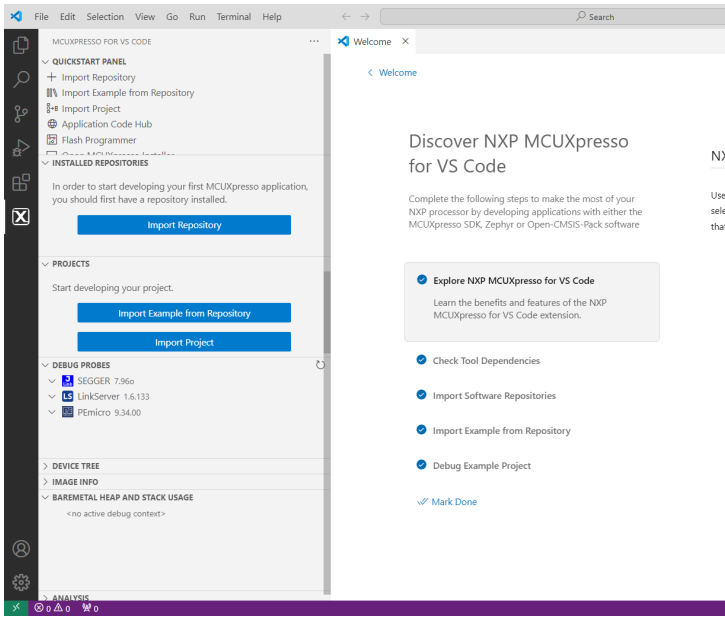
Step 5: Flash and Debug

Click **Download and Debug** or press **Ctrl+D**.

Step 6: Run Application

Press **Go (F5)** to start the application.

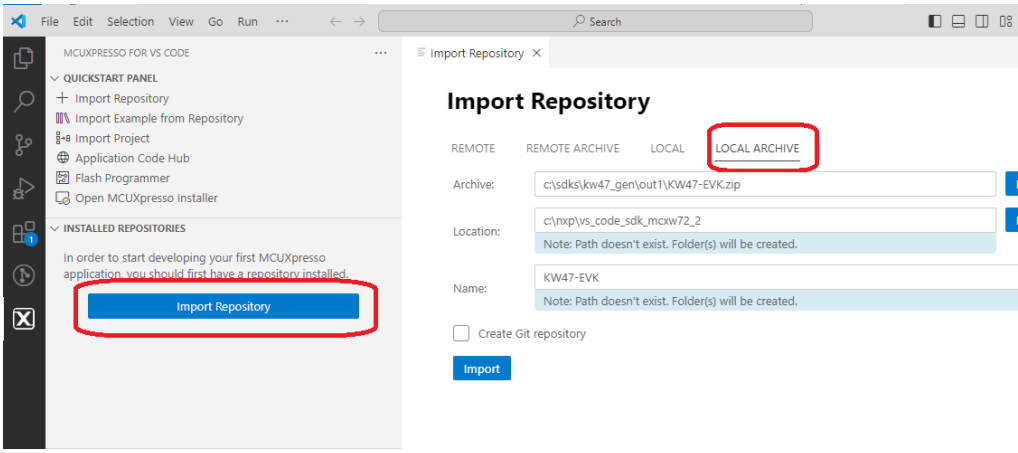
Notes



- To rebuild after configuration changes, run west build with --pristine
- Build artifacts are in the build/ directory
- Change board with -b parameter and application path as needed

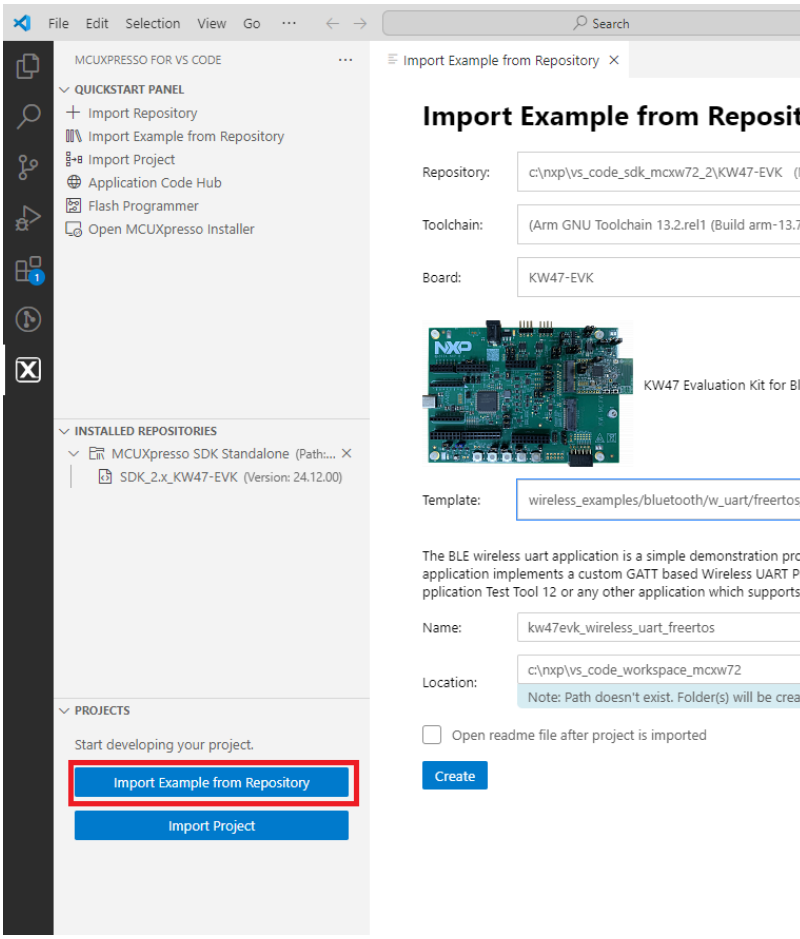
Parent topic: *Building the binaries*

Building and flashing the BLE software demo applications using Visual Studio Code



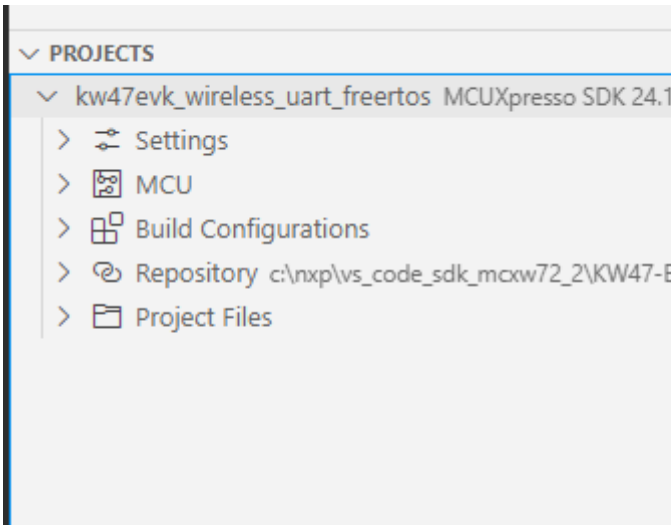
To build and flash the BLE software demo applications using Visual Studio Code, follow the steps listed below:

1. Open Visual Studio Code and open the MCUXpresso for Visual Studio Code extension as shown in the figure below.



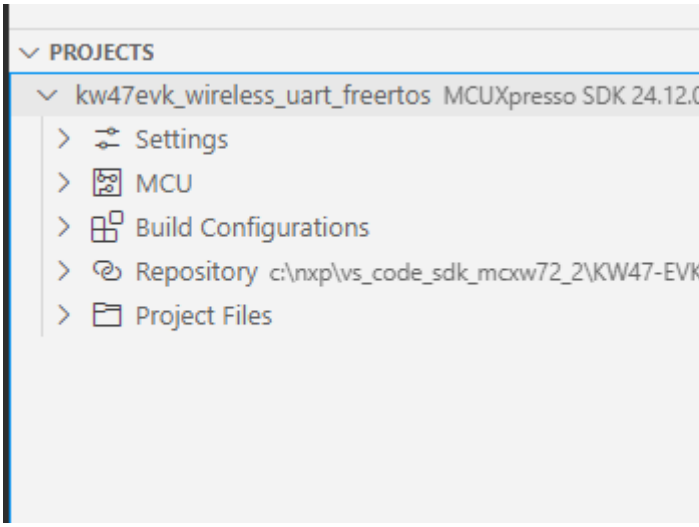
MCUXpresso for Visual Studio Code extension

2. Import the SDK package: click "**Import Repository**". Then, choose the "**Local**" option (if the SDK is archived use "**Local archive**"), browse to the path of the SDK you want, and click "**Import**".



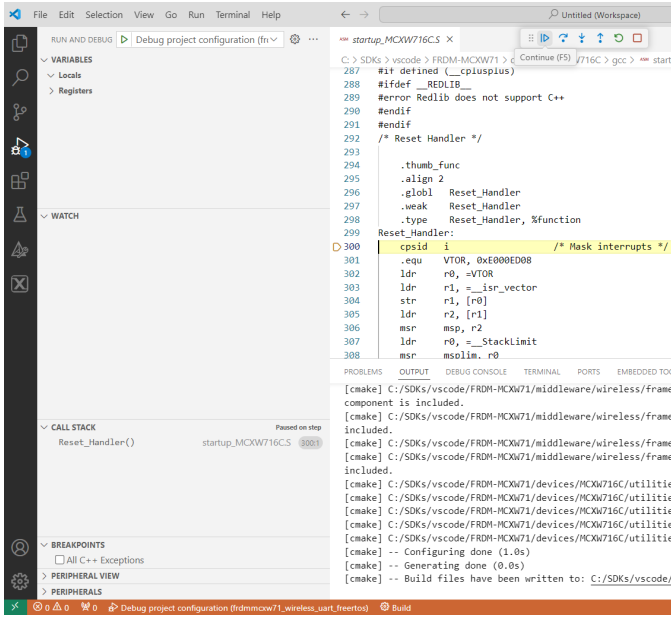
Steps to import the SDK

3. After the SDK is loaded successfully, select the "**Import Example from Repository**" to add an application to your workspace. Choose the repository, toolchain (Arm GNU), board, example you want to add, and the location where the VS Code project would be created. Then click "**Create**".



Steps to import the example application

4. The application now appears in the "**Projects**" tab on the left. Build the application by pressing the "**Build selected**" button.

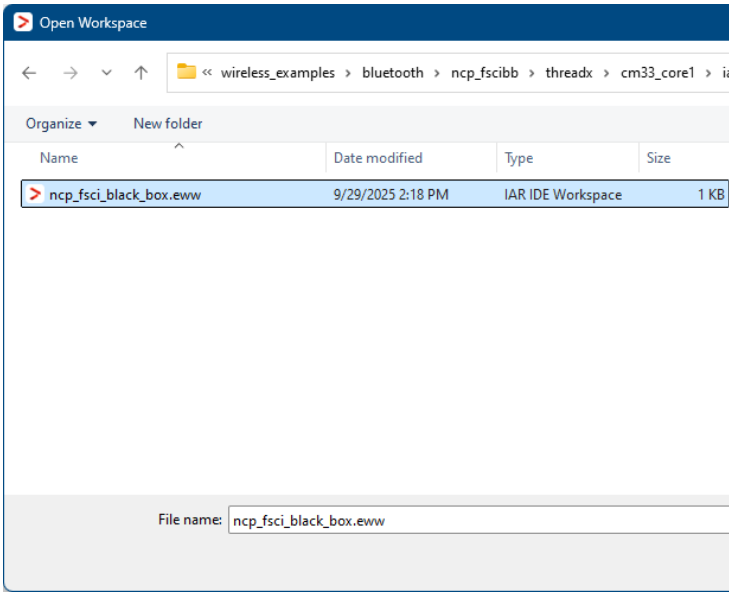


Building the Wireless UART FreeRTOS application

5. After the build is completed successfully, debug the application by clicking the "**Debug**" button.

Debug the Wireless UART FreeRTOS application

6. Press the run (“**Continue**”) button twice to run the application on the board.



Running the Wireless UART FreeRTOS application

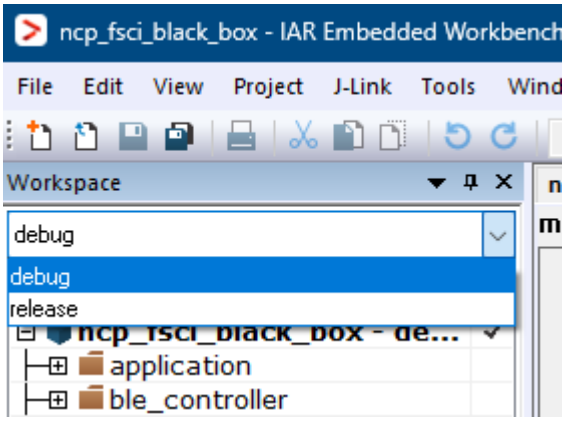
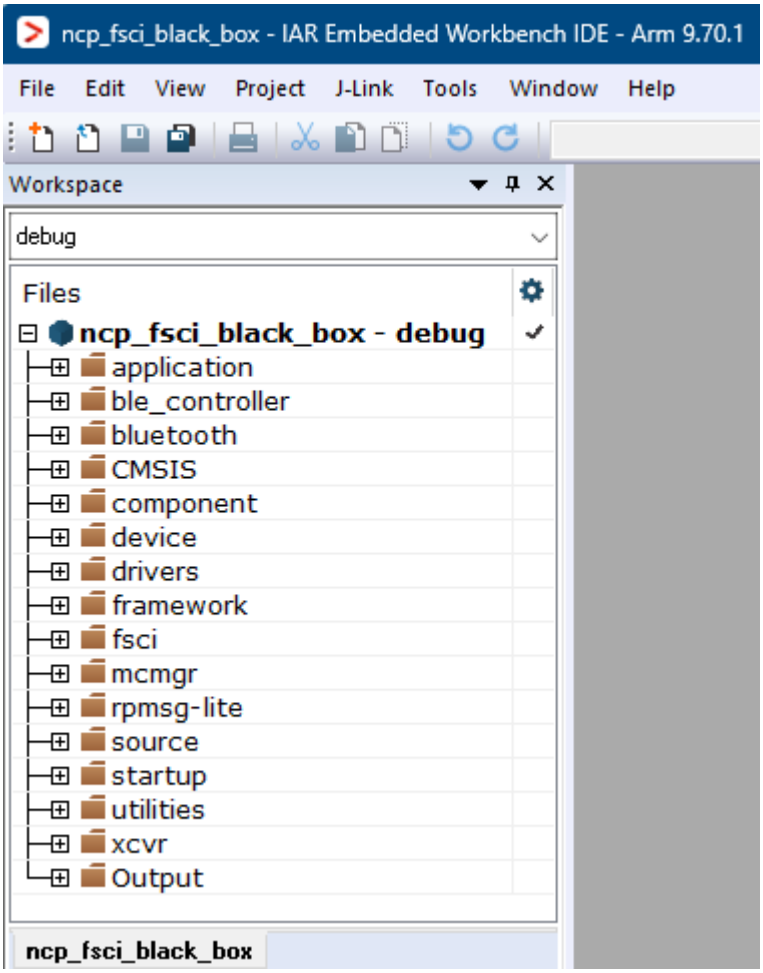
Building and flashing the BLE Extended NBU software demo applications using IAR Embedded Workbench



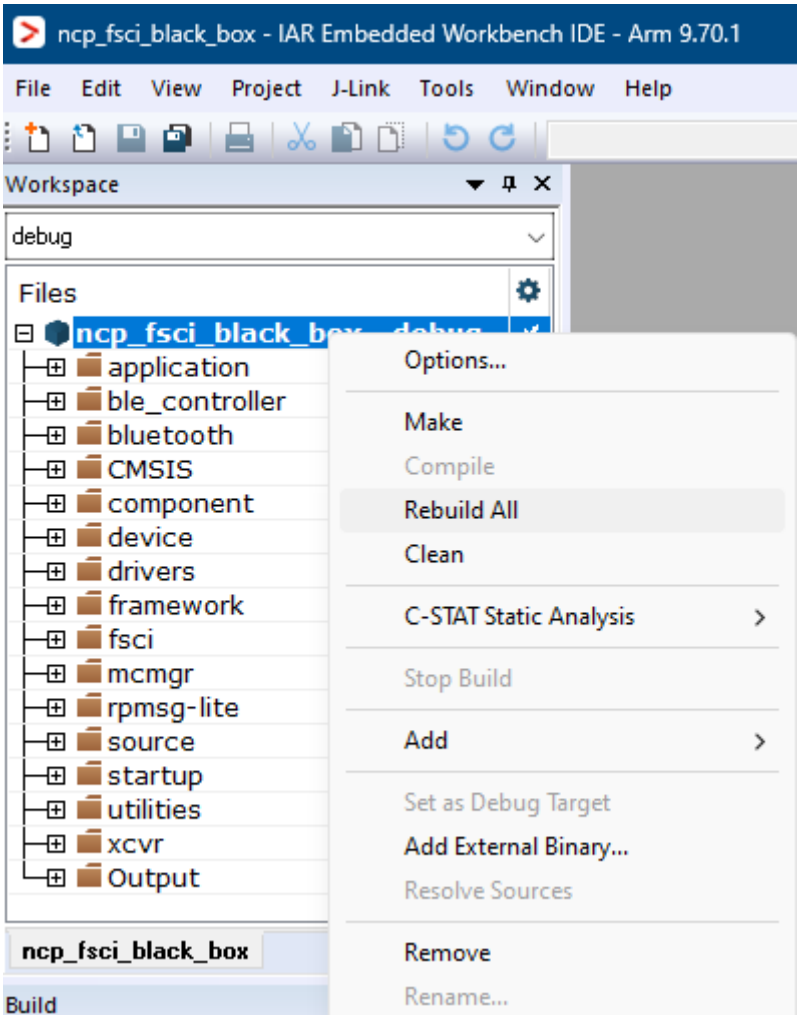
Use the following steps in order to build and flash the BLE software demo applications using the IAR Embedded Workbench:

1. First unpack the contents of the archive to a folder on the local disk. Then, navigate to the resulting location starting from the SDK root directory.
2. Open the IAR workspace file (*.eww file format) highlighted file in the figure below.

NCP FSCI Blackbox IAR demo project location



3. Choose between Debug and Release configurations in the drop-down selector above the project tree in the workspace.

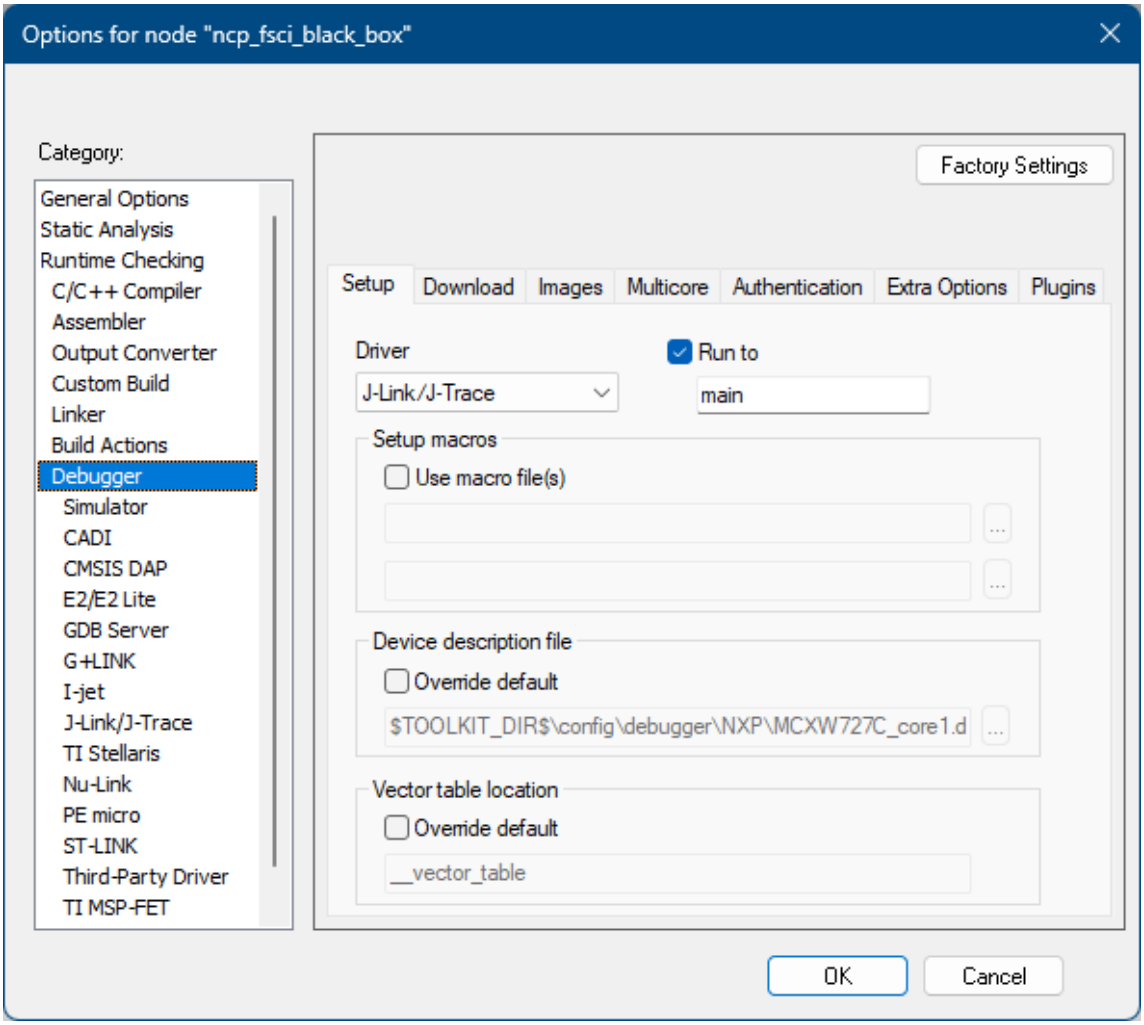


Select the desired configuration (Debug or Release)

The figure below shows the NCP FSCI Blackbox - IAR workspace.

NCP FSCI Blackbox - IAR workspace

4. Build the NCP FSCI Blackbox project using the options shown in the figure.

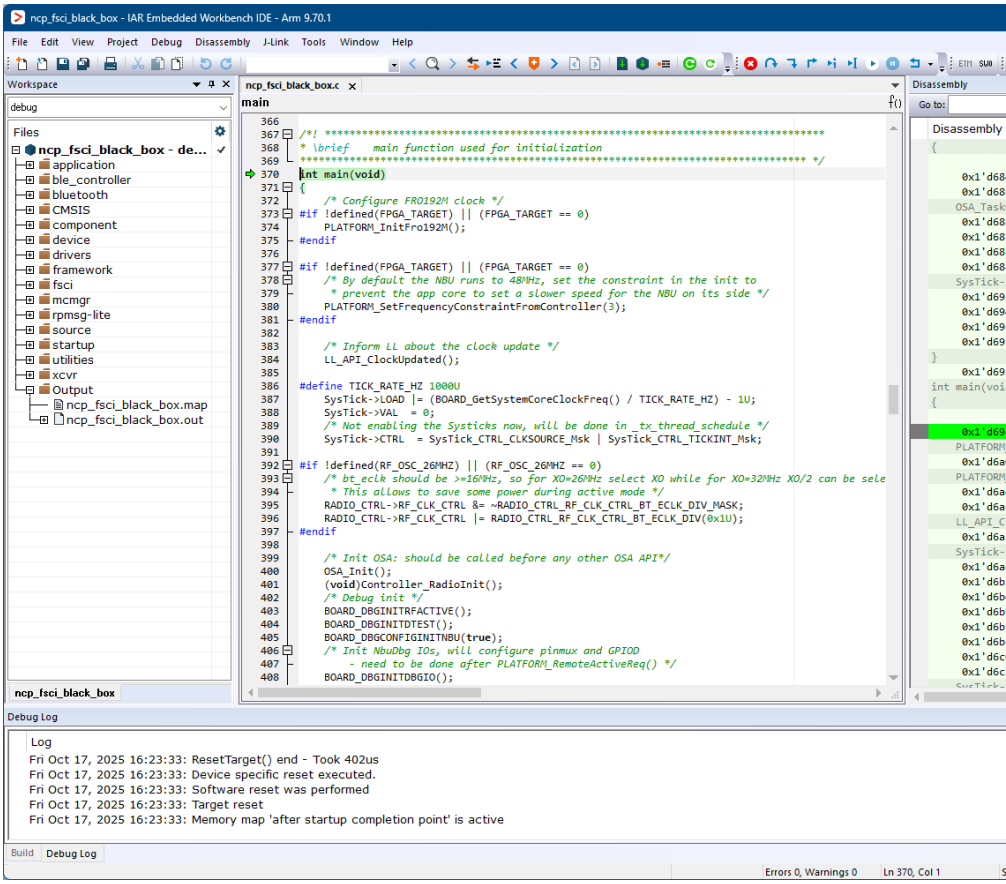


Build NCP FSCI Blackbox application

5. Make the appropriate debugger settings in the project options window, as seen in the next figure.

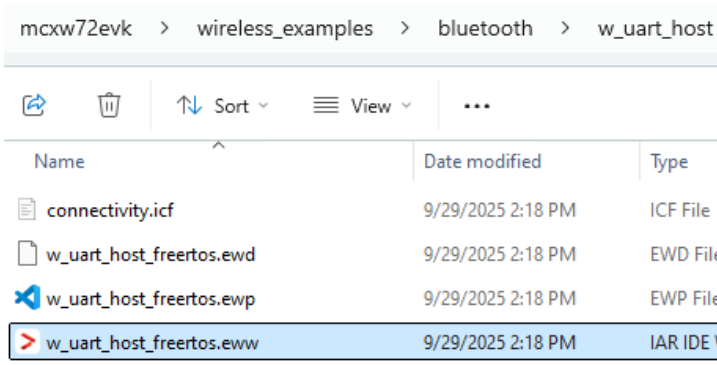
   Go to: **Project > Options (Alt+F7) > Debugger > Setup (tab) > Driver > J-Link/J-Trace**

   Debugger Settings for the NCP FSCI Blackbox project

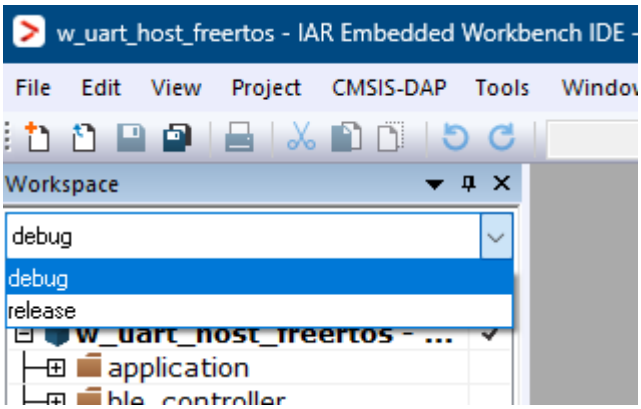


6. Click the "**Download and Debug**" button (or **CTRL+D**) to flash the executable onto the board.

Download and Debug the NCP FSCI Blackbox application



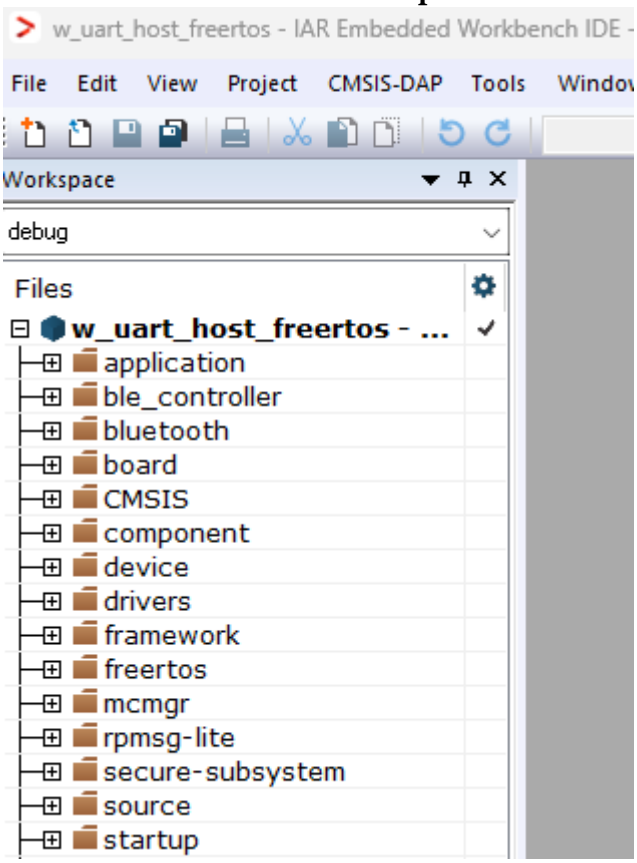
7. Press **Go (F5)**. At this moment, the board starts running the application.



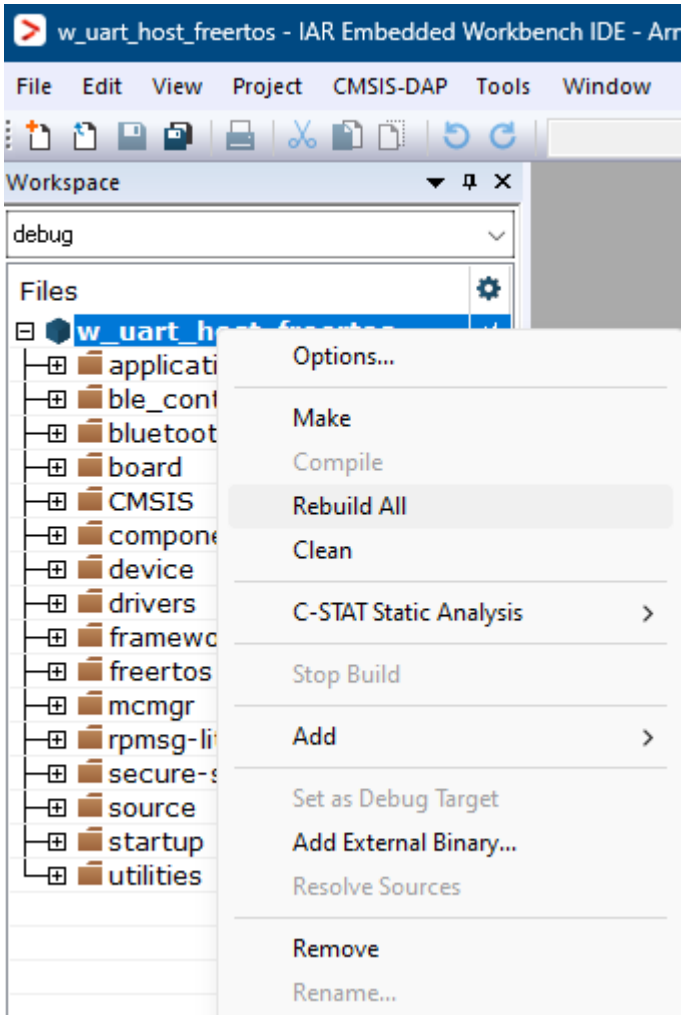
Running the code on IAR

8. Open the Core0 IAR workspace file (*.eww file format) highlighted file in the figure below.

Wireless UART Host IAR demo project location



9. Choose between Debug and Release configurations in the drop-down selector above the project tree in the workspace.

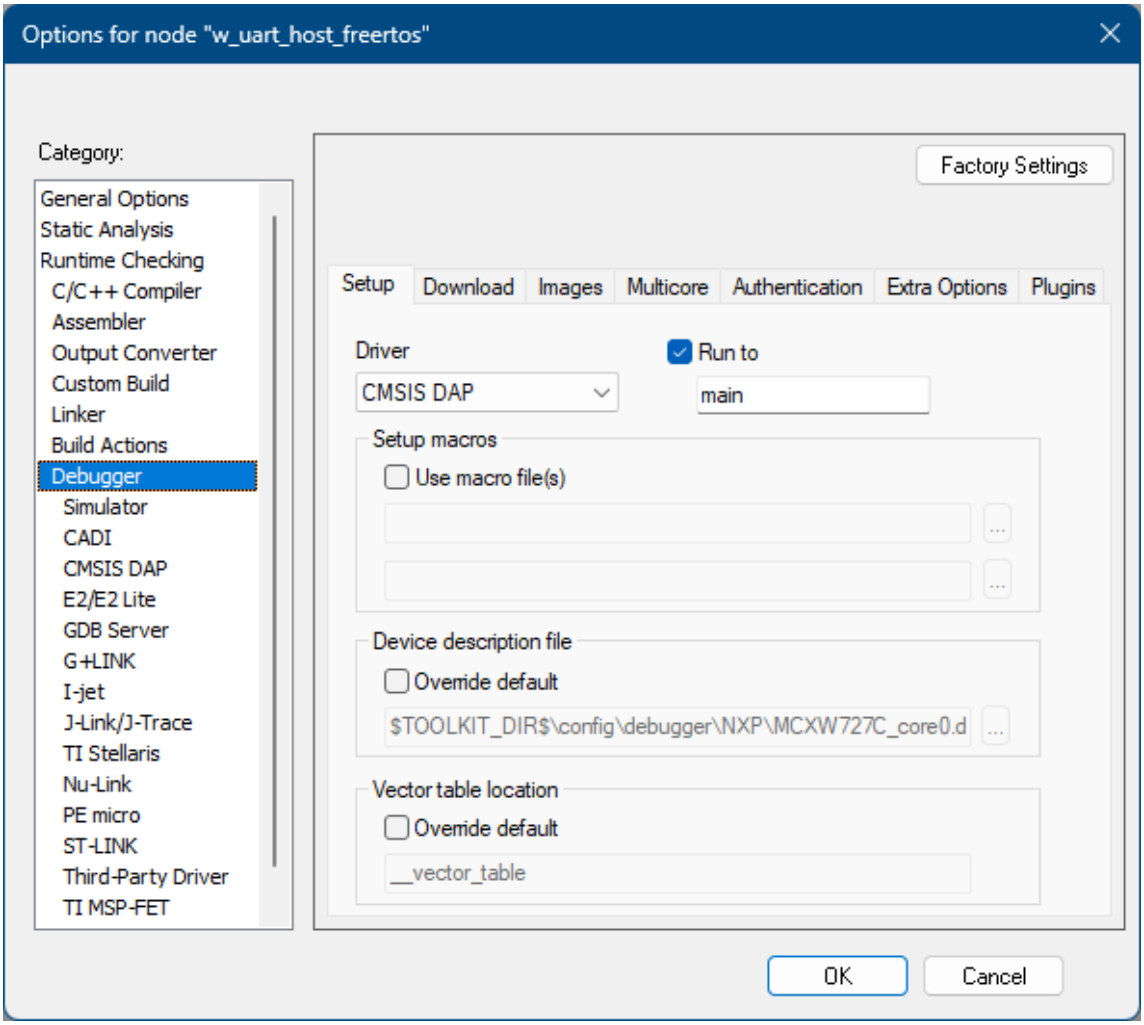


Select the desired configuration (Debug or Release)

The figure below shows the Wireless Uart Host - IAR workspace.

Wireless Uart Host - IAR workspace

10. Build the Wireless Uart Host project using the options shown in the figure.

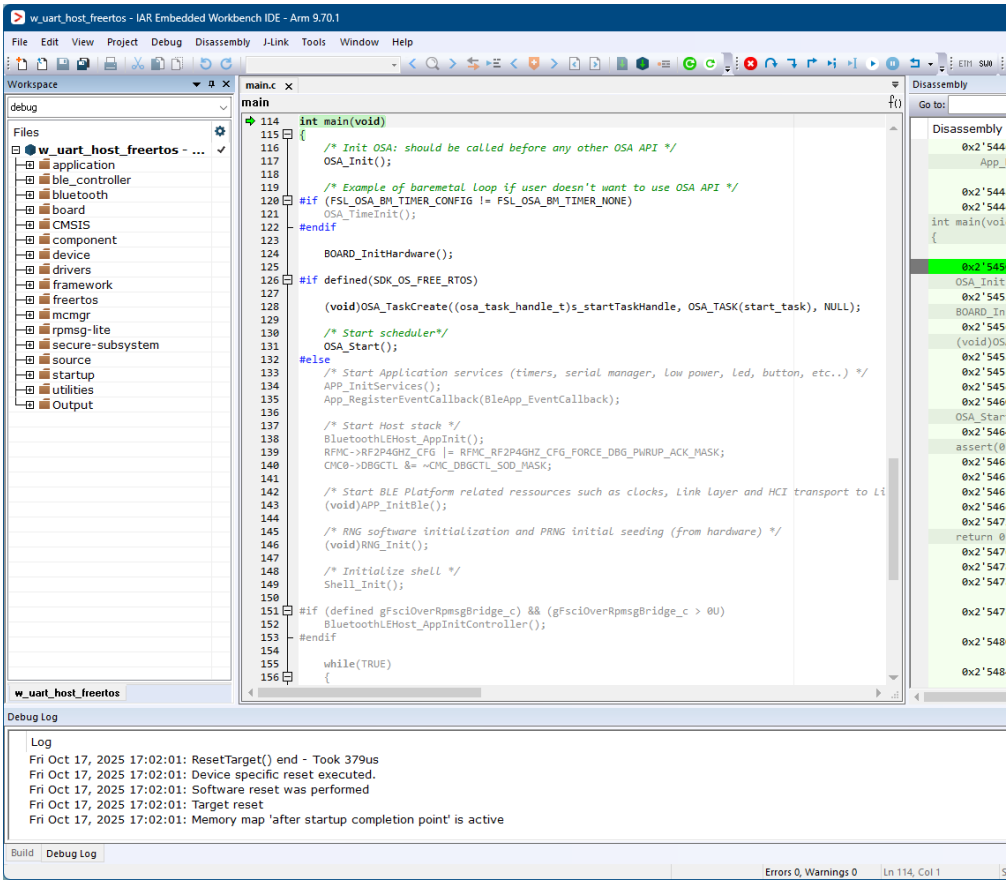


Build Wireless Uart Host application

11. Make the appropriate debugger settings in the project options window, as seen in the next figure.

    Go to: **Project** > **Options (Alt+F7)** > **Debugger** > **Setup (tab)** > **Driver** > **J-Link/J-Trace**

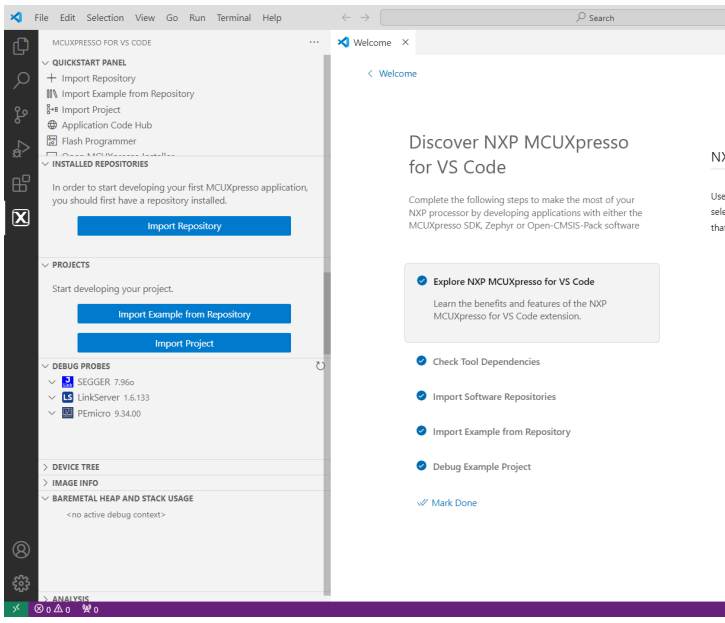
    Debugger Settings for the Wireless Uart Host project



12. Click the "**Download and Debug**" button (or **CTRL+D**) to flash the executable onto the board.

    Download and Debug the Wireless Uart Host application

13. Press **Go (F5)**. At this moment, the board starts running the application.

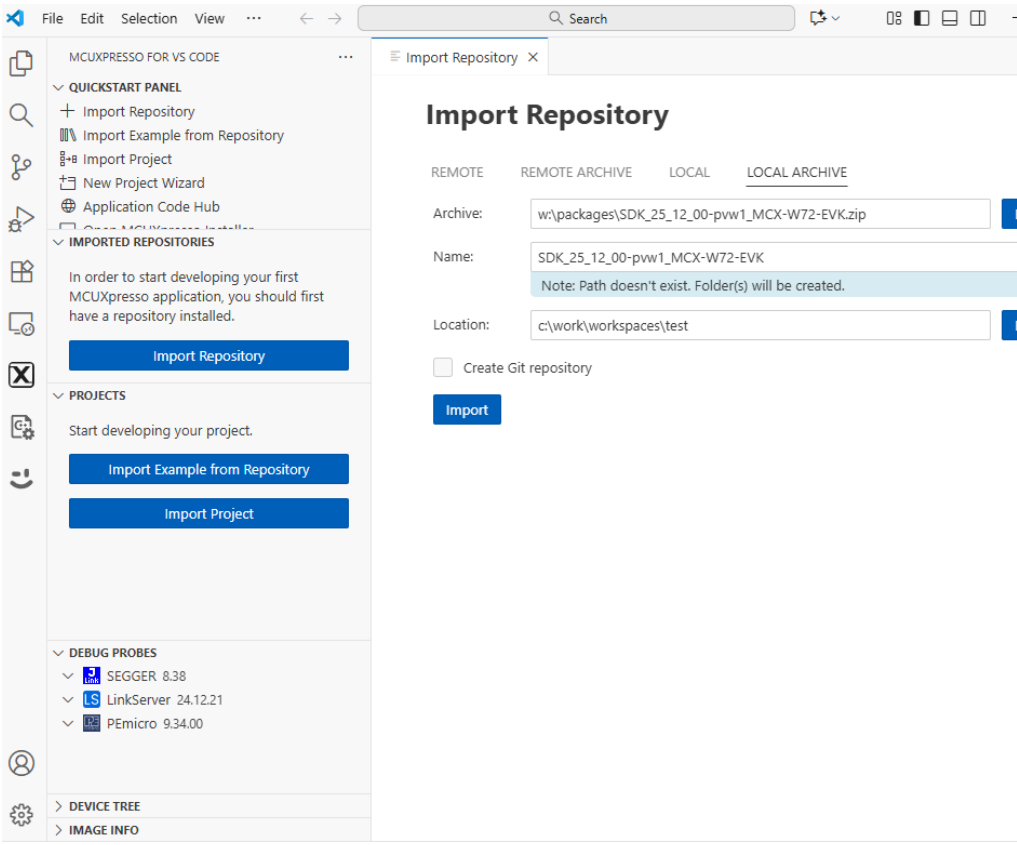


Running the code on IAR

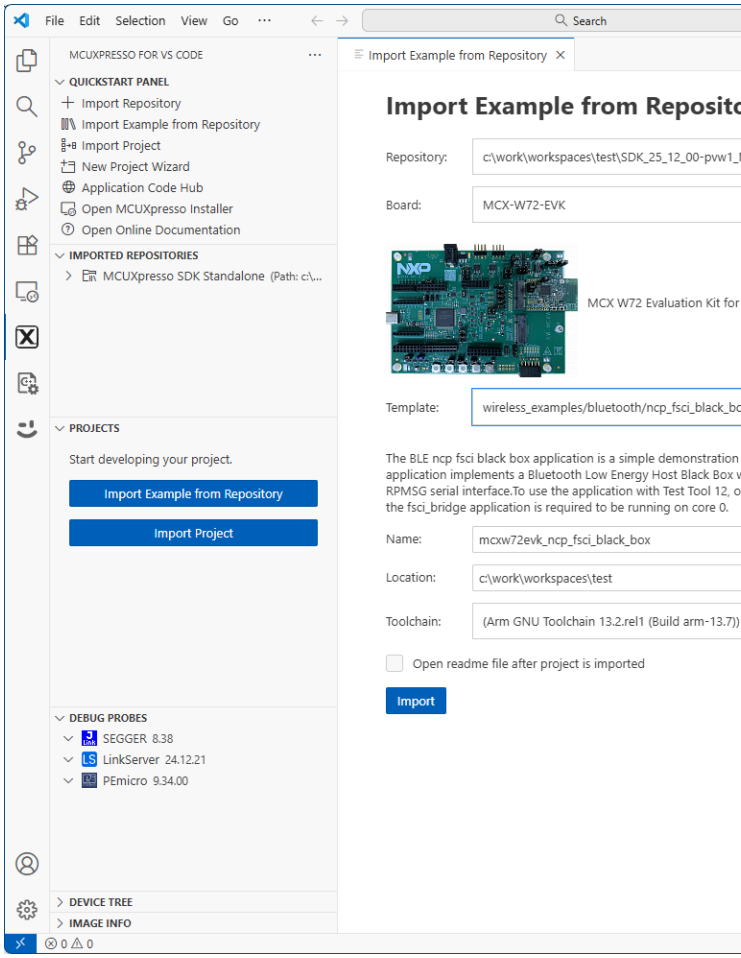
Parent topic:*Building the binaries*

Building and flashing the BLE Extended NBU software demo applications using Visual Studio Code

To build and flash the BLE software demo applications using Visual Studio Code, follow the steps listed below:



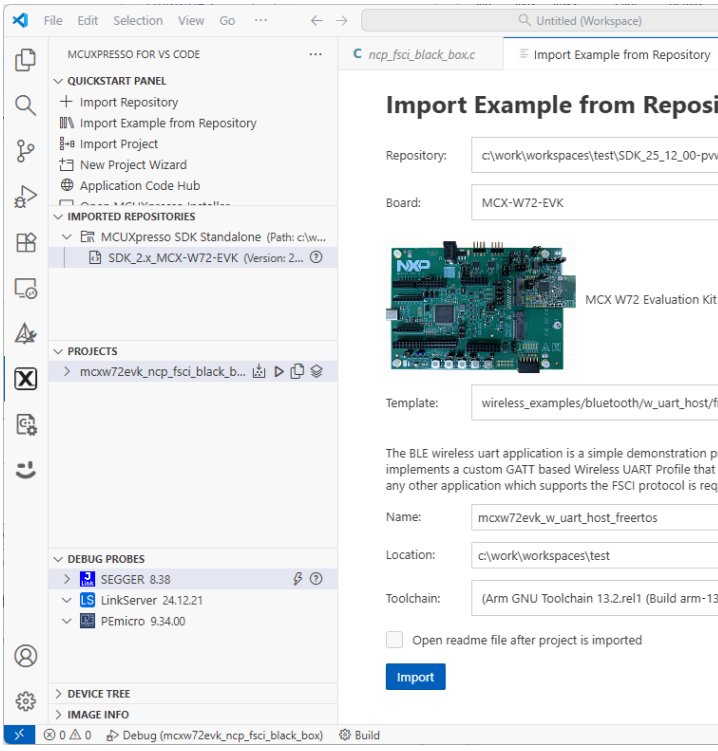
1. Open Visual Studio Code and open the MCUXpresso for Visual Studio Code extension as shown in the figure below.



MCUXpresso for Visual Studio Code extension

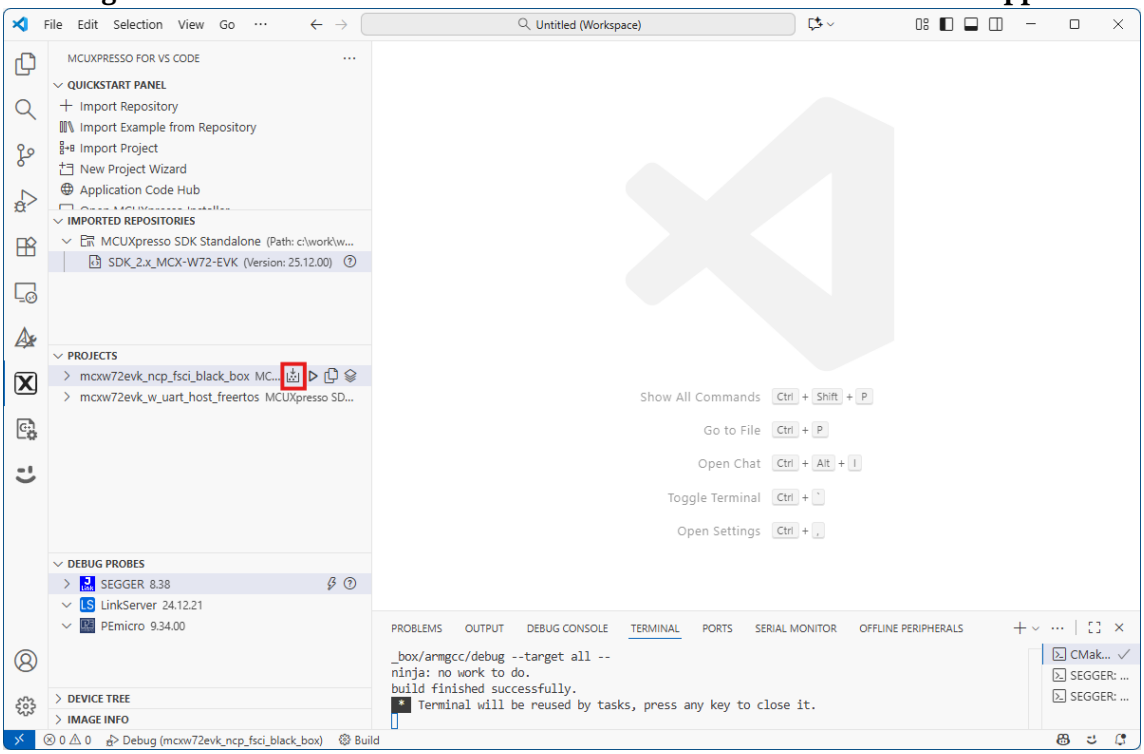
2. Import the SDK package: click “**Import Repository**”. Then, choose the “**Local**” option (if the SDK is archived use “**Local archive**”), browse to the path of the SDK you want, and click “**Import**”.

Steps to import the SDK

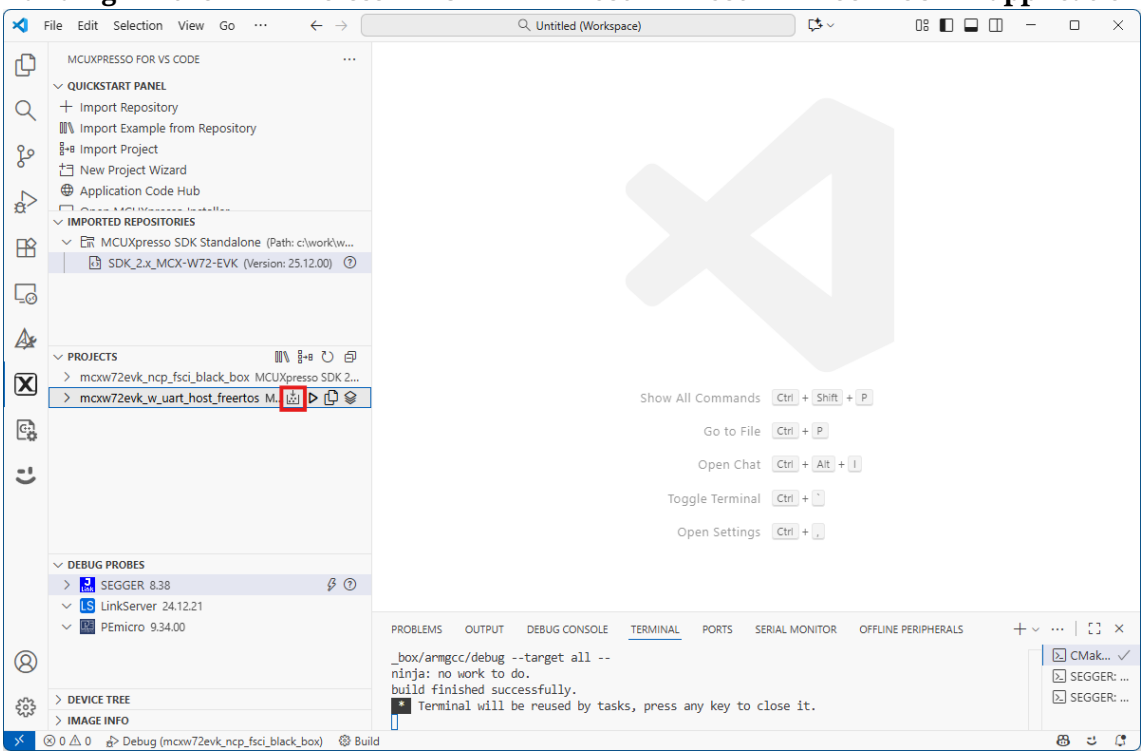


3. Import NCP(Core1) application: After the SDK is loaded successfully, select the “**Import Example from Repository**” to add an application to your workspace. Choose the repository, toolchain (Arm GNU), board, example you want to add, and the location where the VS Code project would be created. Then click “**Import**”.

Steps to import the NCP example application



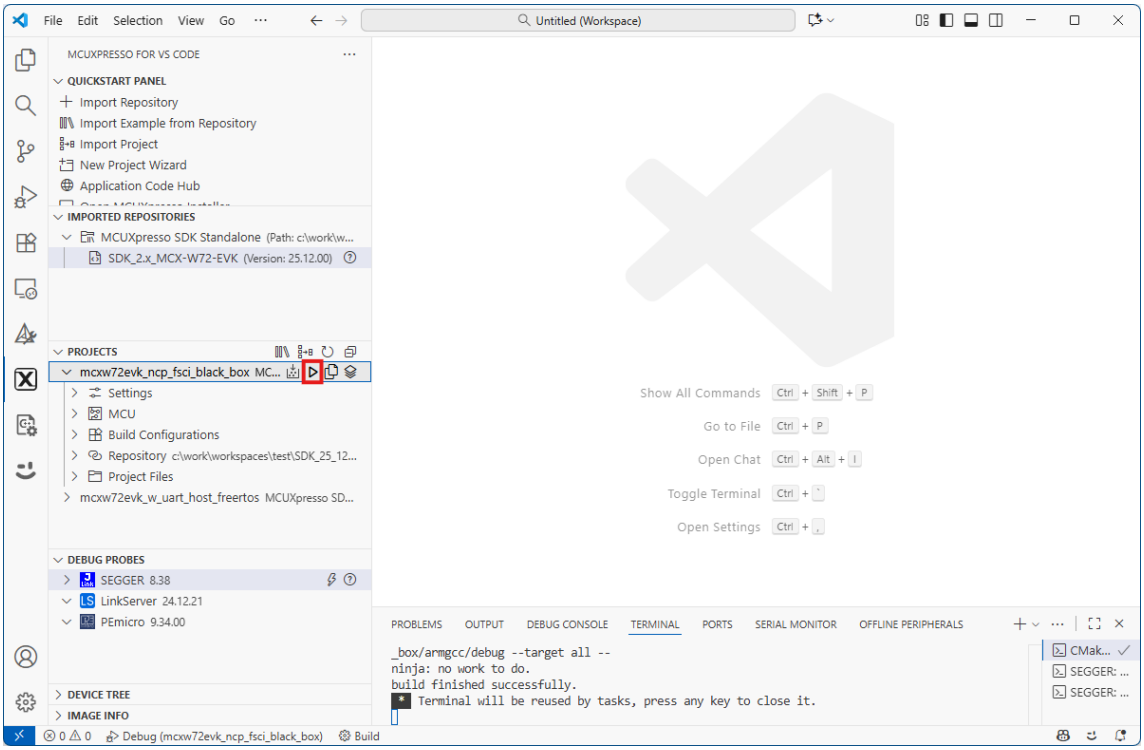
4. Import Core0 application: After the SDK is loaded successfully, select the "**Import Example from Repository**" to add an application to your workspace. Choose the repository, toolchain (Arm GNU), board, example you want to add, and the location where the VS Code project would be created. Then click "**Import**".



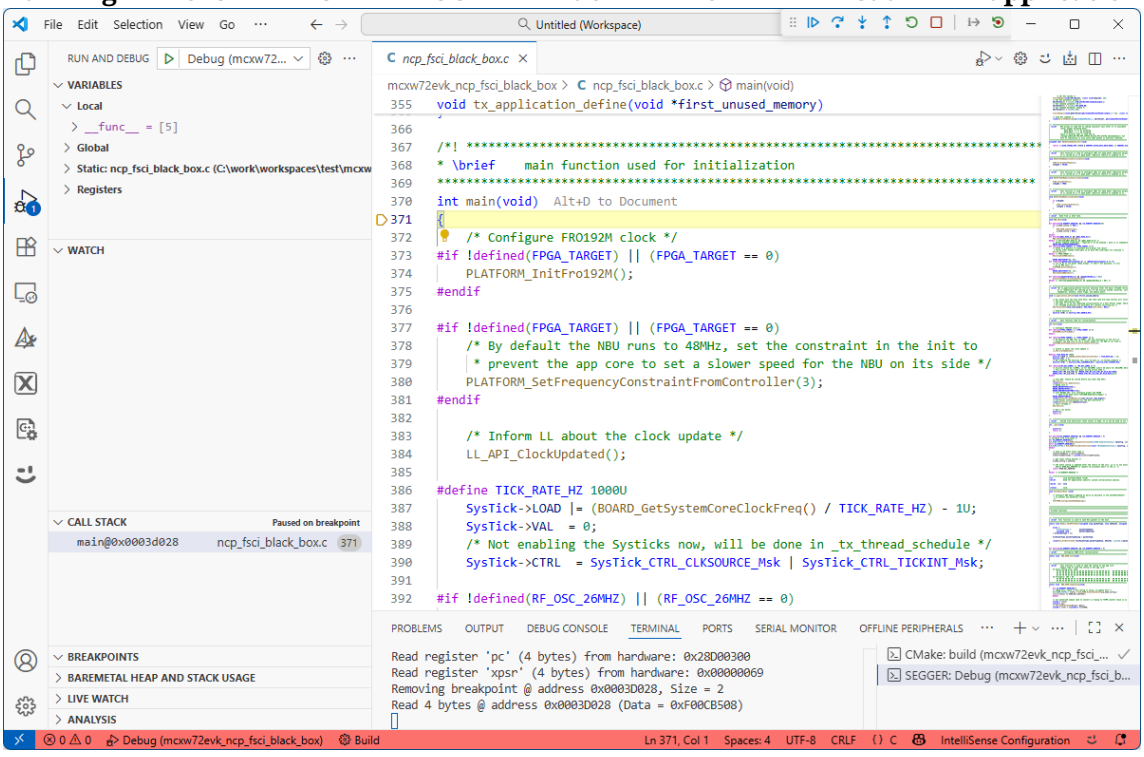
Steps to import the Core0 example application

5. Both Extended NBU applications now appears in the "**Projects**" tab on the left. Build both applications by pressing the "**Build selected**" button on each.

Building the NCP FSCI Black Box ThreadX application

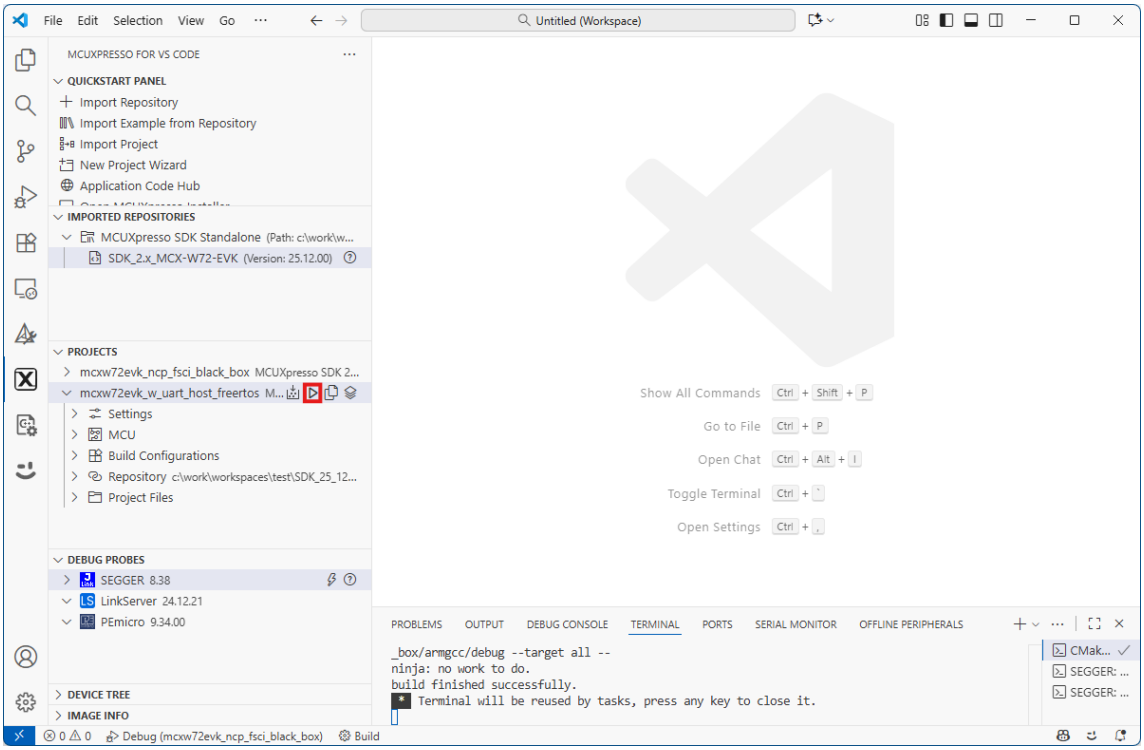


Building the Wireless UART Host Host FreeRTOS application



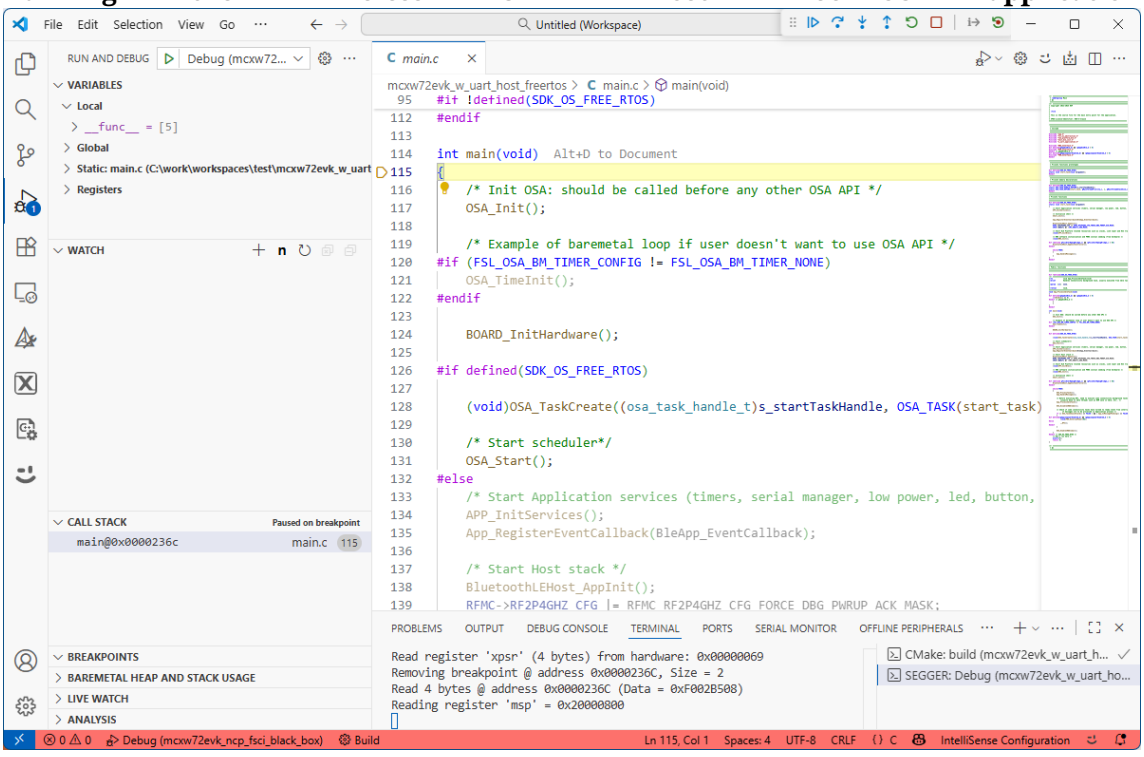
6. After the build is completed successfully, first debug the NBU(Core1) application by clicking the "**Debug**" button.

Debug the NCP FSCI Black Box ThreadX application



7. Press the run (“**Continue**”) button to run the application on the board.

Running the NCP FSCI Black Box ThreadX application



8. After the build is completed successfully and the NBU application was successfully written, debug the Core0 application by clicking the “**Debug**” button.

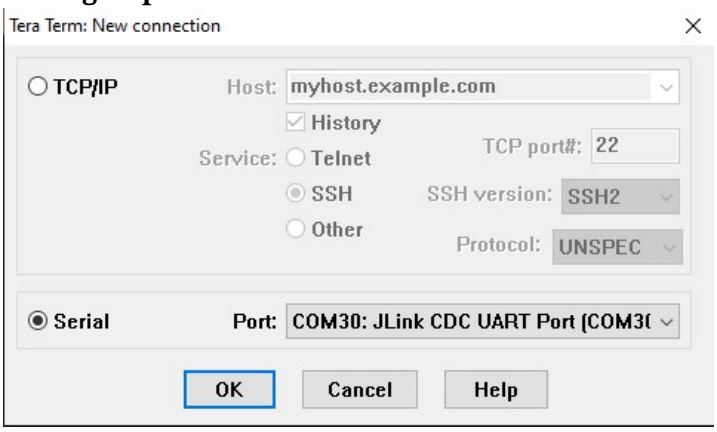
Debug the Wireless UART Host FreeRTOS application

9. Press the run (“**Continue**”) button to run the application on the board.

Running the Wireless UART Host FreeRTOS application

Parent topic:*Building the binaries*

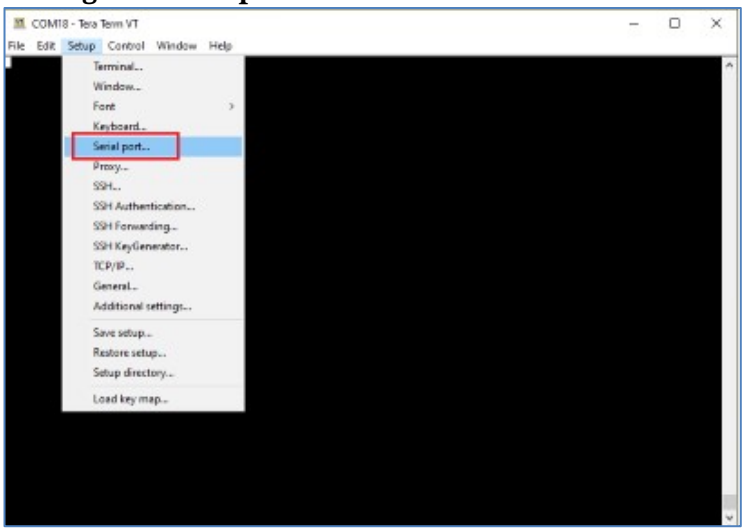
Running the Wireless UART application using NXP IoT Toolbox mobile application



To run the Wireless UART application using NXP IoT Toolbox mobile application, follow the steps as listed below:

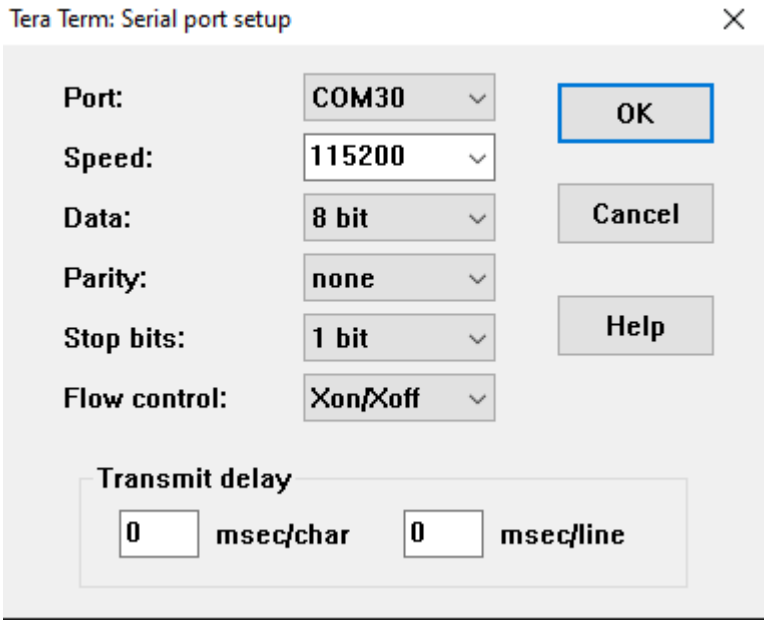
Note: Before working on these steps, ensure to install the latest version of the NXP IoT Toolbox

mobile application from the application store.



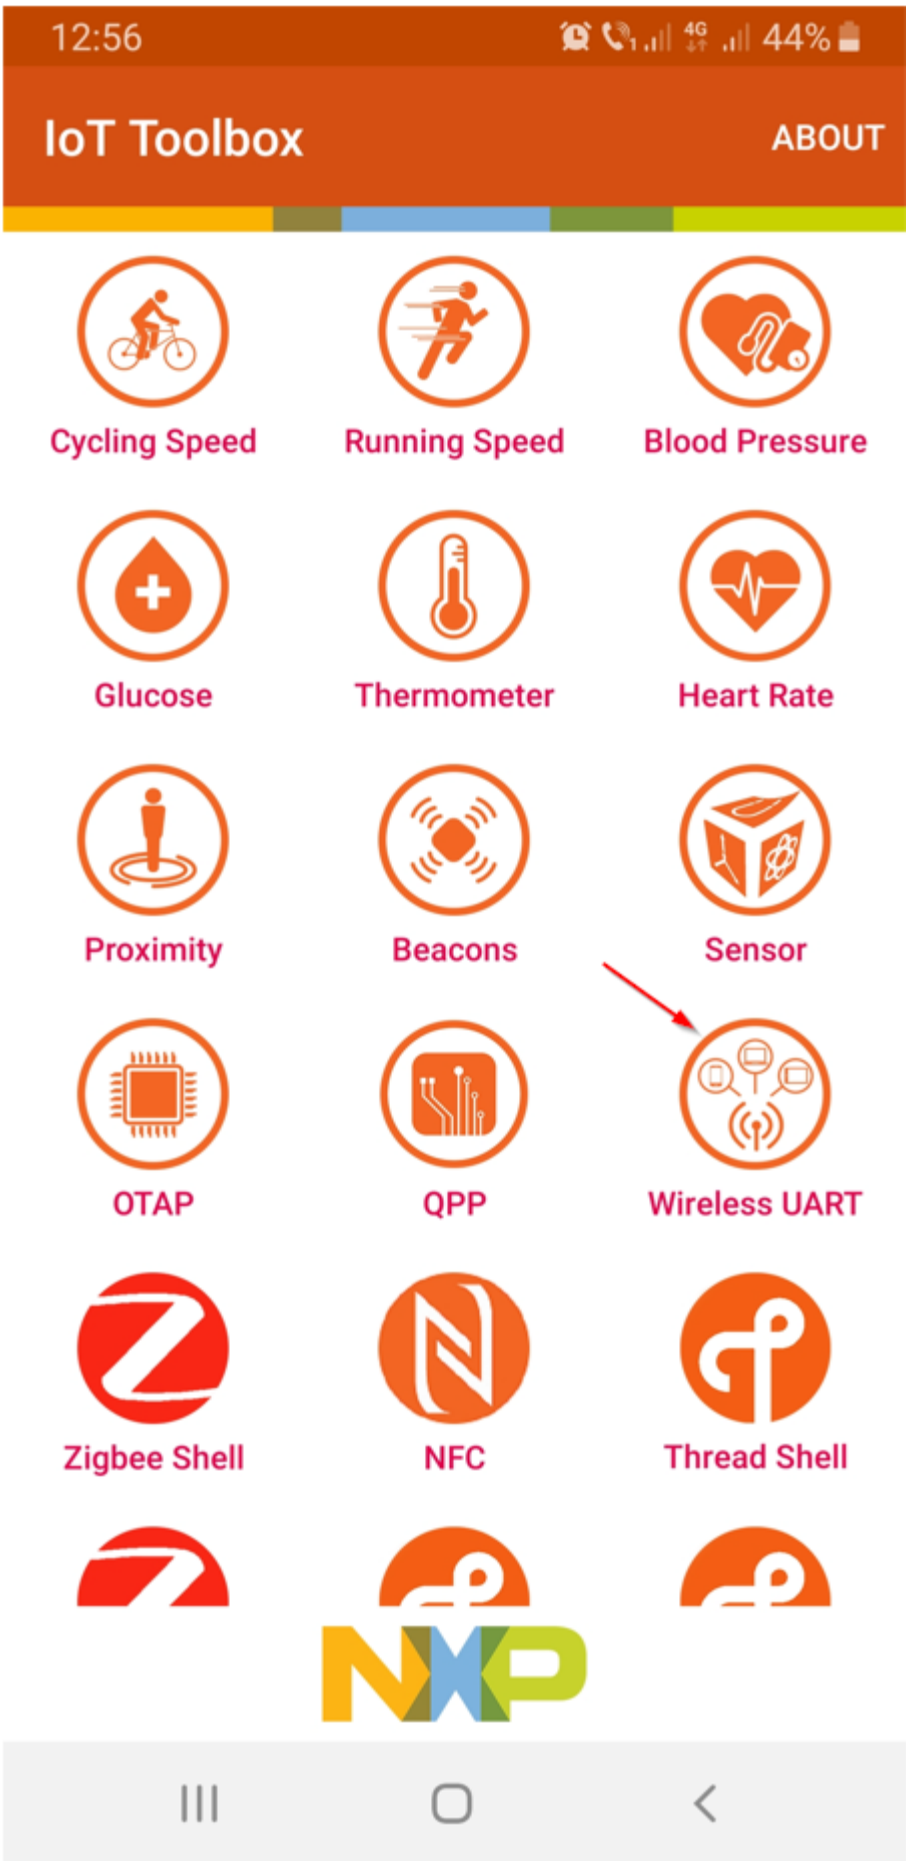
1. Flash the board with the Wireless UART application as previously described.
2. Open Tera Term (or any other Serial Communication software) and choose **Serial**. Then choose the port of your board and click **OK**.

   Setting up a new Tera Term connection for Wireless UART application



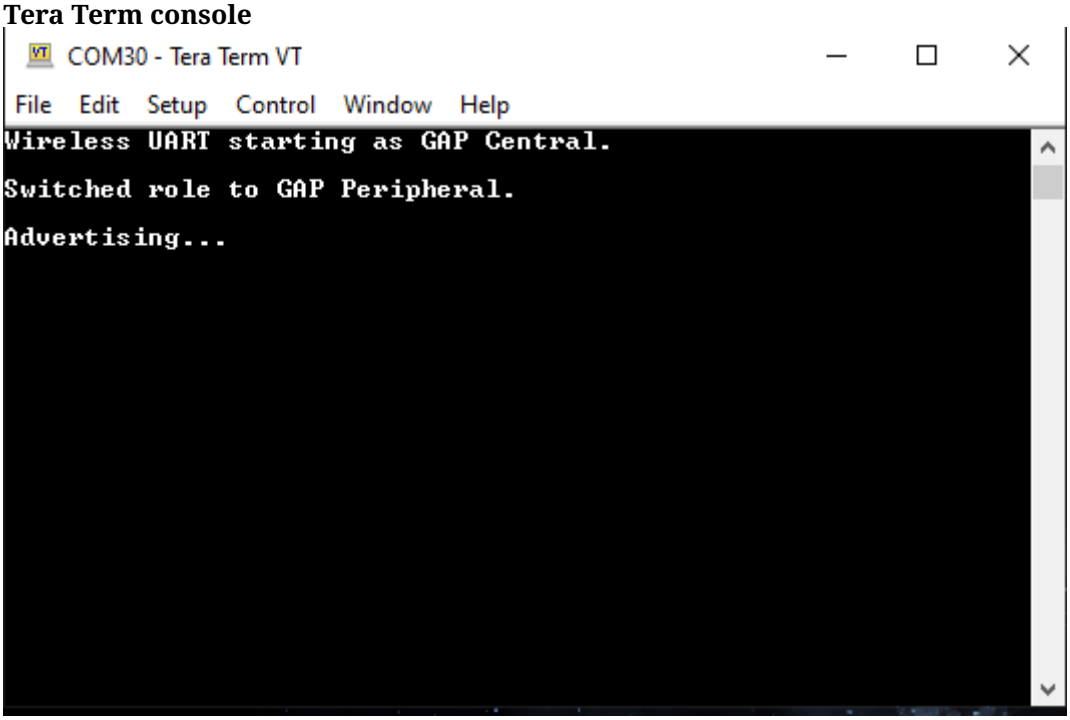
3. Stop running the code on the board. Go to **Setup** >**Serial Port**.

   Setting the serial port



4. Choose the required Speed (baud rate) and Flow Control values. Here, the baud rate should be 115200 and the Flow control mode should be set to **Xon/Xoff**.

   Setting the baud rate



5. Ensure that the Bluetooth device of your phone is enabled.
6. Open the *IoT Toolbox* application and select the ***Wireless UART*** icon.

   NXP IoT Toolbox application

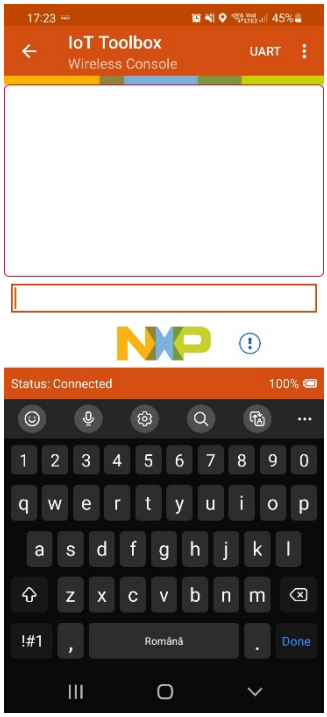
NFC
Thread Shell

7. Now run the application on the board. On this step, the RGB LED blinks white quickly. Press the button **SW3** to switch to Peripheral (Central) mode, then press **SW2** to start Advertising (scanning). The Tera Term terminal shows the message shown in the figure below.

Tera Term console

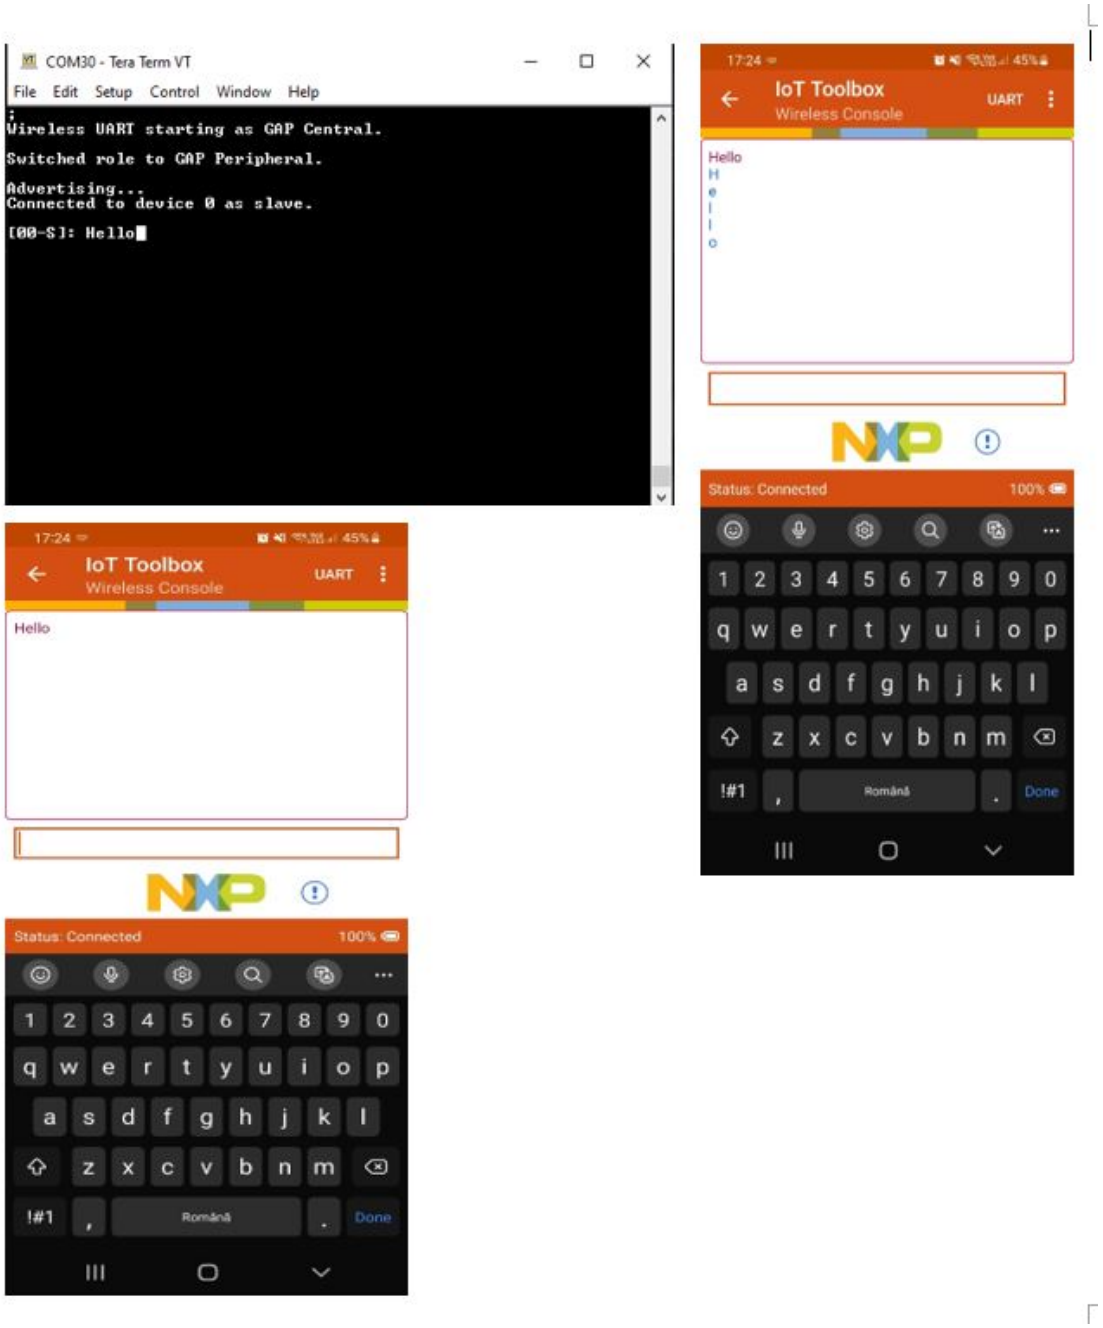


8. The device should become visible for the Wireless UART mobile application.

NXP Wireless UART scanned by IoT toolbox app

9. Select the device that appears in the **Wireless UART** tab to connect to it. After connecting, the mobile application shows the console, as shown below. Users can choose between the Wireless Console and Wireless UART tabs.

   The device should become visible for the Wireless UART mobile application.



Wireless UART working in Connected mode

10. On the IoT Toolbox Wireless application console, the message is introduced in one line and sent to the peer. If Wireless UART mode is used, communication is done character by character. On Tera Term, the message received is displayed. One character at a time can be sent from Tera Term to the peer. When the mobile application receives the character, it displays it.

    The next figure shows the board acting as a peripheral, connected to a phone using IoT Toolbox in Wireless Console and Wireless UART modes.

    Exchanging messages between the phone and Wireless UART Console

Bluetooth Low Energy Demo Applications User Guide Introduction

This document describes the Bluetooth Low Energy host stack enablement for NXP development platforms. The document is organized as follows:

- *Bluetooth Low Energy applications* lists the demo applications that can be located in the Software Development Kit (SDK).
- *Hardware configurations* describes the hardware and toolchain requirements.
- *Building and running a Bluetooth LE example application* describes the general requirements for using and testing a Bluetooth Application on a compatible device.
- *Bluetooth LE stack and demo applications* describes the steps and instructions for using the demo applications on your device. It also presents the profiles and services implemented and how to interact with them.
- *References* lists the additional documents that can be referred for more information.
- *Acronyms* lists the acronyms used in this document.

Bluetooth Low Energy applications

The Software Development Package provides a Bluetooth Low Energy v5.3-compliant host stack implementation with a set of GATT-based profiles and services implemented on top. To demonstrate the device functionality, the following demo applications are implemented.

1. ANCS Client
2. Beacon Application
3. Bluetooth LE FSCI Black Box
4. EATT Central
5. EATT Peripheral
6. HCI Black Box
7. HID Host
8. HID Device (Mouse)
9. Low-power Temperature Sensor and Collector
10. Low-power Extended Advertising Central and Peripheral
11. OTAP Clients ATT and L2CAP and OTAP Server
12. Wireless UART demo application
13. Bluetooth LE Shell application
14. Hybrid (Dual-Mode) Bluetooth Low Energy and Generic FSK
15. Wireless UART Host
16. FSCI Bridge
17. NCP FSCI Black Box

Note: Refer to the application notes that are located in the 'documentation' folder.

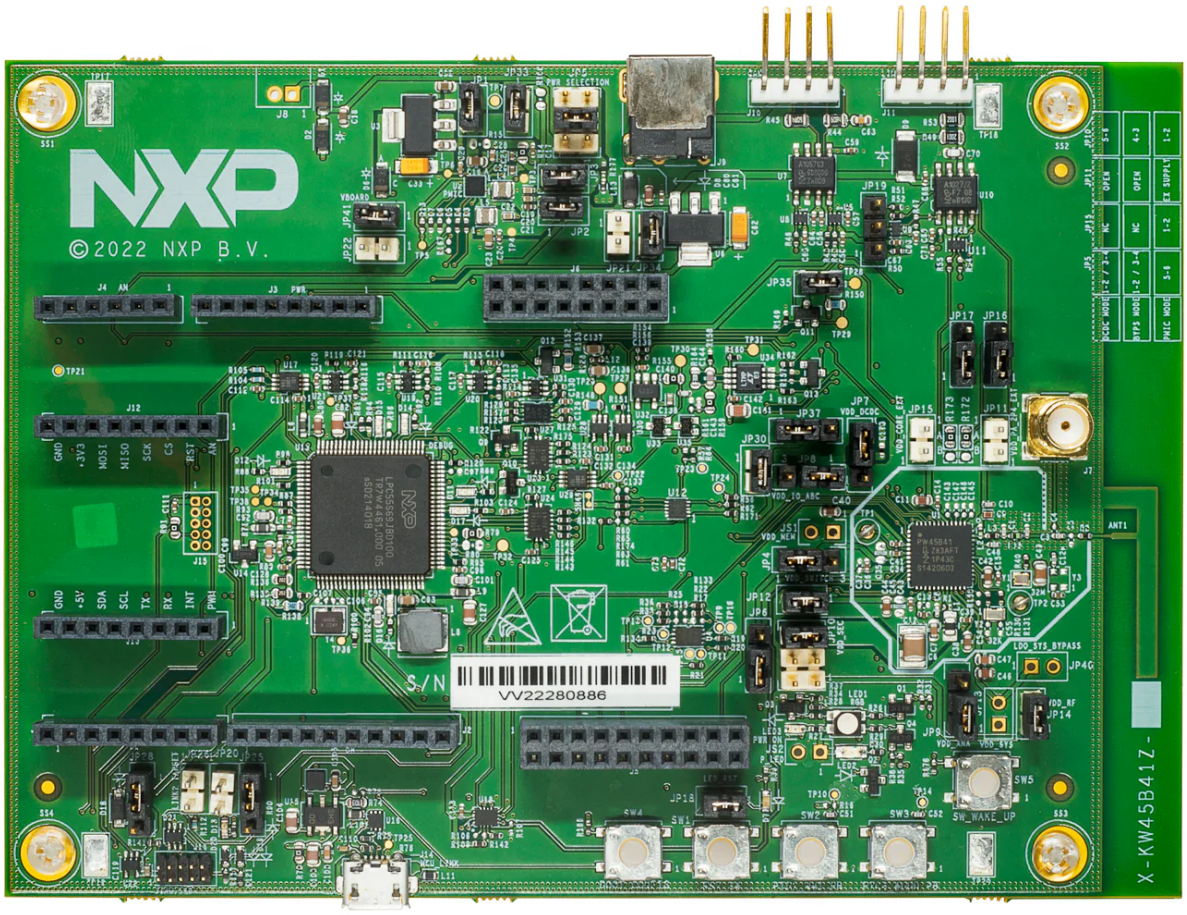
Hardware configurations

Hardware requirements

The NXP Bluetooth LE demo applications run on a selection of the following platforms:

- KW45B41Z-EVK
- KW45B41Z-LOC
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- KW47-LOC
- KW43-LOC
- FRDM-MCXW72
- MCX-W72-EVK
- MCXW72-LOC
- FRDM-MCXW23
- MCXW23-EVK
- FRDM-KW43

Parent topic:*Hardware configurations*



Toolchain requirements

The Bluetooth Low Energy Stack demo applications were compiled and tested with IAR Embedded Workbench for Arm and MCUXpresso. Users must use one of these tools.

Building and running a Bluetooth LE example application

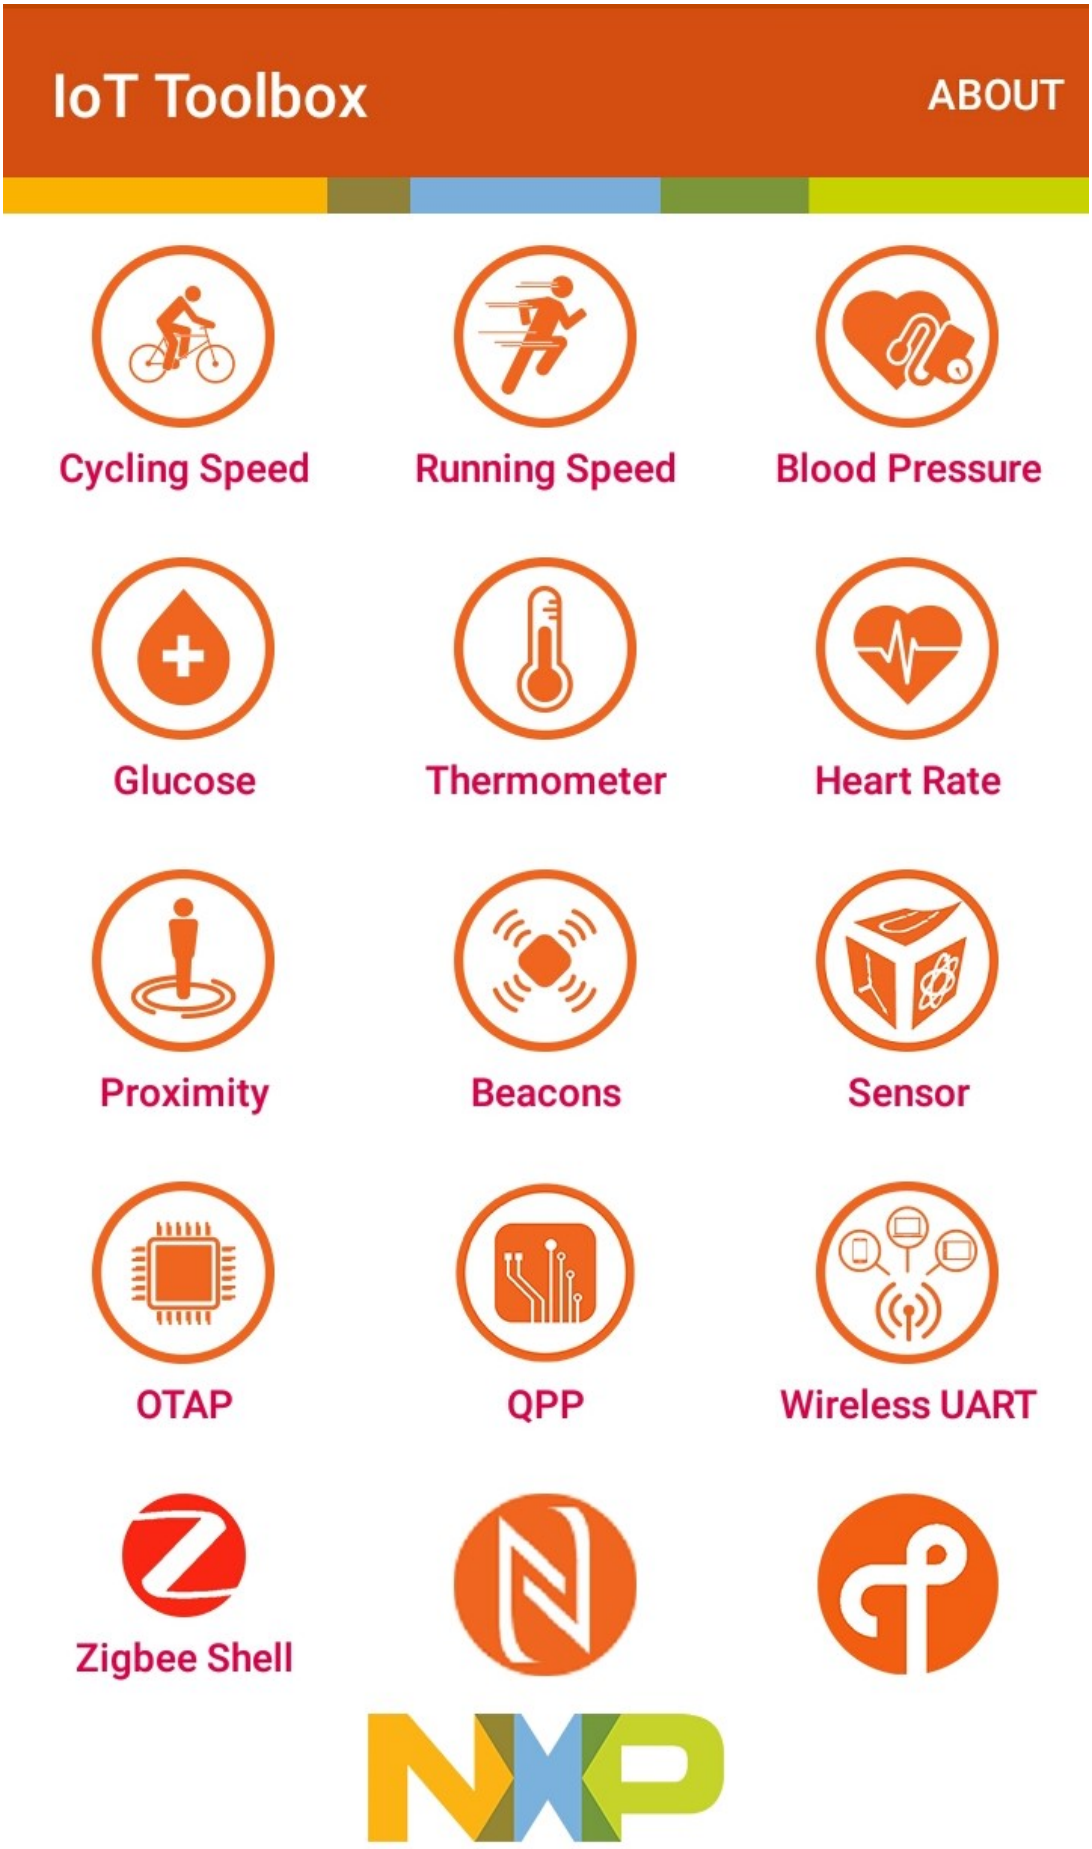
This section presents the general requirements for using and testing a demo application. To open, build, and run any example application on a specific board, refer to the Bluetooth Low Energy Quick Start Guide document for the corresponding board.

User interface

The demo applications that implement the Battery Service expose the current battery level, as measured on the board, through the Battery Level characteristic. The value represents a percentage between 0 and 100. The value can be read from the device from a connected GATT client.

The demo applications that implement the Device Information Service display various information regarding the current software, hardware, and firmware revisions. These values are used as an example and application developers can modify them when developing their product. The values can be read from the device through a connected GATT client.

Parent topic:*Building and running a Bluetooth LE example application*



Security

The examples that enable pairing always generate a default passkey of 999999 that must be entered on the Central device, which is usually a smartphone or tablet.

Parent topic:*Building and running a Bluetooth LE example application*

Testing devices

To demonstrate the profile functionality, most of the scenarios require one of the supported platforms and a Bluetooth Low Energy capable central device. The device is usually a smartphone or a tablet that runs a compatible Bluetooth LE application. The figure below shows the **IoT Toolbox** UI.

IoT Toolbox
ABOUT
Cycling Speed
Running Speed
Blood Pressure

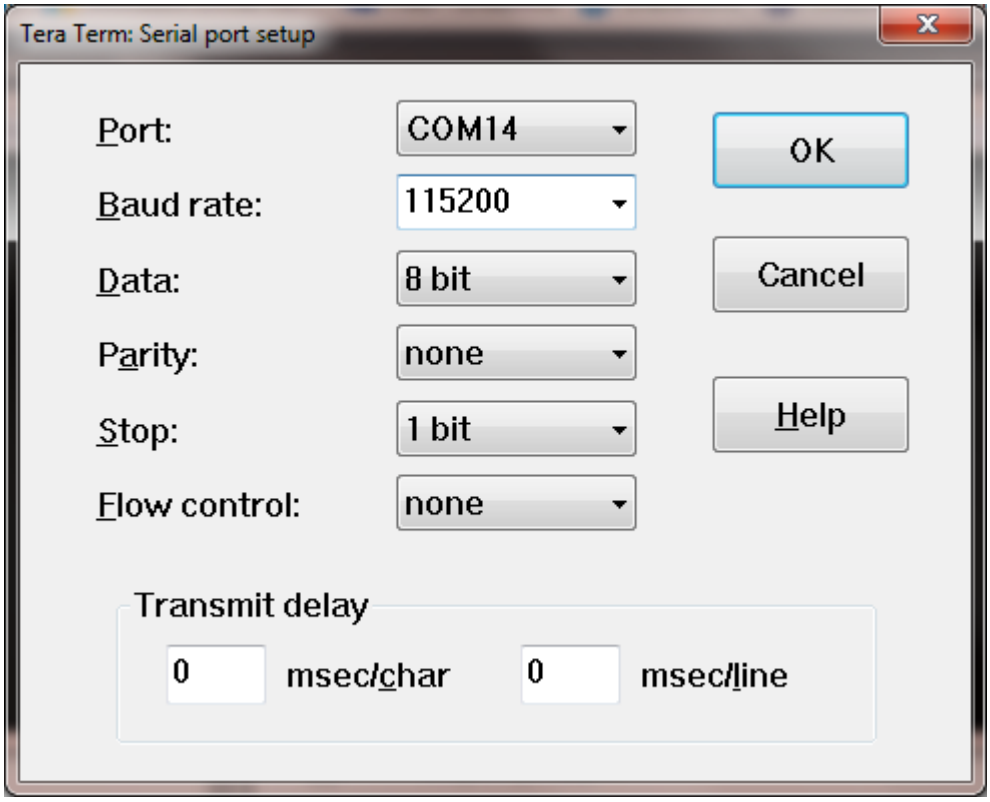
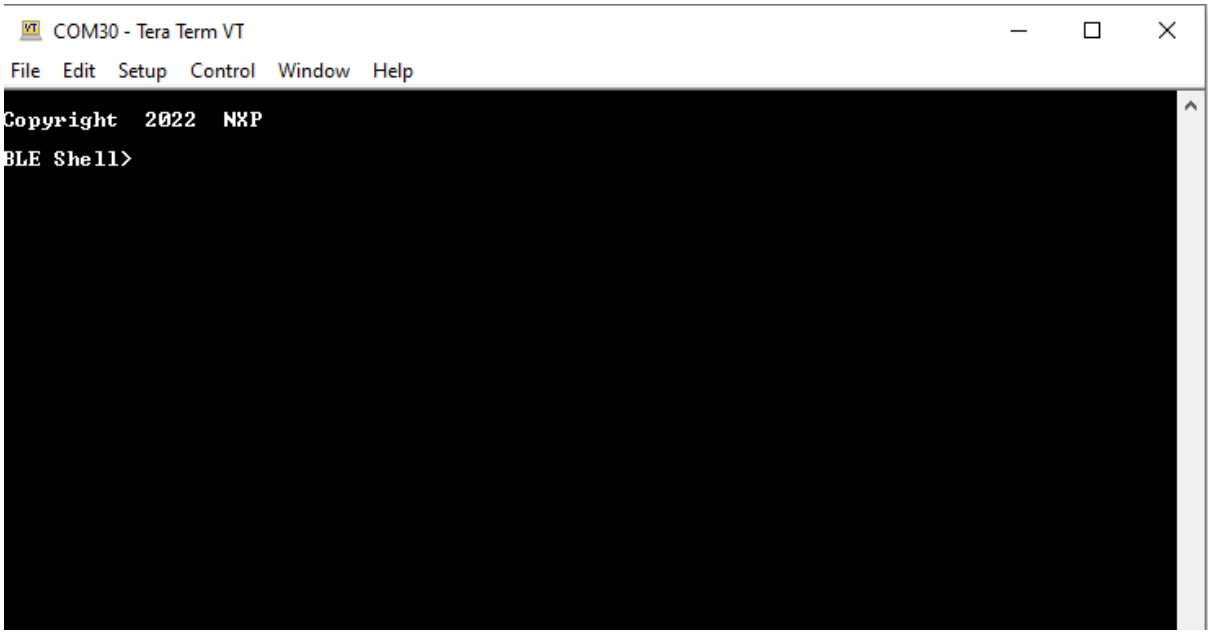
IOT toolbox

The recommended application is the IoT Toolbox, which can be installed on Apple iOS or Android OS handheld devices that support Bluetooth Low Energy. The application can be found on Apple Playstore or on Google Play.



Other demos can be run by using two platforms, one for the peripheral and one for the central role. A few examples of such demos are listed below:

- Low-Power Temperature Sensor and Collector
- Wireless UART
- OTAP Client and Server
- HID Host and Device
- Extended Advertising Central and Peripheral
- EATT Central and Peripheral



To provide feedback and more interaction, some examples use a shell console via the virtual COM port. To access the device, open a serial port terminal and as shown in the figure below. For this example, Tera Term VT and a KW45B41Z-EVK or a FRDM-MCXW71 board can be used. The communication parameters are 115200 and 8N1.

Connect it to the platform with parameters as shown in the figure below .

The start screen is displayed after the board is reset as shown in the figure below .

Parent topic:*Building and running a Bluetooth LE example application*

Time client devices

Some applications implement the Current Time Service. To enable this feature, define the gAppUseTimeService_d parameter in the app_preinclude.h file as 1. If the Time Client is enabled, the device must synchronize with a Time Server to update its internal date/time to the current date/time. If you connect the device to the phone, the Time Client synchronizes with the phone (pairing and bonding must be active).

Parent topic:*Building and running a Bluetooth LE example application*

Bluetooth LE stack and demo applications

ANCS/AMS client (ancs_c)

This section describes the implemented profiles, services, user interactions, and testing methods for the ANCS and AMS Client application.

Implemented profile and services

The ANCS/AMS Client application implements both an ANCS and an AMS Client for the custom ANCS Service and AMS Service available on iOS mobile devices.

Check the documentation available on the iOS website for details about the ANCS or AMS services, their characteristics, and supported features.

The demo application acts as a GAP Peripheral that advertises a service solicitation for the custom ANCS Service, followed by a solicitation to the AMS Service. It also acts as a GATT Client once connected to a device that offers the ANCS/AMS Service. The application offers some services such as the role of GATT Server.

Once connected to a mobile device offering the ANCS/AMS Service, the application displays information about ANCS Notifications received from that device. This information is followed by the AMS track information (Artist, Album, Title, Duration in seconds). The application also displays the possible remote commands that the device state allows (such as Play, Pause, VolumeUp, VolumeDown). The notifications are received via ATT Notifications, for which the ANCS Client must register on the peer ANCS Server. The same must be done for the AMS server. It initially configures the information that it wants to be notified about. The application also retrieves and displays additional information about the received ANCS notifications. For this purpose, it writes commands to specified characteristics on the ANCS/AMS Server and receives responses via ATT Notifications from other characteristics. All information is displayed to the user using a shell available over a serial communications interface.

Accessing the ANCS Service and AMS Service requires Bluetooth LE security to be enabled.

Parent topic:ANCS/AMS client (ancs_c)

Supported platforms

The ANCS/AMS Client application is supported on the following platform:

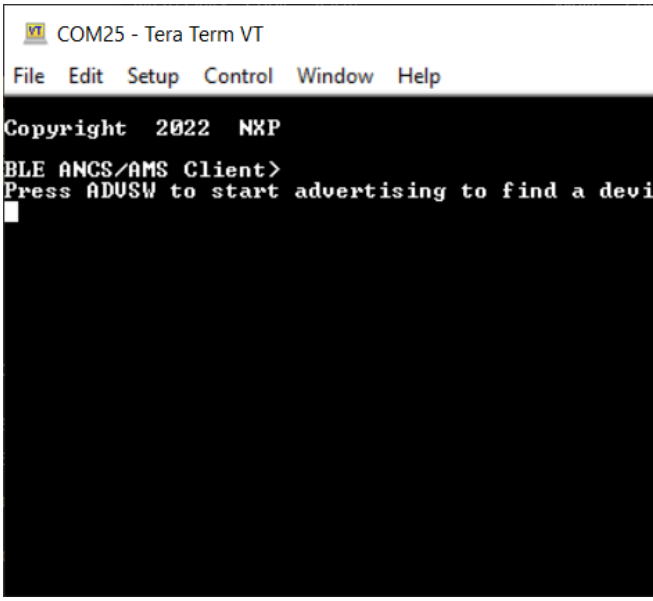
- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK
- FRDM-KW43

Parent topic:ANCS/AMS client (ancs_c)

User interface

After flashing the board, the device is in idle mode (all LEDs flashing). To start advertising, press the **ADVSW** button. When in GAP Discoverable Mode, **CONNLED** is flashing. When the ANCS/AMS Server (Gap Central) connects to the ANCS/AMS Client (GAP Peripheral), **CONNLED** turns solid. To disconnect, hold the **ADVSW** for 2-3 seconds. The ANCS/AMS Client then re-enters the advertising state.

For displaying operating information and ANCS Notifications (AMS information and commands), the demo application uses a shell exposed via a serial communication interface.



Parent topic:ANCS/AMS client (ancs_c)

Switches and pins

Usage

The ANCS/AMS Client demo application is designed to work with a peer mobile device that exposes the ANCS and AMS service. Also, a serial terminal application is required for displaying ANCS Notifications information and AMS commands and information.

1. Open a serial terminal application on the PC and connect it to the serial port corresponding to the board on which the ANCS/AMS Client runs. See the details in Testing devices, “User Interface”. A start screen is displayed immediately after the board is reset. All LEDs must be flashing as shown in the figure below.

Start screen for ANCS/AMS Client demo application

2. Press the **ADVSW** button to start advertising. This instruction is also displayed in the serial terminal as shown in the figure above.
3. The peer device starts scanning for Bluetooth LE devices and connects to the ANCS/AMS Client device that is advertising.
4. Once connected to a peer, the application looks for the ANCS Service and AMS Service and their characteristics. If they are found, the ANCS Client tries to register for receiving notifications and AMS for the tracking data and commands. See Figure.
5. If any security-related ATT errors are encountered, then the application automatically performs Pairing and Bonding and retries the failed ATT operations. Depending on the negotiated pairing method, user interaction might be needed to complete the Pairing. Follow the onscreen instructions provided by both the ANCS/AMS Client and the mobile device. If the ANCS/AMS Client generates a passkey, then the default 999999 passkey is used. See the figure below that shows a ‘Pairing is successful’ message.

Parent topic:ANCS/AMS client (ancs_c)

Parent topic:*Bluetooth LE stack and demo applications*

Beacon

This section presents the user interactions and testing methods for the Beacon application.

Advertising data

The beacons are non-connectable advertising packets that are sent on the three advertising channels. The latter contains the following fields.

- Company Identifier (2 bytes): 0x0025 (NXP ID as defined by the Bluetooth SIG).
- Beacon Identifier (1 byte): 0xBC (Allows identifying an NXP Beacon alongside with Company Identifier).
- UUID (16 bytes): Beacon sensor unique identifier.
- A (2 bytes): Beacon application data.
- B (2 bytes): Beacon application data.
- C (2 bytes): Beacon application data.

- RSSI at 1m (1 byte): Allows distance-based applications.

By default, the UUID value is a random value based on the unique identifier of the board.

Parent topic: Beacon

Supported platforms

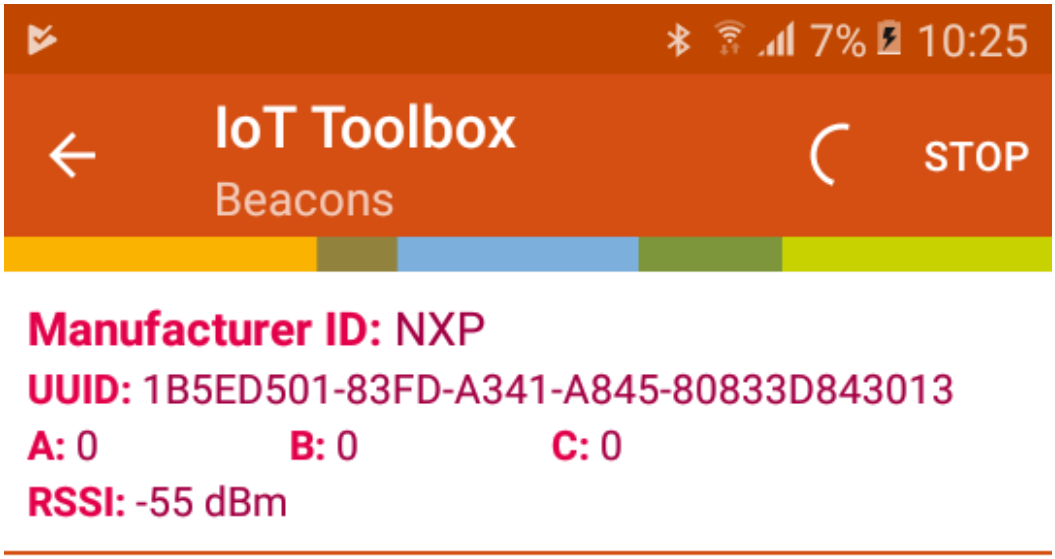
The following platforms support the Beacon application:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK
- FRDM-KW43

Parent topic: Beacon

User interface

After flashing the beacon, the sensor is put in deep sleep (all LEDs are off). To flash the board in case the beacon is put in Deep-sleep mode, press the **ADVSW** or **RESET** button. After this step, any attached debugger loses its connection. The default configuration of the application enables low power, which disables LED support. The user can manually change the configuration and enable LED support, otherwise all subsequent LED behavior references are ignored.



By default, the application uses extended advertising. However, it can be configured to use legacy advertising by setting the $\mathrm{gBeaconAE\_c}$ define to 0. In the legacy configuration, the first press of the advertising switch starts the legacy advertising and the second press stops it.

Parent topic: Beacon

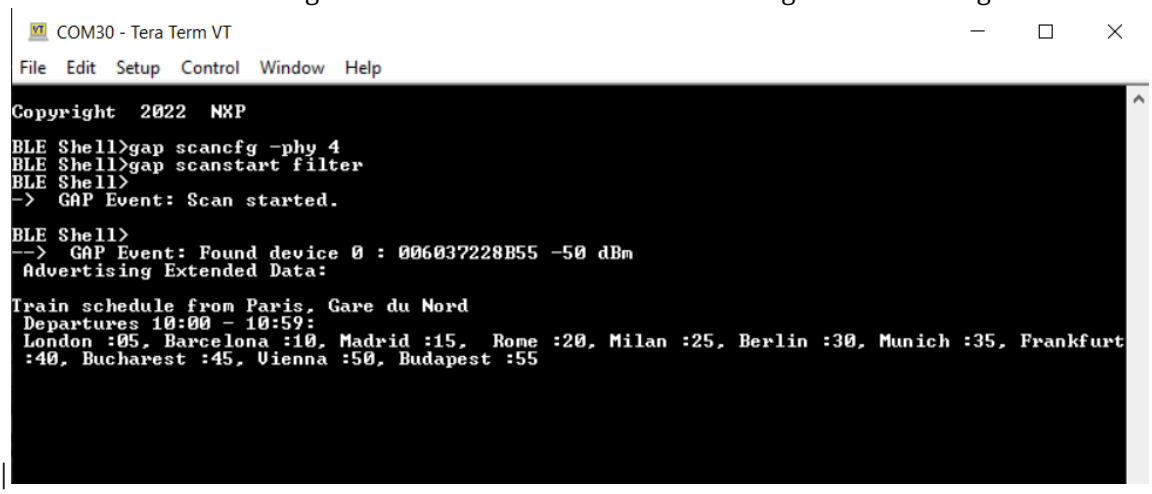
Switches and pins

Usage

The beacon can be tested with any Bluetooth® Smart Ready products available on the market. The IoT Toolbox can also be used to showcase the profile functionality, as shown in the figure **IoT Toolbox Beacon Demo** below.

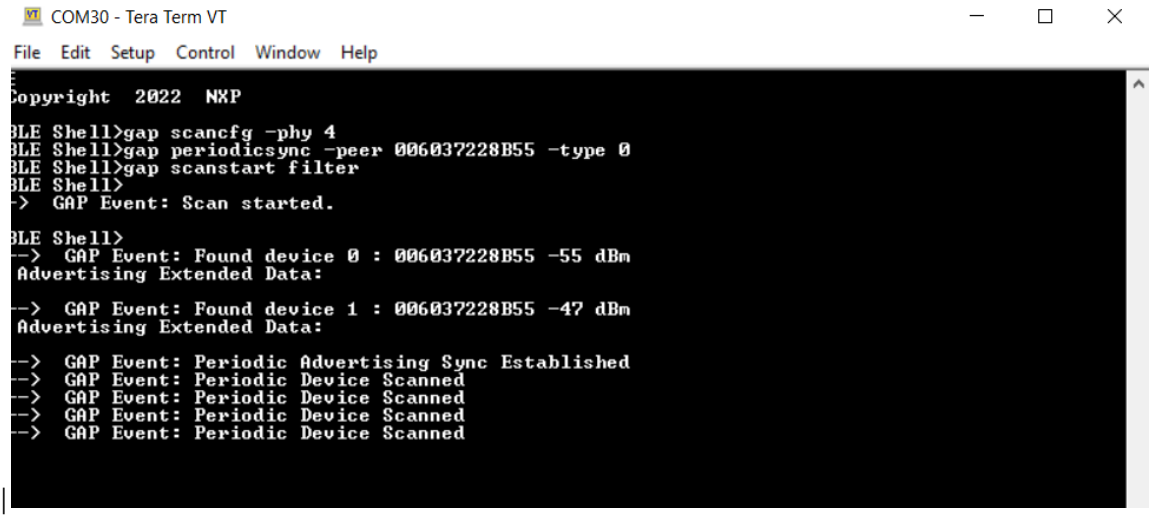
7% 10:25
IoT Toolbox
Beacons
STOP
Manufacturer ID: NXP
UUID: 1B5ED501-83FD-A341-A845-80833D843013
A: 0
B: 0
C: 0
RSSI: -55 dBm

Parent topic: Beacon



Beacon usage with extended advertising

To use the Beacon application with the advertising extensions capabilities, the gBeaconAE_c define option must be set to 1. Doing this enables the usage of extended advertising and periodic advertising. The application cycles between these modes are in the following manner:

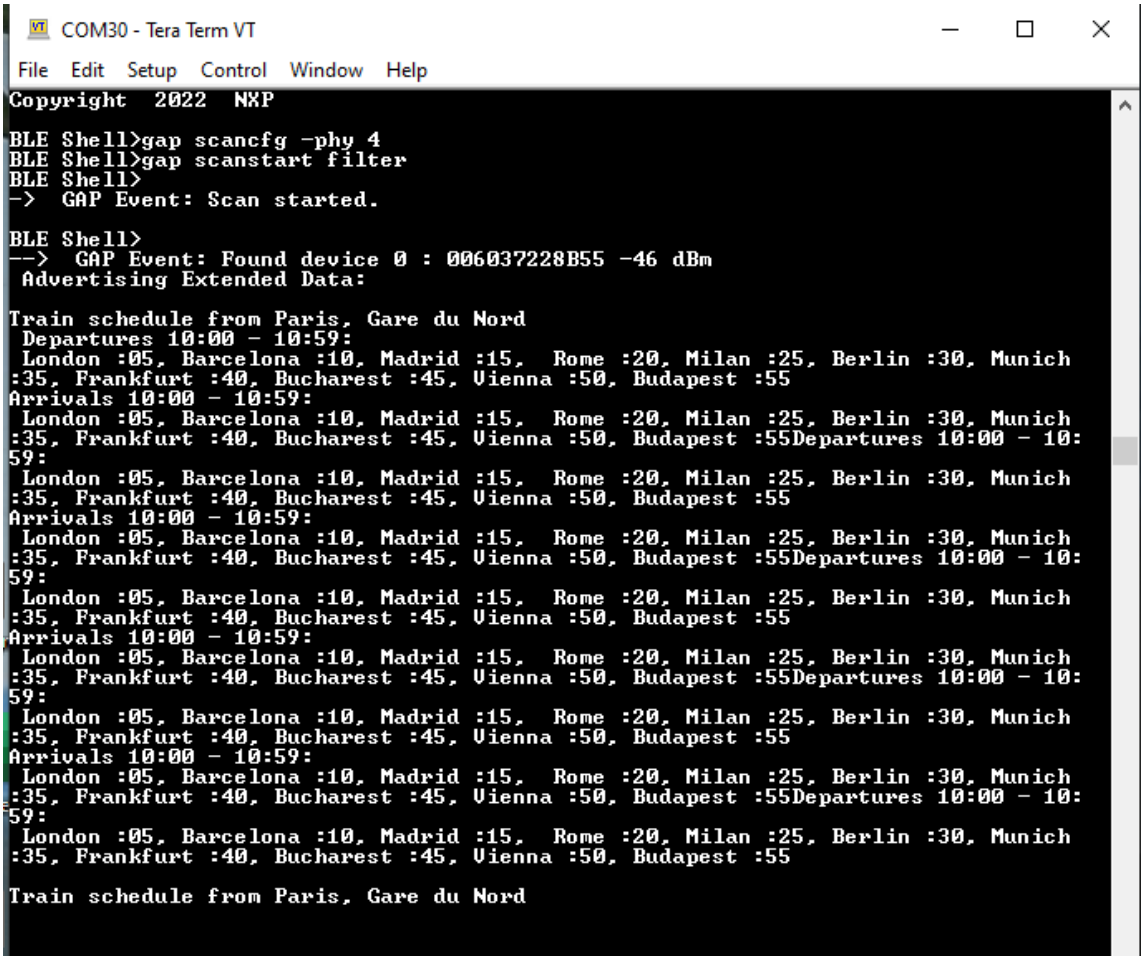


- The first **ADVSW** press starts legacy advertising, **CONNLED** turns solid.
- The second **ADVSW** press stops legacy advertising and starts extended advertising, **CONNLED** turns off, **EXTADVLED** turns solid.
- The third **ADVSW** press stops extended advertising carrying data and then starts extended advertising without data and periodic advertising, **EXTADVLED** starts flashing.
- The fourth **ADVSW** press stops periodic advertising and extended advertising without data and starts legacy advertising and extended advertising, both **CONNLED** and **EXTADVLED** turn solid.
- The fifth ADVSW press stops them all, both **CONNLED** and **EXTADVLED** turn off.

Not all smartphones support extended advertising, hence a different method to view the AE beacon is to use the ble_shell application. In order to do this, perform the following steps:

1. Flash a board with the beacon application, as described above.
2. Flash a board with the ble_shell application, as described in Bluetooth LE Shell and connect to it using a serial port.
3. Press the **ADVSW** button two times on the beacon to start extended advertising on the coded PHY.
4. To view the advertising data, enter the following commands in the shell terminal to set the scanning PHY to coded and start scanning. See the figure below.

5. To start the periodic advertising, press **ADVSW** button again on the beacon.
6. To sync with the beacon, issue the following commands on the shell terminal as shown in the figure below.



The peer parameter of the periodicsync command is the public address of the beacon.

Extended Advertising with very large data

To use very large advertising data for extended advertising, set the gBeaconLargeExtAdvData_c define to 1. The same steps are used to view the data using ble_shell :

1. Flash a board with the beacon application.
2. Flash a board with the ble_shell application, as described in Bluetooth LE Shell and connect to it using a serial port.
3. Press the **ADVSW** button two times on the beacon to start extended advertising on the coded PHY.
4. To view the advertising data, enter the following commands in the shell terminal to set the scanning PHY to coded and start scanning. See the figure below.

Parent topic:*Bluetooth LE stack and demo applications*

Bluetooth LE FSCI Black Box

This section describes the functionality, user interactions, and testing methods for the Bluetooth LE FSCI Black Box demo application.

Description

The Bluetooth LE FSCI Black Box demo application gives access to the Bluetooth LE Host Stack via a serial interface using the FSCI protocol. See the *FSCI (Framework Serial Communication Interface) manual* for the format of the FSCI commands and a full list of supported commands.

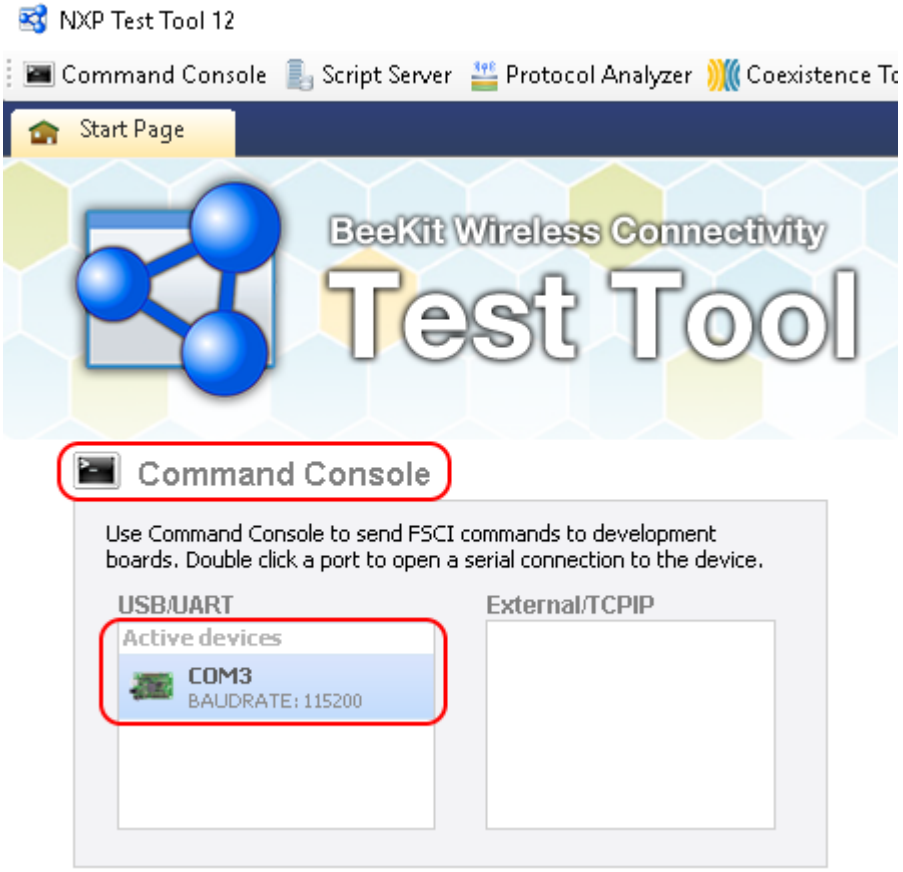
The demo can be used with the Test Tool for Connectivity Products. Command Console application can be downloaded from the NXP website or using a custom application that supports the FSCI protocol and commands.

Parent topic: Bluetooth LE FSCI Black Box

Supported platforms

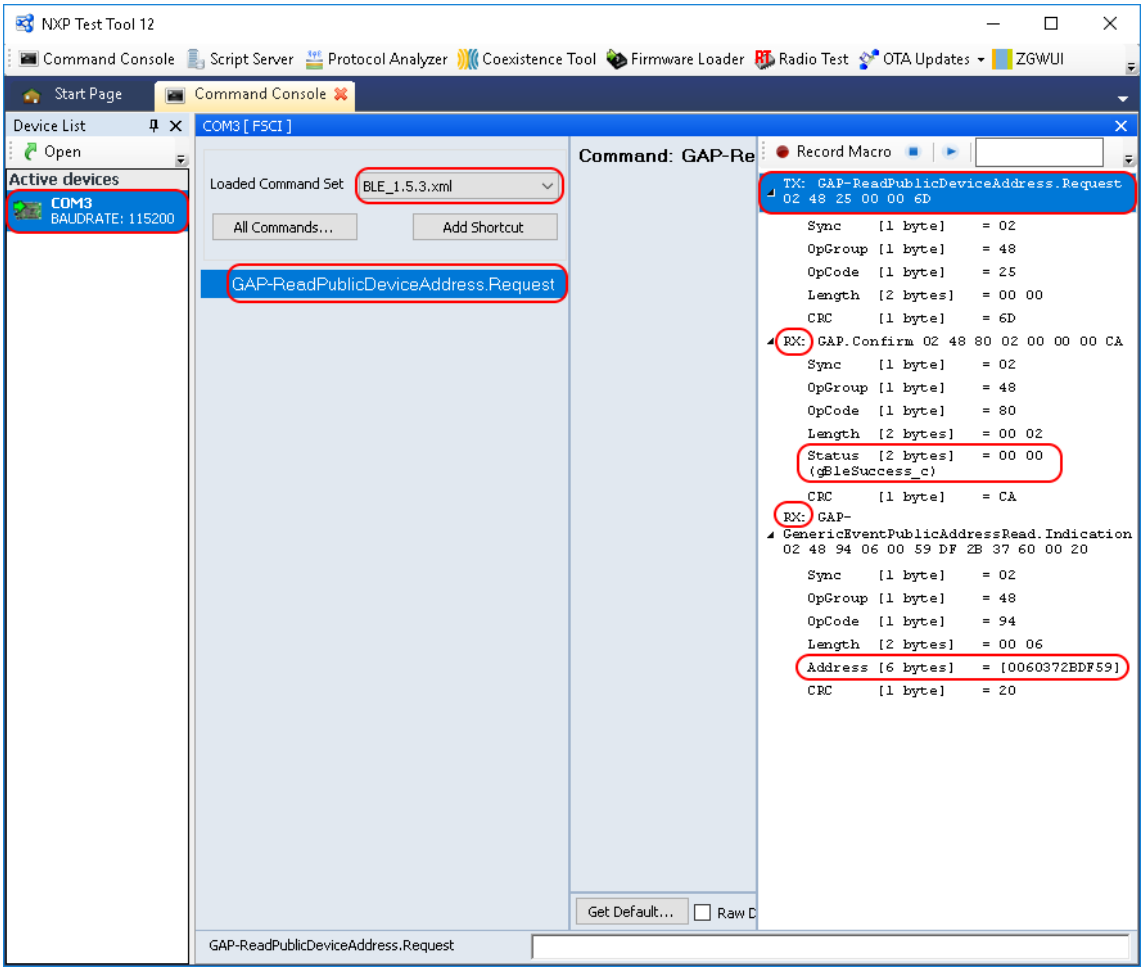
The following platforms support Bluetooth LE FSCI Black Box application:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK



- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK
- FRDM-KW43

Parent topic: Bluetooth LE FSCI Black Box



Usage with Test Tool for connectivity products

The Bluetooth LE FSCI Black Box demo application is designed to be used via serial interface. This can be done using the TEST Tool for Connectivity Products – Command Console application as described below.

1. Download the demo application onto a supported board.
2. Connect the board to a USB port of the PC. The UASB COM port drivers must be installed properly and a COM port corresponding to the board should be available.
3. Open the Test Tool application and connect to the serial port corresponding to the board on which the Bluetooth LE FSCI Black Box application runs. See Figure. The serial communication parameters are: baud rate 115200, 8N1, and no flow control.

4. Select the appropriate Test Tool XML file from the drop-down list for the release being used and send commands to the application. An example is shown in Figure.

Parent topic: Bluetooth LE FSCI Black Box

Parent topic:*Bluetooth LE stack and demo applications*

EATT Central

This section describes the implemented profiles and services, user interactions, and testing methods for the EATT Central application.

Implemented profiles and services

The EATT Central application implements a GATT server and the following profiles and services:

- Generic Attribute Profile

The application behaves as a GAP central node. It searches for an EATT peripheral to connect to. After connecting, it performs service discovery, initiates an EATT connection and configures indications on the peripheral for services A and B. The Central reports the received service data and the steps taken during the setup on a terminal connected to an UART port.

Parent topic:EATT Central

Supported platforms

The EATT Central application is supported on the following platforms:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK

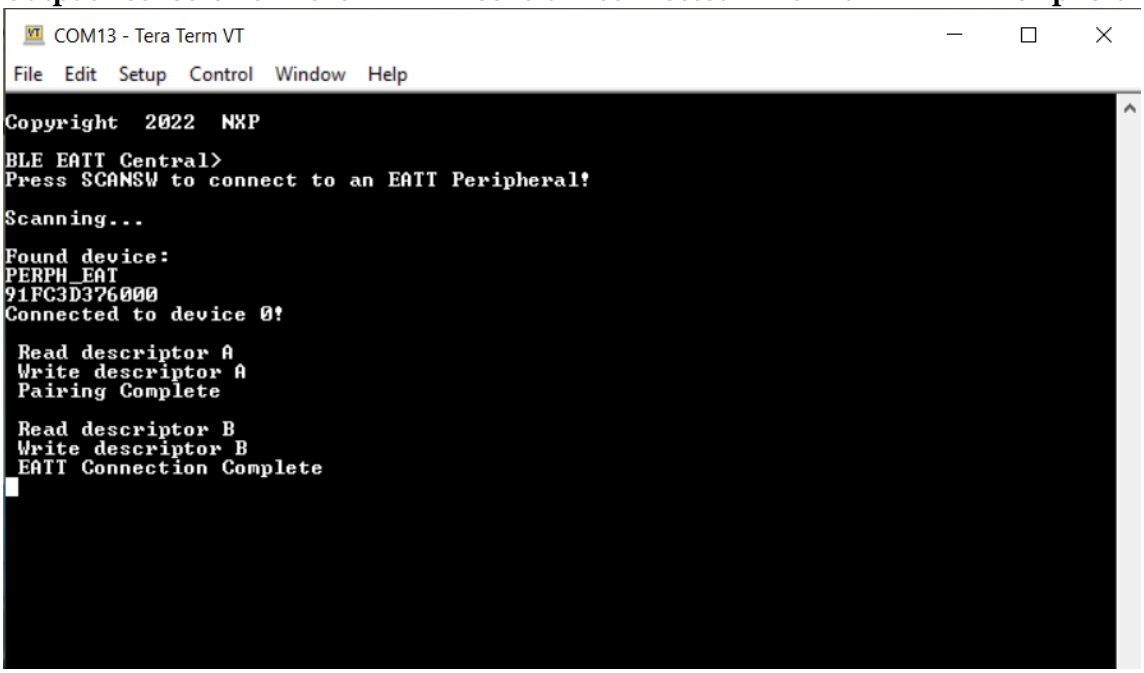
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK
- FRDM-KW43

Parent topic:EATT Central

User interface

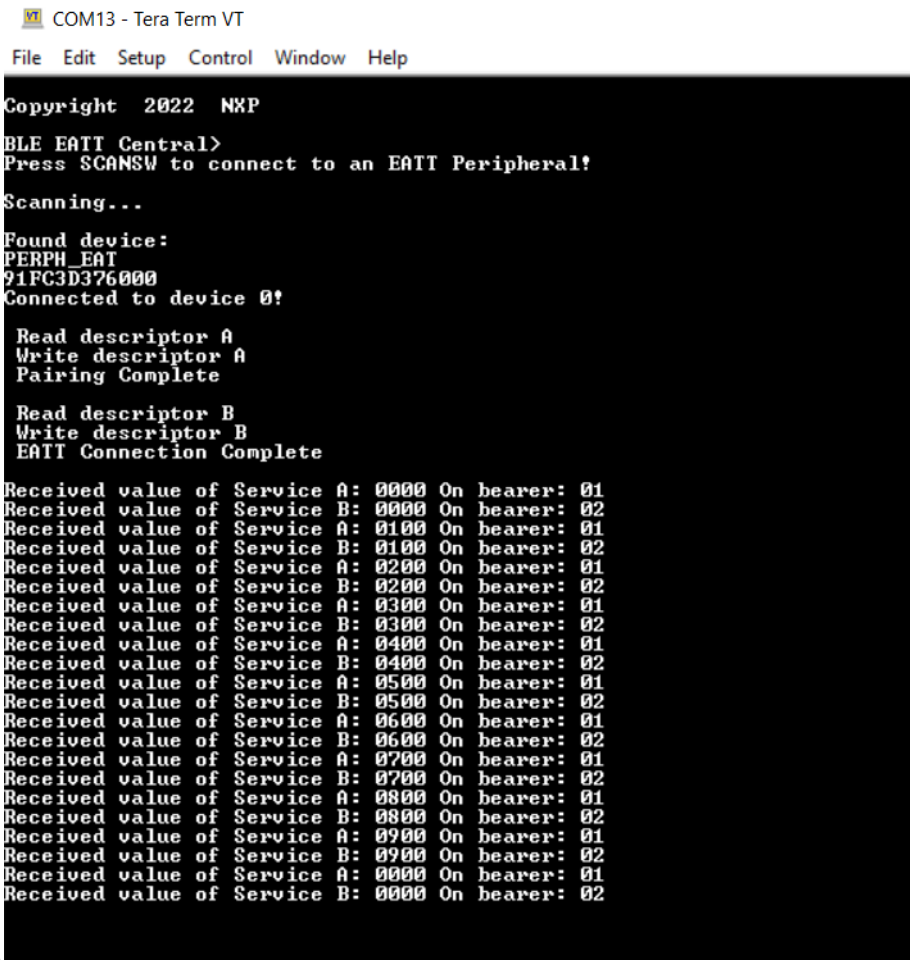
After flashing the board, the central is in Idle mode (all LEDs flashing). To start scanning, press the **SCANSW** button. After connecting to the peripheral, the **CONNLED** turns solid. The data information together with the bearer it was received on is sent over UART. To disconnect the node, hold the **SCANSW** button pressed for 2-3 seconds. The node then restarts scanning.

Parent topic:EATT Central



Switches and pins

Usage



The application can be tested using another board flashed with the EATT Central application as described in the EATT Peripheral.

1. Open a serial port terminal and connect it to board, in the same manner described in Testing devices. The start screen is displayed after the board is reset.
2. To start scanning for devices, press the **SCANSW** button on the EATT Central board. To make it enter discoverable mode, perform the same step on the EATT Peripheral board. The host connects with the board after it sees it advertise the service A and service B UUIDs. After connecting, the central performs service discovery, indicates its EATT support to the server by writing the Client Supported Features characteristic, enables indications for services A and B, and then initiates an EATT connection with the server. See the figure below.

   Output console on the EATT Central connected with an EATT Peripheral

3. After the EATT connection is complete, the console displays the received data and the bearer on which it was sent, as shown in the figure below.

Output console on EATT Central

Parent topic:EATT Central

Parent topic:*Bluetooth LE stack and demo applications*

EATT Peripheral

This section describes the implemented profiles and services, user interactions, and testing methods for the EATT Peripheral application.

Implemented profiles and services

The EATT Peripheral application implements a GATT server and the following profiles and services:

- Battery Service v1.0
- Device Information Service v1.1
- Generic Attribute Profile

The Generic Attribute Profile includes the Server Supported Features characteristics, which is used to indicate EATT support to the peer, and the Client Supported Features characteristic, which is used by the peer to indicate its own EATT support.

The application behaves as a GAP peripheral node. It enters GAP General Discoverable Mode and waits for a GAP central node to connect. The application implements two custom services, Service A and Service B. After the EATT connection is completed, the peer must enable indications for the two services to periodically receive profile data over EATT.

Parent topic:EATT Peripheral

Supported platforms

The EATT Peripheral application is supported on the following platforms:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK
- FRDM-KW43

Parent topic:EATT Peripheral

User interface

After flashing the board, the peripheral is in idle mode (all LEDs flashing). To start advertising, press the ADVSW button. When in GAP Discoverable Mode, **CONNLED** is flashing. When a central node connects to the peripheral, **CONNLED** turns solid. The node then waits for an EATT connection request and for the client to configure indications for the two services. The service information is sent over enhanced bearers only. The values indicated are cycled between 0 and 10. To disconnect the node, hold the ADVSW button for 2-3 seconds. The node then re-enters GAP Discoverable Mode and starts advertising.

Parent topic:EATT Peripheral

Switches and pins

Usage

The application can be tested using another board flashed with the EATT Central application as described in the EATT Central Section.

Parent topic:EATT Peripheral

Parent topic:*Bluetooth LE stack and demo applications*

FSCI Bridge

This section describes the functionality, user interactions, and testing methods for the FSCI Bridge demo application.

Description

The FSCI Bridge demo application is a demonstration of the Extended NBU architectural concept, where the Bluetooth LE Host Stack and the Link Layer both run on the NBU core, while the user-facing application runs on the Application core. The communication between the application and the Host is done via the FSCI protocol running on the inter-core RPMSG transport

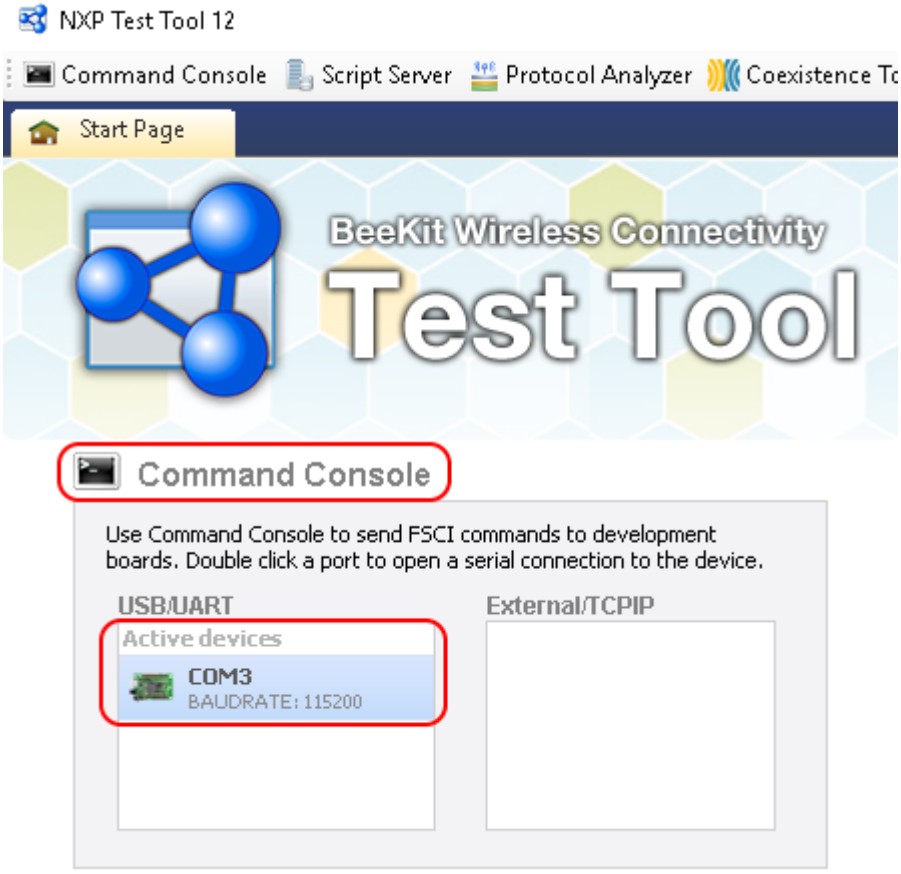
The FSCI Bridge runs on the Application core and it is a simple application whose purpose is to pass FSCI commands received over the serial interface to the NCP FSCI Black Box running on the NBU core. Effectively, the functionality is identical to the regular Bluetooth FSCI Black Box application.

The demo can be used with the Test Tool for Connectivity Products - Command Console application which can be downloaded from the NXP website or using a custom application that supports the FSCI protocol and commands.

Parent topic:FSCI Bridge

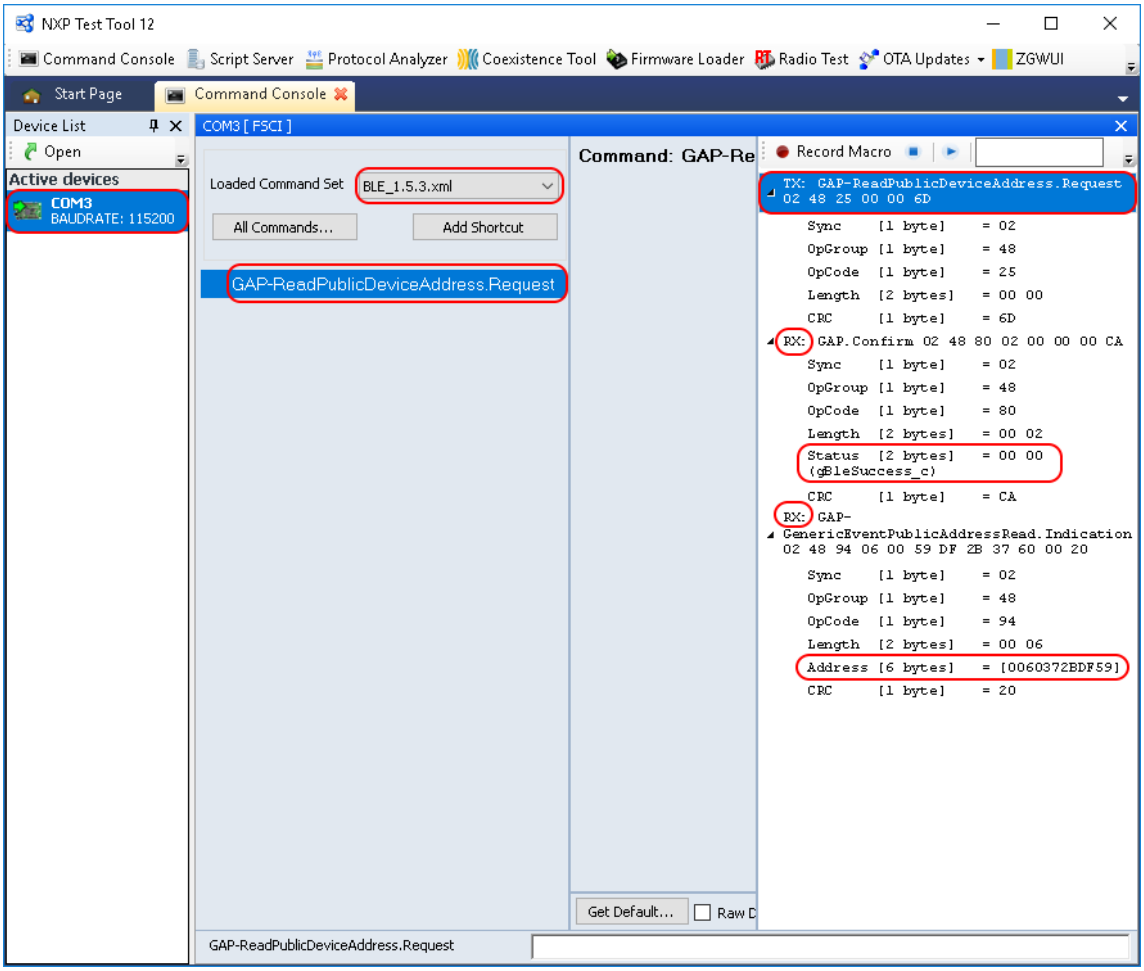
Supported platforms

The following platforms support the FSCI Bridge application:



- MCX-W72-EVK
- FRDM-MCXW72

Parent topic:FSCI Bridge



Usage with Test Tool for connectivity products

The FSCI Bridge demo application is designed to be used via serial interface. This can be done using the TEST Tool for Connectivity Products – Command Console application as described below.

1. Download the FSCI Bridge application onto a supported board's Application core, together with the NCP FSCI Black Box application on the NBU core.
2. Connect the board to a USB port of the PC. The USB COM port drivers must be installed properly and a COM port corresponding to the board should be available.
3. Open the Test Tool application and connect to the serial port corresponding to the board on which the FSCI Bridge application runs. See Figure. The serial communication parameters are: baud rate 115200, 8N1, and no flow control.

4. Select the appropriate Test Tool XML file from the drop-down list for the release being used and send commands to the application. An example is shown in Figure.

Parent topic:FSCI Bridge

Parent topic:*Bluetooth LE stack and demo applications*

HCI Black Box

This section describes the functionality, user interactions, and testing methods for the Bluetooth LE HCI Black Box demo application.

Description

The Bluetooth LE HCI Black Box demo application gives access to the Bluetooth LE Controller via a serial interface using the HCI protocol over serial interface. Refer to the Bluetooth Specification for the format of HCI commands and events over serial interface and the full list of supported commands and events.

The demo can be used with the Test Tool for Connectivity Products. The Command Console application can be downloaded from the NXP website. Alternatively you can also download it using a custom application that supports the HCI protocol and commands and events over serial interface.

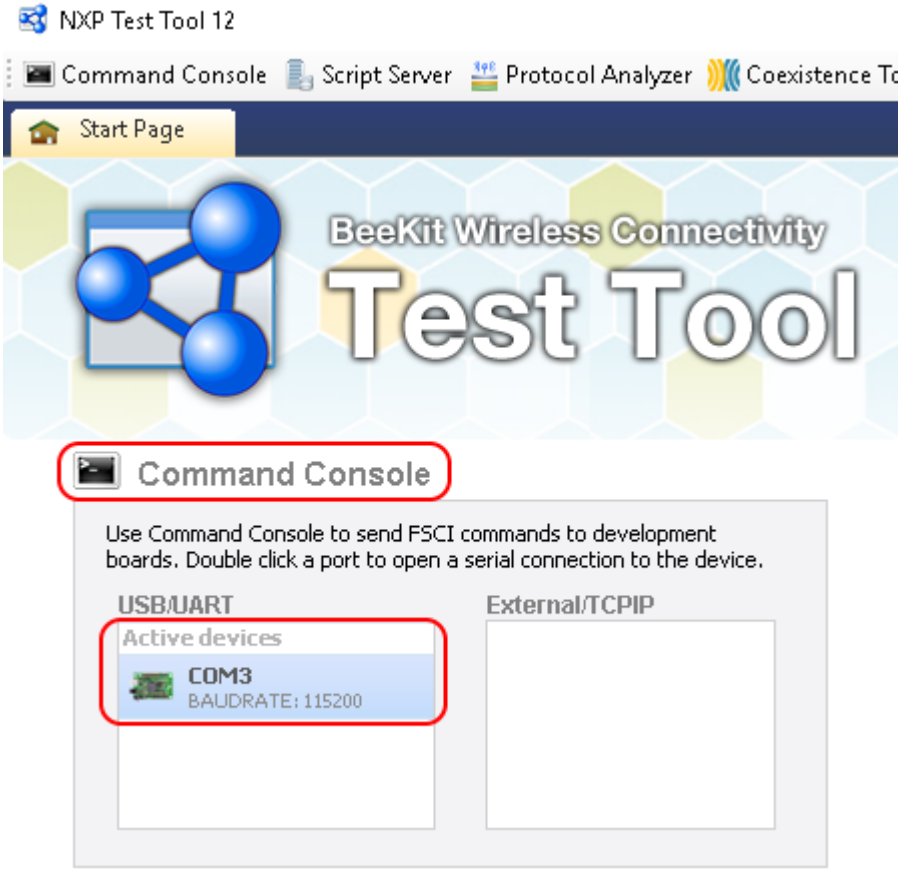
Note: The HCI protocol encapsulation is dependent on the type of interface it is being used on. See the Bluetooth Specification for the HCI message format on each type of supported interface.

For instructions using the Bluetooth LE HCI Black Box with a serial terminal application or the hcitool in Linux, check the article "FRDM-KW40Z Bluetooth LE Controller Usage with the Linux hcitool".

Parent topic:HCI Black Box

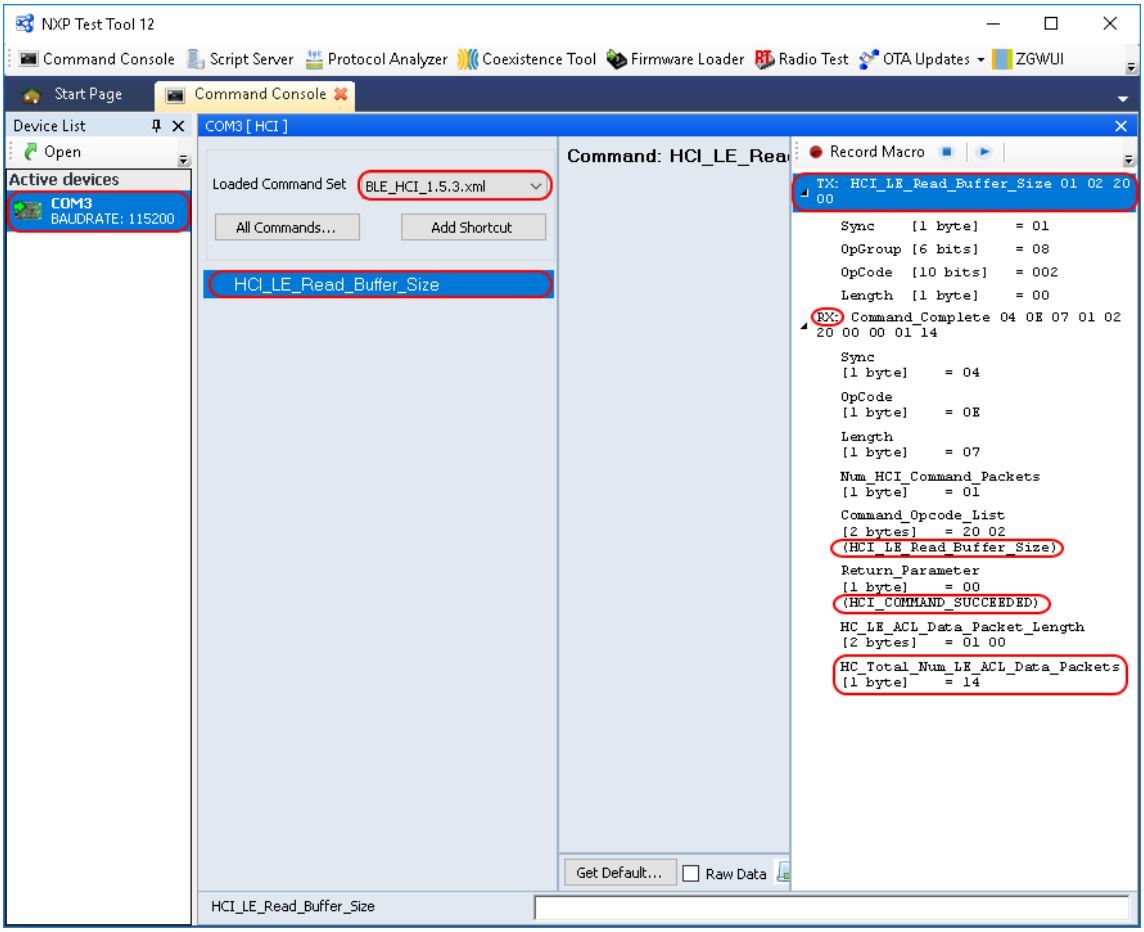
Supported platforms

The following platforms support the HCI Black Box application:



- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK
- FRDM-KW43

Parent topic:HCI Black Box



Usage with Test Tool for Connectivity products

The Bluetooth LE HCI Black Box demo application is designed to be used via serial interface. This can be achieved using the TEST Tool for Connectivity Products – Command Console application as described below.

1. Download the demo application to a supported board.
2. Connect the board to a USB port of the PC. The UASB COM port drivers must be installed properly and a COM port corresponding to the board should be available.
3. Open the Test Tool application and connect to the serial port corresponding to the board on which the Bluetooth LE HCI Black Box application runs. The serial communication parameters are: baud rate 115200, 8N1, and no flow control. See the figure **Test tool command console serial port selection** below.

4. Select the appropriate Test Tool HCI XML file from the drop-down list for the release you are using. Send a few commands to the application. An example is shown in the figure **HCI black box command example** below.

HID Device (Mouse)

This section describes implemented profiles and services, user interactions, and testing methods for the HID mouse application.

Implemented profiles and services

The HID Device application implements a GATT server and the following profile and services.

- HID over GATT Profile v1.0
- Human Interface Device Service v1.0
- Battery Service v1.0
- Device Information Service v1.1

The application behaves as a GAP peripheral node. It enters GAP General Discoverable Mode and waits for a GAP central node to connect. Security on the services and bonding is enabled on this device.

When the GATT client configures notification, the application starts sending HID reports every two seconds with the movement of the MOUSE_STEP. The demo moves the cursor in a square pattern between AXIS_MIN and AXIS_MAX. The report contains 3 bytes, one for button status, one for X axis, and one for Y axis. The report descriptor matches the example in chapter E.10 from

the USB Device Class Definition for Human Interface Devices (USB HID Specification), Version 1.11.

Parent topic:HID Device (Mouse)

Supported platforms

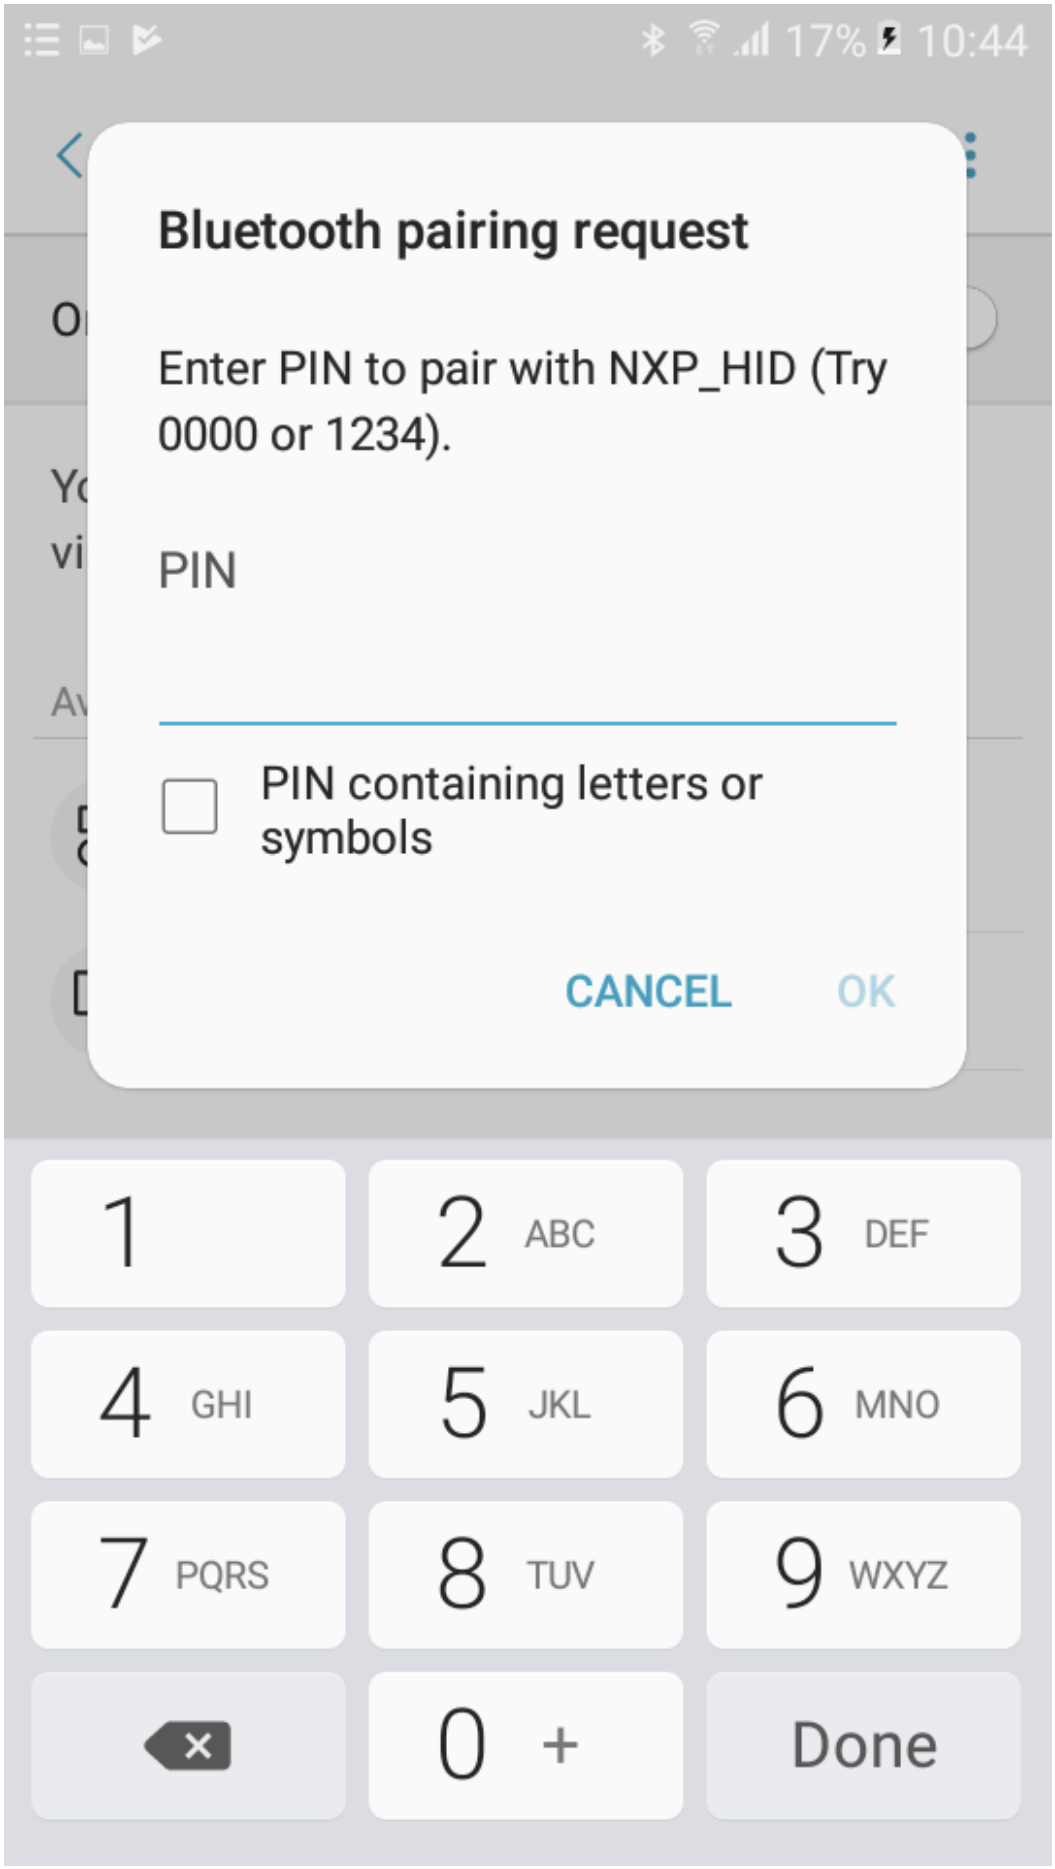
The following platforms support the HID Device application:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK
- FRDM-KW43

Parent topic:HID Device (Mouse)

User interface

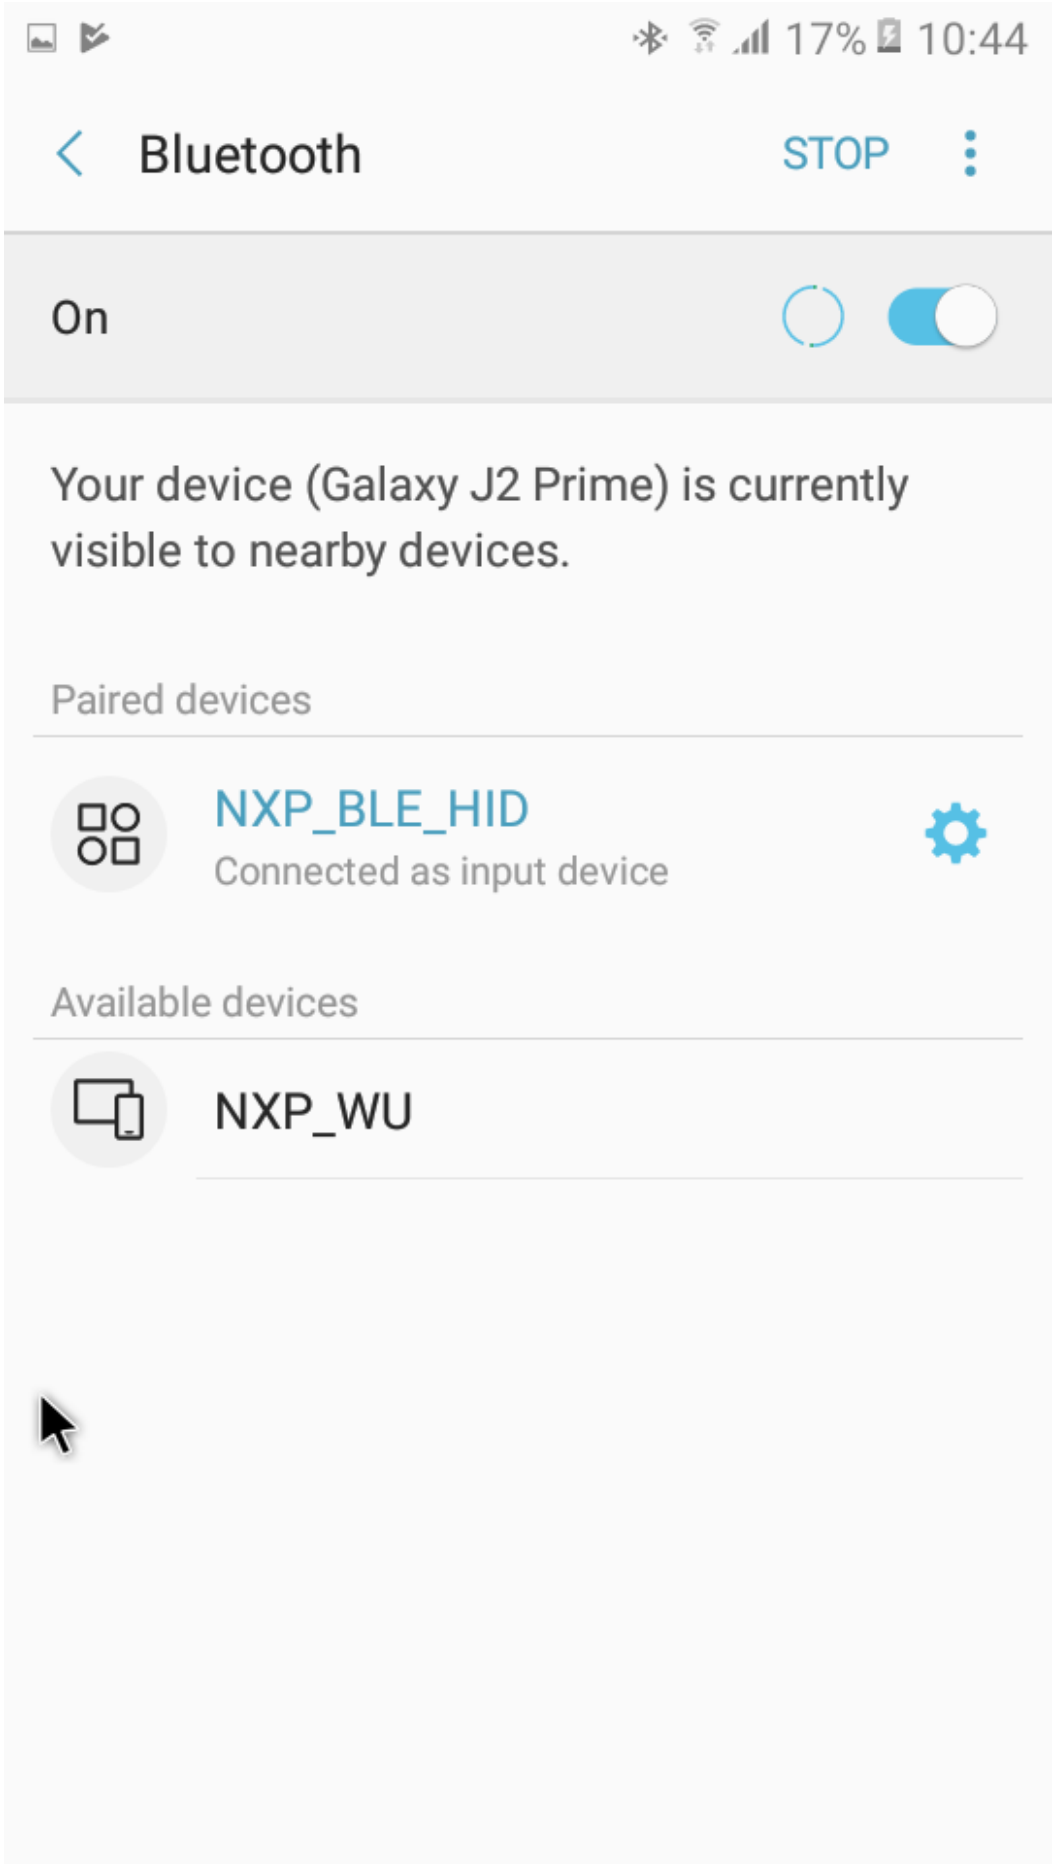
After flashing the board, the device enters Idle mode with all LEDs flashing. To start advertising, press the **ADVSW** button. In GAP Discoverable mode, **CONNLED** is flashing. When the central node connects to the peripheral, **CONNLED** turns solid. To disconnect the node, hold the **ADVSW** pressed for 2-3 seconds. The node then re-enters GAP Discoverable Mode.



Parent topic:HID Device (Mouse)

Switches and pins

Usage



The HID mouse can be connected to any Bluetooth Smart Ready products available on the market that supports HID devices or to another supported platform running the HID Host example (setup steps detailed in the HID Host section).

To make the HID mouse visible, press the **ADVSW** button to start sending advertisements, which causes CONNLED to start flashing. See the figure **Enter PIN prompt on Android platform** below.

HID Host

This section presents the implemented profiles and services, user interactions, and testing methods for the HID Host application.

Implemented profiles and services

The HID Host application implements a GATT client or server for the following profile and service.

- HID over GATT Profile v1.0
- Battery Service v1.0
- Device Information Service v1.1

The application behaves as a GAP central node. It enters the GAP Limited Discovery Procedure and searches for HID devices to connect to. After connecting with the peripheral, it configures notifications and displays the received HID reports on a terminal connected to the UART port. The application uses pairing with bonding by default. When connected with the HID Device application, it sends the 999999 passcode to the host stack by default.

Parent topic:HID Host

Supported platforms

The following platforms support the HID Host application:

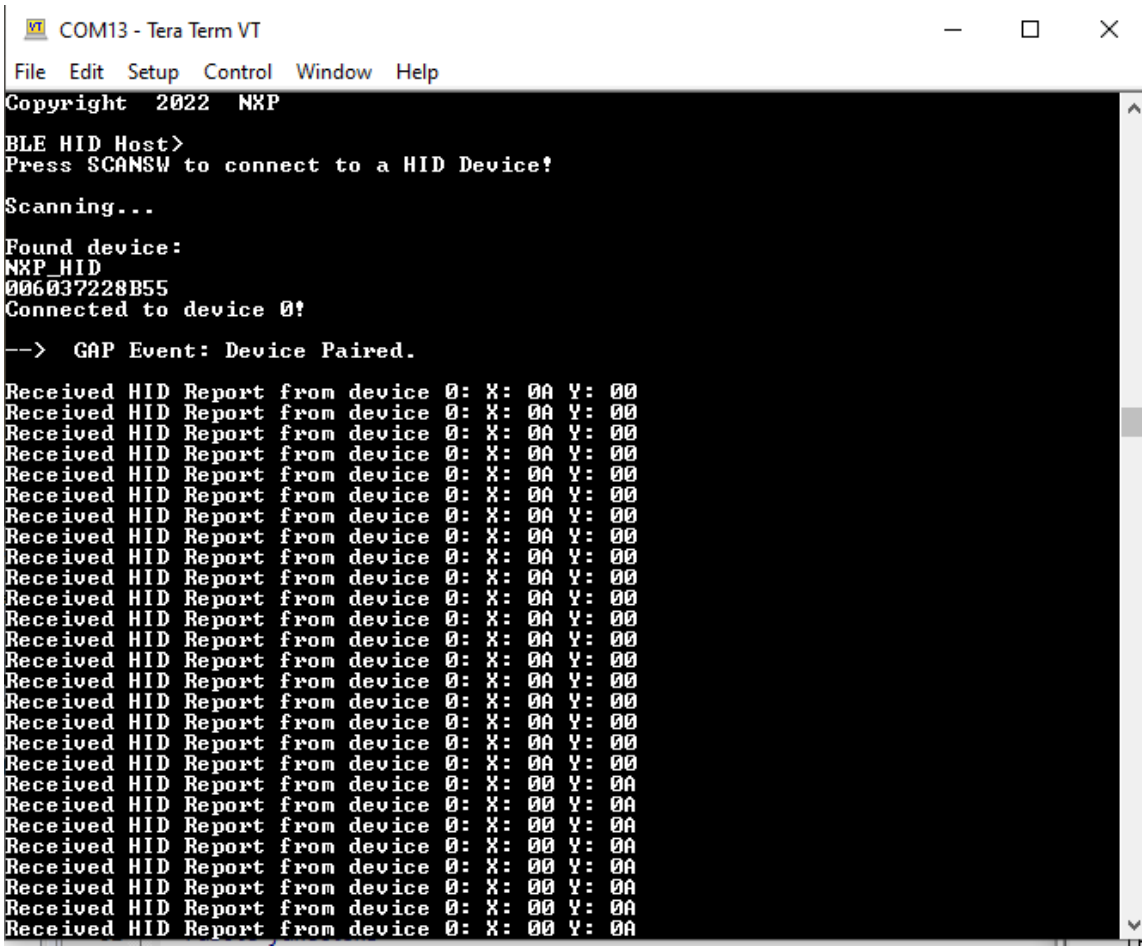
- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK
- FRDM-KW43

Parent topic:HID Host

User interface

After flashing the board, the device is in idle mode (all LEDs flashing). To start scanning, press the **SCANSW** button. When in GAP Limited Discovery Procedure, **CONNLED** is flashing. When the central node connects to the peripheral, **CONNLED** turns solid. To disconnect the node, hold the **SCANSW** button pressed for 2-3 seconds. The node then re-enters GAP Limited Discovery Procedure.

Parent topic:HID Host

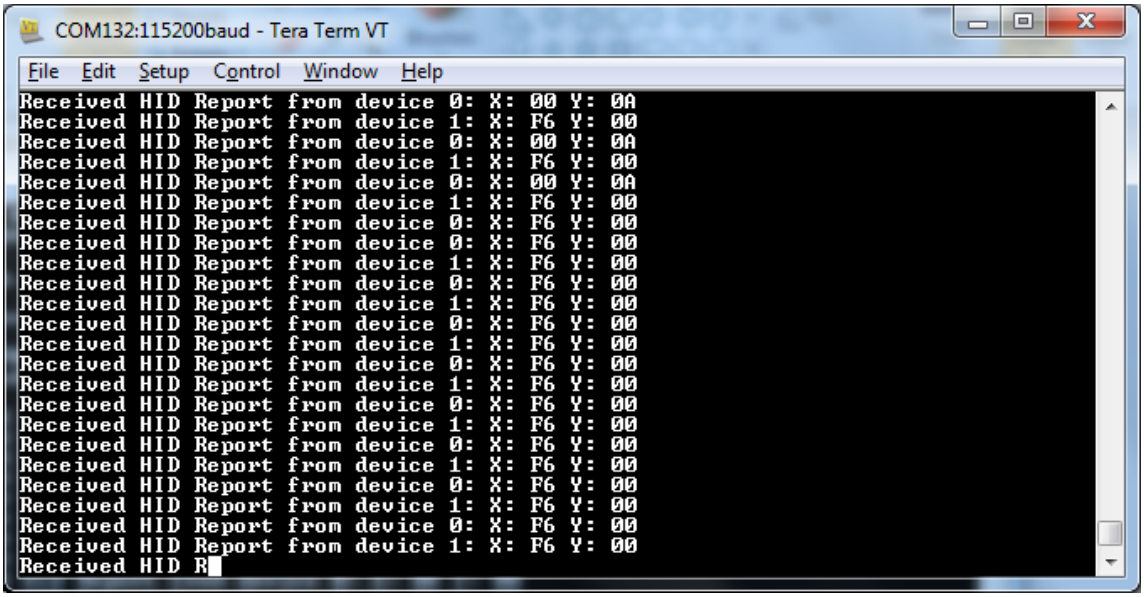


Switches and pins

Usage

The application is built to work only with the HID Device application presented in HID Device (Mouse). It supports up to 2 peripherals connected at the same time.

1. Open a serial port terminal and connect it to board, in the same manner described in Testing devices. The start screen is displayed after the board is reset.



2. To start scanning for devices, press the **SCANSW** button on the HID Host board. To make it enter discoverable mode, perform the same step on the HID device board. The host connects with the board after it sees it advertise the HID service, connects to it, and configures report notifications. The device then starts sending HID reports, as shown in Figure.

HID host

3. To connect a second HID device, press again the **SCANSW** button on the HID Host board to start scanning for devices. Do the same on the second HID device board to make it enter discoverable mode. The host connects with the board after it sees it advertise the HID service, connects to it, and configures report notifications. The device then starts sending HID reports. The console displays reports from both devices, as shown in Figure.

Localization Reader

This section describes the functionality of the Localization Reader demo application.

Please check out the *Localization Reader* section in the Bluetooth Low Energy Localization Application Note.

Parent topic:*Bluetooth LE stack and demo applications*

Localization Reader Host

This section describes the implemented profiles and services, user interactions, and testing methods for the Localization Reader Host application.

Description

The Loc Reader Host application is a Bluetooth Low Energy (BLE) localization application that runs on the application core of dual-core NXP platforms. It works in conjunction with the ncp_loc_reader application running on the radio core to perform distance measurement and localization using Channel Sounding (CS) technology.

Dual-Core Architecture

The application is part of a dual-core system where:

- **Core 0 (Application Core)**: Runs loc_reader_host
  - Receives uncompress IQ measurement data from Core 1 via FSCI messages
  - Executes localization algorithms (RADE, CDE)
  - Displays results via UART shell
- **Core 1 (Radio Core)**: Runs ncp_loc_reader
  - Handles BLE stack and Channel Sounding procedures
  - Collects and transmits uncompress local/remote IQ data to Core 0

Inter-Core Communication

Cores communicate using FSCI messages with event types:

- **gIQLocalTrStart_c/Cont_c/End_c**: Local uncompress IQ data fragments
- **gIQRemoteTrStart_c/Cont_c/End_c**: Remote uncompress IQ data fragments

Each message includes device ID, event type, and payload data (up to gFsciMaxPayloadLen_c).

Data Flow

1. Core 1 performs CS procedure and collects uncompress IQ samples
2. Core 1 fragments and transmits data to Core 0 via FSCI
3. Core 0 reassembles fragments into csAppData_t buffers
4. Core 0 runs localization algorithms and displays results

Parent topic: Localization Reader Host

Supported platforms

The following platforms support the Localization Reader Host application:

- MCX-W72-EVK
- FRDM-MCXW72

Parent topic: Localization Reader Host

User interface

Ensure that both NCP Localization Reader (for the NBU core) and Localization Reader Host (for the Application core) have been flashed to the board.

The application can be controlled using a shell interface via the UART connection to the host computer.

The behavior of the application and the user interraction is exactly the same as *Localization Reader* application.

Parent topic: Wireless UART Host

Parent topic:*Bluetooth LE stack and demo applications*

Localization User Device

This section describes the functionality of the Localization User Device demo application.

Please check out the *Localization User Device* section in the Bluetooth Low Energy Localization Application Note.

Parent topic:*Bluetooth LE stack and demo applications*

Low-power temperature sensor and collector

This section describes the implemented profiles and services, user interactions, and testing methods for the temperature sensor application.

Implemented profiles and services

The Temperature Sensor application implements a GATT server, a custom profile and the following services.

- Temperature Service (UUID: 01ff0200-ba5e-f4ee-5ca1-eb1e5e4b1ce0)

- Battery Service v1.0
- Device Information Service v1.1

The application behaves as a GAP peripheral node. It enters GAP General Discoverable Mode and waits for a GAP central node to connect and configure notifications for the temperature value.

The Temperature service is a custom service that implements the Temperature characteristic (UUID: 0x2A6E) with a Characteristic Presentation Format descriptor (UUID: 0x2904), both defined by the Bluetooth SIG.

The Temperature Collector application implements a GATT client or server for the following profile and services.

- Temperature Service (UUID: 01ff0200-ba5e-f4ee-5ca1-eb1e5e4b1ce0)
- Battery Service v1.0
- Device Information Service v1.1

The application behaves as a GAP central node. It enters GAP Limited Discovery Procedure and searches for sensor devices to pair with. After pairing with the peripheral, it configures notifications and displays temperature values on a terminal connected to the UART port.

Both application uses pairing with bonding by default. When connected with the Low-Power Temperature Sensor application, the collector sends the 999999 passcode to the host stack by default.

Parent topic: Low-power temperature sensor and collector

Supported platforms

The Temperature Sensor and Collector applications are supported by the following platforms:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK
- FRDM-KW43

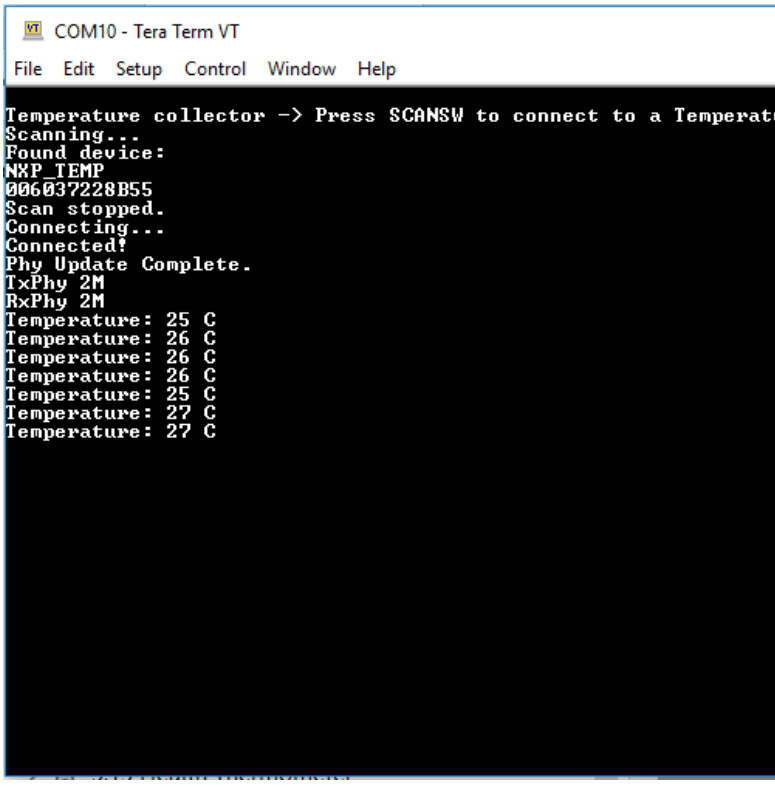
Parent topic: Low-power temperature sensor and collector

User interface

After flashing the board, both nodes enter Low-power mode. In case the sensor is put in deep sleep, press **WAKESW** or **RESET**. To flash the board in case the sensor is put in deep sleep, press either **WAKESW** or **RESET** button. By default, the application is configured to be in low power mode, which disables LED support.

The user can manually change this configuration and enable LED support, else all subsequent LED behavior references are ignored and all LEDs are off. The devices disconnect and enter Deep-sleep only if low power is enabled. When the node is awake and communicating, **CONNLED** is on. To wake up the node, press the **WAKESW** button.

Parent topic: Low-power temperature sensor and collector



Switches and pins(Collector) Switches and pins(Sensor)

Usage

The setup requires two supported platforms, one for the temperature sensor and one for the temperature collector.

1. Open a serial port terminal and connect it to the temperature collector board, in the same manner as described in Testing devices. The start screen is displayed after the board is reset. At first the LEDs are off on both devices.
2. To start advertising on the sensor, press the WAKESW button and CONNLED lights up. The sensor enters into the Deep-sleep mode, which means that the MCU wakes up on any packet from the Link layer, in this case the connect request. If no connection is established in an interval of 30 seconds, the sensor stops advertising and enters into the Deep-sleep mode again. CONNLED turns off.
3. To start scanning on the collector, press the WAKESW button and CONNLED lights up. The device wakes up, enters into the Deep-sleep mode, scans, and connects to a compatible sensor device. If no connection is established within 30 seconds, the collector stops scanning and enters Deep-sleep mode again. CONNLED turns off.
4. If the collector connects to a sensor node, it bonds (if no bond was previously made), does service discovery (only the first time it connects with the sensor), and configures notification and waits for notifications from the sensor for 5 seconds. If no data is sent, the node disconnects and re-enters Deep-sleep mode. The sensor exits low power and sends a notification with the value of the temperature read through an ADC from the thermistor, if present, or random generated if not.

   Once the connection is established, the PHY is automatically updated to 2M, if both the sensor and the collector support this feature as shown in the figure below. The PHY update is configurable from the application.

Output Console on Temperature Collector

5. Subsequent key pressing triggers other notifications for the collector. If no key is pressed in an interval of 5 seconds, the sensor node disconnects and re-enters Deep-sleep mode.

Parent topic: Low-power temperature sensor and collector

Parent topic:*Bluetooth LE stack and demo applications*

Tire Pressure Monitoring System Sensor and Monitor

This section describes the implemented profiles and services, user interactions, and testing methods for the TPMS Sensor and TPMS Monitor applications.

Implemented profiles and services

The TPMS Sensor application implements a GATT server, the TPMS profile and the following services.

- Tire Pressure Monitoring System Service (TPMS)
- Battery Service v1.0
- Device Information Service v1.1

The application behaves as a GAP peripheral node. It enters GAP Limited Discoverable Mode to perform either connectable or non-connectable advertising. When performing connectable advertising, it waits for a Primary Monitor to connect and configure it, as defined by the TPMS Profile. When performing non-connectable advertising, it broadcasts packets containing the tire pressure and temperature values.

The TPMS Service is defined by the Bluetooth SIG.

The TPMS Monitor application implements a GATT client or server for the following profile and services.

- Tire Pressure Monitoring System Service (TPMS)
- Battery Service v1.0
- Device Information Service v1.1

The application behaves as a GAP central node. It enters GAP Limited Discovery Procedure and searches for connectable or non-connectable advertising packets from TPMS Sensors. When a TPMS Sensor is found, the Monitor can connect to it, pair, bond, and read/write TPMS characteristics as defined by the TPMS Profile. The Monitor can also receive non-connectable broadcast packets containing tire pressure and temperature values from sensors.

Parent topic:TPMS Sensor and Monitor

Supported platforms

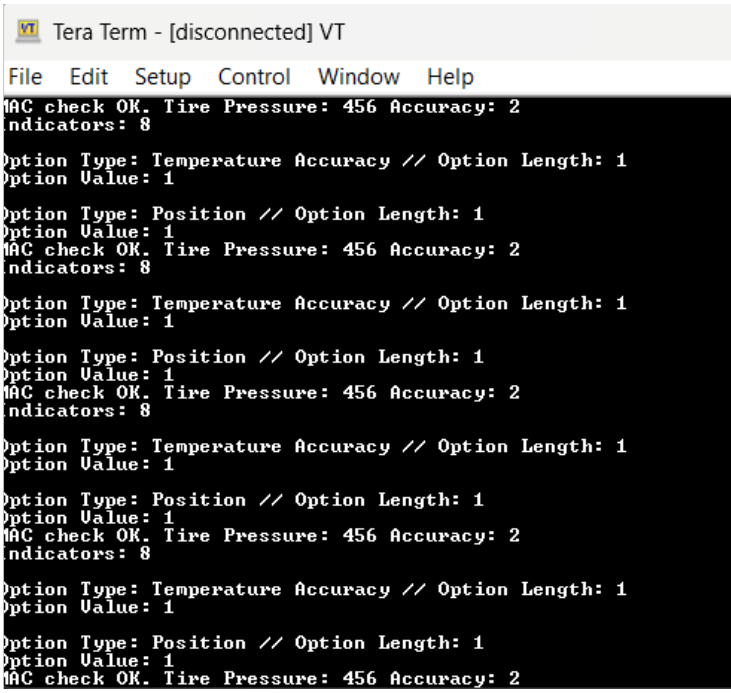
The TPMS Sensor and Monitor applications are supported by the following platforms:

- KW45B41Z-EVK
- KW47-EVK
- FRDM-KW43

Parent topic:TPMS Sensor and Monitor

User interface

After flashing, both devices are in idle mode. To start scanning on the TPMS Monitor, press the **SCANSW** button. To start advertising on the TPMS Sensor, press either the **CONNADVSW** or **NCONNADVSW** buttons. When in GAP Limited Discovery Mode or scanning mode, **CONNLED** is flashing on either device. When the devices connect, **CONNLED** turns solid. To disconnect the TPMS Monitor, hold the **SCANSW** button pressed for 2-3 seconds.



Parent topic:TPMS Sensor and Monitor

Switches and pins(Monitor) Switches and pins(Sensor)

Usage

The setup requires two supported platforms, one for the TPMS Sensor application and one for the TPMS Monitor application.

1. Open a serial port terminal and connect it to the TPMS Monitor board, in the same manner as described in Testing devices. The start screen is displayed after the board is reset.
2. To start connectable advertising on the TPMS Sensor, press the CONNADVSW button. The device will start advertising.
3. To start scanning on the TPMS Monitor, press the SCANSW button.
4. If the TPMS Monitor connects to a sensor node, it will:
    1. perform service discovery
    2. pair and bond to establish itself as a Primary Monitor
        1. if the Sensor already has a Primary Monitor, bonding will not be performed and the Monitor will have the role of Secondary Monitor
        2. The following steps assume the role is that of Primary Monitor
    3. read the TPMS Properties, TPMS Signing Key, TPMS Tire Pressure, TPMS Tire Temperature and TPMS Tire Acceleration characteristic values
    4. update the TPMS Duty Cycle by writing to the corresponding characteristic
    5. enable indications for the TPMS Signing Key characteristic
    6. enable notifications for the TPMS Tire Pressure and TPMS Tire Temperature characteristics
5. While in connection, pressing CONNADVSW on the TPMS Sensor will notify the Tire Pressure and Temperature to the Monitor, while pressing NCONNADVSW will update the Signing Key and indicate this to the Monitor.
6. At this point, the connection can be terminated by either disconnecting via long press of the SCANSW on the TPMS Monitor or by resetting the boards.
7. To start non-connectable advertising on the TPMS Sensor, press the NCONNADVSW button. The device will start advertising in non-connectable mode (if no Primary Monitor exists, the advertising will be connectable).
8. To start scanning on the TPMS Monitor, press the SCANSW button. The TPMS Monitor will display the TPMS data in the non-connectable advertising of the TPMS Sensor if it successfully authenticates the payload as described by the TPMS Profile specification.
9. To factory reset the Sensor, long press NCONNADVSW. For the Monitor, long press FACTORYRESETSW.

Output Console on TPMS Monitor

Parent topic:*Bluetooth LE stack and demo applications*

Low-power extended advertising Peripheral and Central

This section describes the implemented profiles and services, user interactions, and testing methods for the adv_ext_peripheral and adv_ext_central applications.

Implemented profile and services

The adv_ext_peripheral application implements a GATT server, a custom profile and the following services.

- Temperature Service (UUID: 01ff0200-ba5e-f4ee-5ca1-eb1e5e4b1ce0)
- Battery Service v1.0
- Device Information Service v1.1

The application behaves as a GAP peripheral node. It enters GAP General Discoverable Mode and waits for a GAP central node to connect and configure notifications for the temperature value.

The Temperature service is a custom service that implements the Temperature characteristic (UUID: 0x2A6E) with a Characteristic Presentation Format descriptor (UUID: 0x2904), both defined by the Bluetooth SIG.

The adv_ext_central application implements a GATT client or server for the following profile and services.

- Temperature Service (UUID: 01ff0200-ba5e-f4ee-5ca1-eb1e5e4b1ce0)
- Battery Service v1.0
- Device Information Service v1.1

The application behaves as a GAP central node. It enters GAP Limited Discovery Procedure and searches for peripherals devices to pair with. After pairing with the peripheral, it configures notifications and displays temperature values on a terminal connected to the UART port.

Both applications use pairing with bonding by default. When connected with the Low-Power Extended Advertising Peripheral application, the Extended Advertising Central application sends the 999999 passcode to the host stack by default.

To enable Periodic Advertising With Responses (PAWR), set the gAppPAWRSupport_d define 1 in app_preinclude.h.

In case PAWR is enabled and more than one ext_adv_centrals are to be synced with the PAWR train, a different response slot may be configured for each board using the gUserDefinedResponseSlot_c define in app_preinclude.h to avoid collisions. Otherwise, a random response slot will be chosen by the application after reset.

To enable Encrypted Advertising Data (EAD), set the gAppEADSupport_d define 1 in app_preinclude.h.

In case EAD is enabled, the advertising structures of gAdManufacturerSpecificData_c data type will be encrypted and transmitted over the air as gAdEncryptedAdvertisingData_c data type structures. On the receiver side, they will be decrypted and printed under the “Decrypted data :” text to mark them as EAD. This applies for extended advertising, periodic advertising, PAWR subevent data or responses.

Parent topic: Low-power extended advertising Peripheral and Central

Supported platforms

The following platforms support Extended Advertising Peripheral and Central applications:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK
- FRDM-KW43

Deep-sleep mode is used by default.

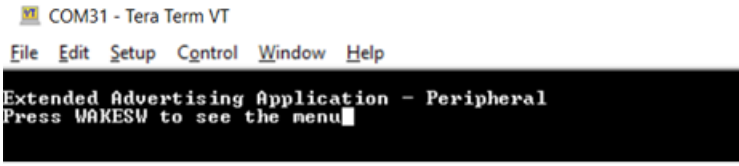
Parent topic: Low-power extended advertising Peripheral and Central

User interface

After flashing the board, both nodes enter Deep-sleep mode. To flash the board again, press **WAKESW**. The application default configuration enables low power that disables LED support. The user disables low power and enables LED support setting the gAppLowpowerEnabled_d define to 0. To wake up the node, press the **WAKESW** button. Both applications provide guidance over the UART.

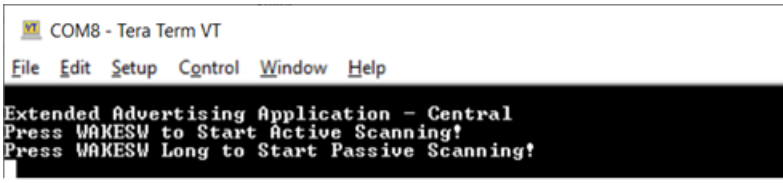
Open a serial port terminal using the following settings:

baud rate 115200, data bits 8, parity none, stop bits 1.



Parent topic: Low-power extended advertising Peripheral and Central

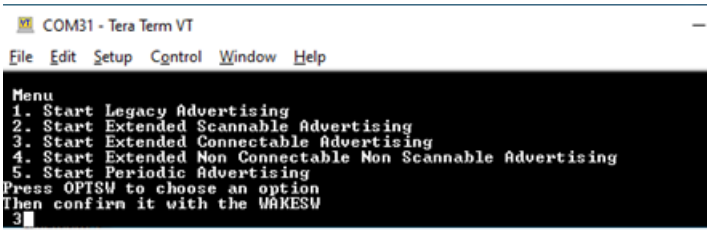
Switches and pins(Central) Switches and pins(Peripheral)



Usage

The setup requires two supported platforms, one for the adv_ext_peripheral, and one for the adv_ext_central.

1. Open a serial port terminal and connect it to each platform with the settings provided in the previous paragraph. The start screen is displayed after the boards are reset as shown in the figures below.



Advertizing external Peripheral start screen

Advertizing external Central start screen

2. On the board that implements the adv_ext_peripheral application, press the **WAKESW** button. The board exits Deep-sleep mode and displays the menu as shown in the figure below.

Choosing a menu option on adv_ext_peripheral

Use the **OPTSW** to choose an option. The option printed on the bottom changes every time the switch is pressed. When the option matches your intention (For example, 3 Starts Extended Connectable Advertising), press the **WAKESW** again to make a decision. The advertising type chosen is started and the board starts entering low-power between advertising events.

Next time, the **WAKESW** is pressed, an updated menu is printed (For example, at option 3 Stop Extended Connectable Advertising). There is no timeout for advertising. The board continues advertising until it is stopped, or a connection is established (for legacy and extended connectable advertising only) with an adv_ext_central device.

The connection is terminated five seconds after the central device configures notifications for the temperature value. When all advertising is off and all connections are terminated, the board enters low-power mode until the **WAKESW** button is pressed again.

When gAppLowpowerEnabled_d is set 0, LEDs are enabled. The ADVLED flashes whenever an advertising starts and is ON otherwise. The CONNLED flashes whenever there is a connection under way and is ON otherwise.

When PAWR is started , advertising data is transmitted on subevents zero and three and responses are expected on all 5 configured response slots of these subevents. The central application responds to the periodic data received with a six bytes data composed of a three bytes random number followed by a three bytes hash performed over the random number using the local IRK in the same fashion the RPA are generated. The advertiser prints the responses, uses the bonded devices IRKs to generate the hash over the random number and attempts to connect over PAWR with the responder in case the hashes match.

```

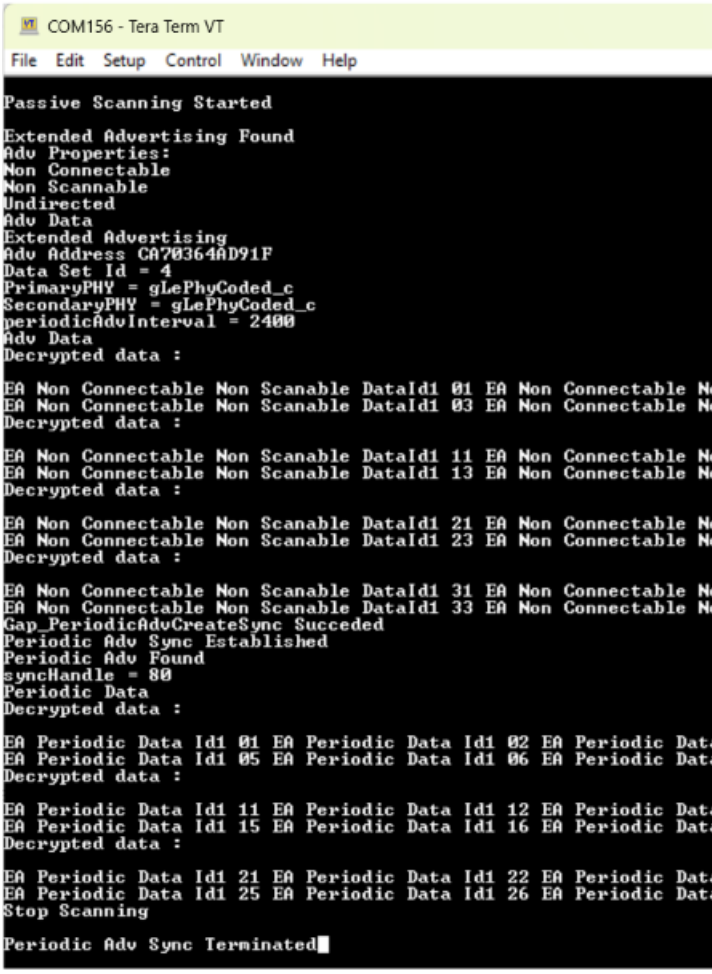
Adv Handle: 0
Subevent: 0
Response slot: 2
Response data: EFBE6E573231
```



(continues on next page)

(continued from previous page)

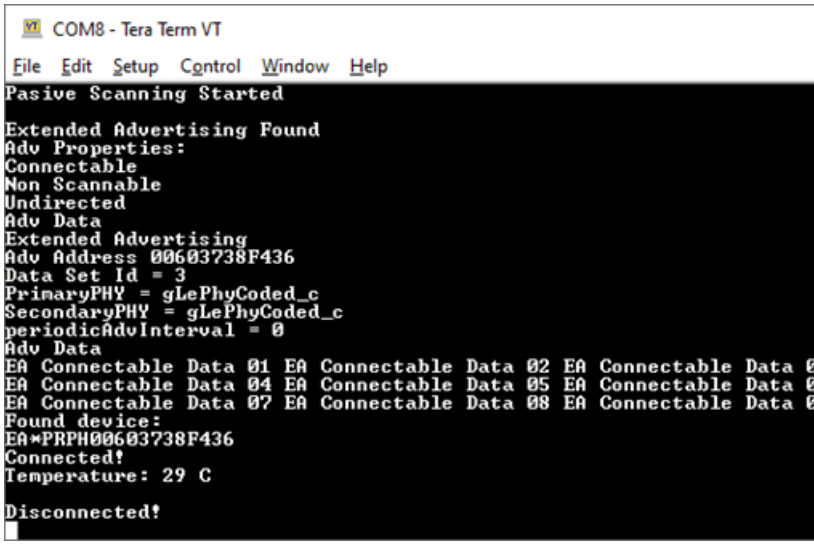
```
Periodic advertising response received
Adv Handle: 0
Subevent: 3
Response slot: 2
Response data: 021CED6395B8
PAWR Set Subevent Data Complete
```

3. On the board that implements the **adv_ext_central** application, there are two options: Press **WAKESW** to start active scanning or long press **WAKESW** to start passive scanning. If catching extended scannable advertising is not an option, choose passive scanning. Otherwise, select active scanning. The device wakes up, starts scanning, and enters Deep-sleep mode. The scanning ends when the 60 seconds timeout is reached or when a connection with an adv_ext_peripheral device is established.

   During scanning, all advertisements caught from adv_ext_peripheral devices are displayed on the terminal window as shown in Figure. When an extended non-connectable, non-scannable advertising with a periodic advertising attached is detected, the *adv_ext_central*device attempts to sync with the periodic advertising train and prints the periodic advertising data on the terminal window.

Advertising caught on adv_ext_central console

   If the PAWR support is enabled and the periodic advertising train the adv_ext_central has synced to is with responses the application attempts to sync with the subevents zero and three, periodic advertising data printed being slightly different. Also, the application responds to the periodic data received with a six bytes data composed of a three bytes random number followed by a three bytes hash performed over the random number using the local IRK in the same fashion the RPA are generated. The advertiser uses the bonded devices IRKs to generate the hash over the random number and attempts to connect over



PAWR with the responder in case the hashes match.

```
Passive Scanning Started

4. If the **adv_ext_central** connects to an **adv_ext_peripheral** device, it bonds (if no bond was previously made), does service discovery (only the first time it connects with the peripheral), configures notification and waits for notifications from the peripheral. If no data is sent within 5 seconds, the node disconnects and reenters Deep-sleep mode. The peripheral sends a notification with the value of the temperature read through an ADC from a thermistor, if present, or randomly generated, if not. When the central receives the notification, it displays it on the terminal window and disconnects in 5 seconds as shown in the figure below.

   When the 60 seconds timer expires or the connection ends, the device reenters Deep-sleep mode until the WAKESW is pressed again and all syncs with periodic advertising trains are terminated. If gAppLowpowerEnabled_d is set 0, LEDs are enabled. The SCANLED flashes, whenever the device is scanning and is ON otherwise. The CONNLED flashes, whenever there is a connection under way and is ON otherwise. See the figure below.

Connection on adv_ext_central console

When the PAWR support is enabled and a connection with a previously bonded device takes place over PAWR, the applications behavior is similar except in this case the adv_ext_central's role is peripheral and adv_ext_peripheral's role is central.

```

NCP FSCI Black Box

This section describes the functionality of the NCP FSCI Black Box demo application.

Description

The NCP FSCI Black Box application is a demonstration of the Extended NBU architectural concept, where the Bluetooth LE Host Stack and the Link Layer both run on the NBU core, while the

user-facing application runs on the Application core. The communication between the application and the Host is done via the FSCI protocol running on the inter-core RPMSG transport.

The NCP FSCI Black Box application runs on the NBU core and provides access to the Bluetooth LE Host Stack through FSCI to the application running on the Application core. It can be paired with the FSCI Bridge application to obtain a functionality that is identical to the regular Bluetooth FSCI Black Box application, or with the Wireless UART Host application to obtain a functionality that is identical to the regular Wireless UART application.

Parent topic:NCP FSCI Black Box

Supported platforms

The following platforms support the NCP FSCI Black Box application:

- MCX-W72-EVK
- FRDM-MCXW72

Parent topic:NCP FSCI Black Box

Parent topic:*Bluetooth LE stack and demo applications*

NCP Localization Reader

This section describes the functionality of the NCP Localization Reader demo application.

Description

The BLE NCP Localization Reader application is a demonstration program for the radio core (Core 1) based on the MCUXpresso SDK. This application implements a BLE device that performs distance measurement using Channel Sounding (CS) technology.

The application is designed to work together with the corresponding loc_reader_host application running on the application core (Core 0) in a dual-core architecture.

Core 1 Responsibilities

The device handles all BLE-related operations:

- Connection establishment and management
- Channel Sounding procedure execution
- Service discovery (RAS/BTCS)
- Local and remote CS data collection
- Data fragmentation and transmission to Core 0 via FSCI

Data Transfer to Core 0

The application fragments Channel Sounding measurement data into FSCI-sized messages and transmits them to Core 0 using the following event sequence:

- **gIQLocalTrStart_c**: First fragment with measurement header
- **gIQLocalTrCont_c**: Continuation fragments
- **gIQLocalTrEnd_c**: Final fragment

The same sequence is repeated for remote data (gIQRemoteTrStart_c/Cont_c/End_c).

Each message includes device ID to support multi-peer scenarios.

Parent topic: NCP Localization Reader

Supported platforms

The following platforms support the NCP Localization Reader application:

- MCX-W72-EVK
- FRDM-MCXW72

Over the Air Programming (OTAP)

This section describes the implemented profiles and services, user interactions, and testing methods for the Bluetooth LE OTAP application.

Implemented profile and services

The Bluetooth LE OTAP applications implement the GATT client and server for the custom Bluetooth LE OTAP profile and service.

- **Bluetooth LE OTAP Service** (UUID: 01ff5550-ba5e-f4ee-5ca1-eb1e5e4b1ce0)

The Bluetooth LE OTAP Service is a custom service which has 2 characteristics.

- **OTAP Control Point Characteristic** (UUID: 01ff5551-ba5e-f4ee-5ca1-eb1e5e4b1ce0). This characteristic can be written and indicated to exchange OTAP Commands between the OTAP Server and the OTAP Client. Data chunks are not transferred using this characteristic.
- **OTAP Data Characteristic**(UUID: 01ff5552-ba5e-f4ee-5ca1-eb1e5e4b1ce0). This characteristic can be written without response by the OTAP Server to transfer image file data chunks to the OTAP Client only when an image block transfer is requested via the ATT transfer method. Data chunks can also be transferred via the L2CAP credit-based PSM channels method.

The demo runs using 3 applications: an OTAP Client embedded application, an OTAP Server embedded application, and an Over the Air Programming PC application. The OTAP Client embedded application has two versions, an ATT version and a L2CAP version each using a different transfer method.

The embedded OTAP Server application is a GAP Central application which scans for devices advertising the Bluetooth LE OTAP service. After it finds one, it connects to it and configures the OTAP Control Point CCC Descriptor to receive ATT Indications from the device then it waits for OTAP commands from this device.

Once commands start arriving from the OTAP Client via ATT Indications the OTAP Server relays them via serial interface to a PC application which responds. The responses are then sent back to the OTAP Client by writing the OTAP Control Point Characteristic. The embedded OTAP Server application effectively acts as a relay between the OTAP Client to which the image is sent over the air and the Over the Air Programming PC application which has an OTAP image file constructed using a binary '*.srec*' image or a '*.bin*' image.

The OTAP Client is a GAP Peripheral which advertises the Bluetooth LE OTAP Service and waits for a connection from an OTAP Server. After an OTAP Server connects, the OTAP Client waits for it to write the OTAP Control Point CCCD and then starts sending commands via ATT Indications. If the OTAP Client is configured to ask the data transfer via the L2CAP CoC PSM, it registers and tries to connect a predetermined L2CAP PSM before sending any commands to the OTAP Server.

Parent topic: Over the Air Programming (OTAP)

Supported platforms

The following platforms support the OTAP applications:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK
- FRDM-MCXW23
- MCXW23-EVK
- FRDM-KW43

Parent topic: Over the Air Programming (OTAP)

User interface

After flashing two boards with the OTAP Server and OTAP Client applications respectively, the devices are in Idle mode (all LEDs flashing). To start advertising, press the **ADVSW** button on the OTAP Client. To start scanning, press the **SCANSW** button on the OTAP Server. After the two devices connect and start exchanging commands. **CONNLED** becomes solid on the OTAP Server and on the OTAP Client.

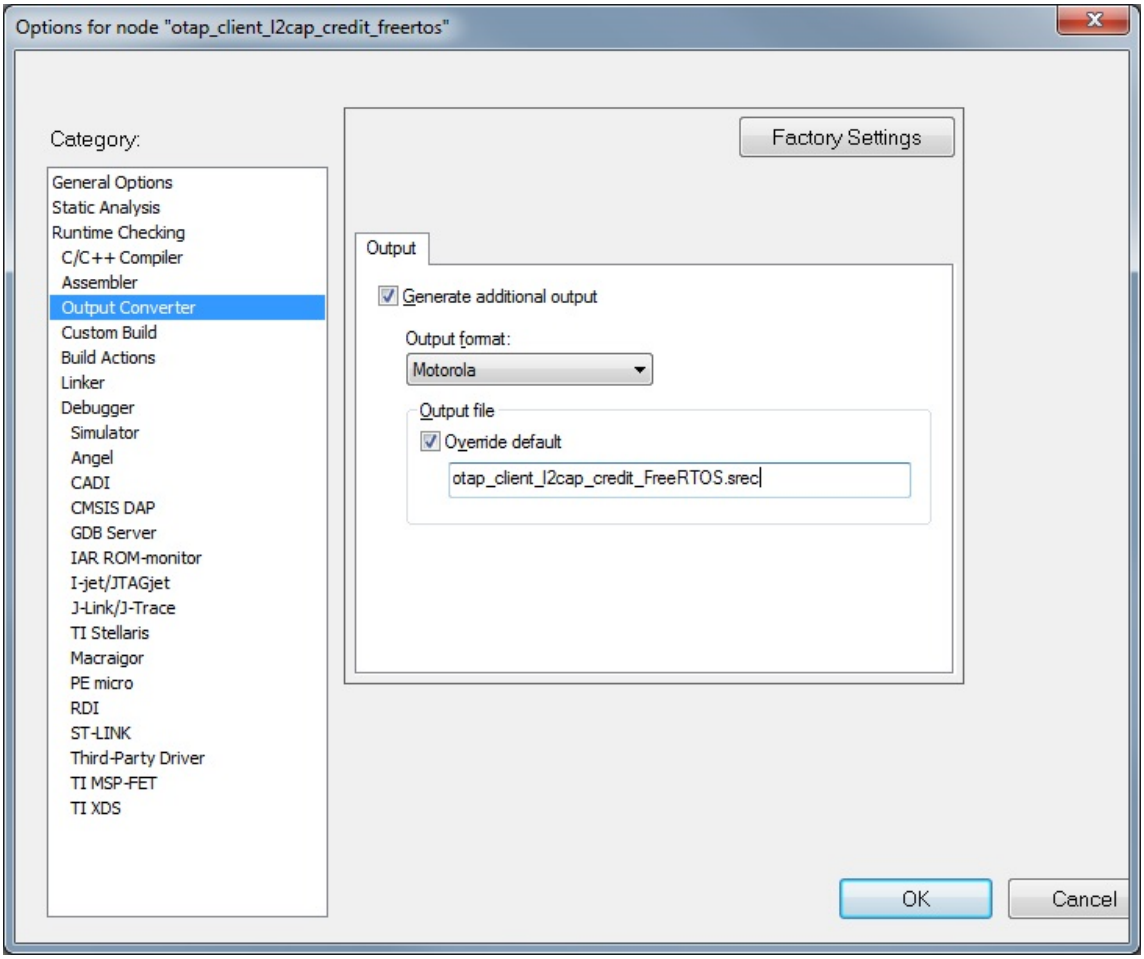
Start the OTAP Server PC application after the embedded applications are flashed to the boards. The application creates an OTAP image file using the provided executable .srec or .bin file. It then connects to the embedded OTAP Server via the configured serial interface and waits for commands. The application shows details about the image file creation and allows the OTAP upgrade image file header to be configured. The log view of the application displays the interactions between the OTAP Client and the OTAP Server.

Parent topic: Over the Air Programming (OTAP)

Switches and pins(Client ATT) Switches and pins(Client L2CAP) Switches and pins(Server)

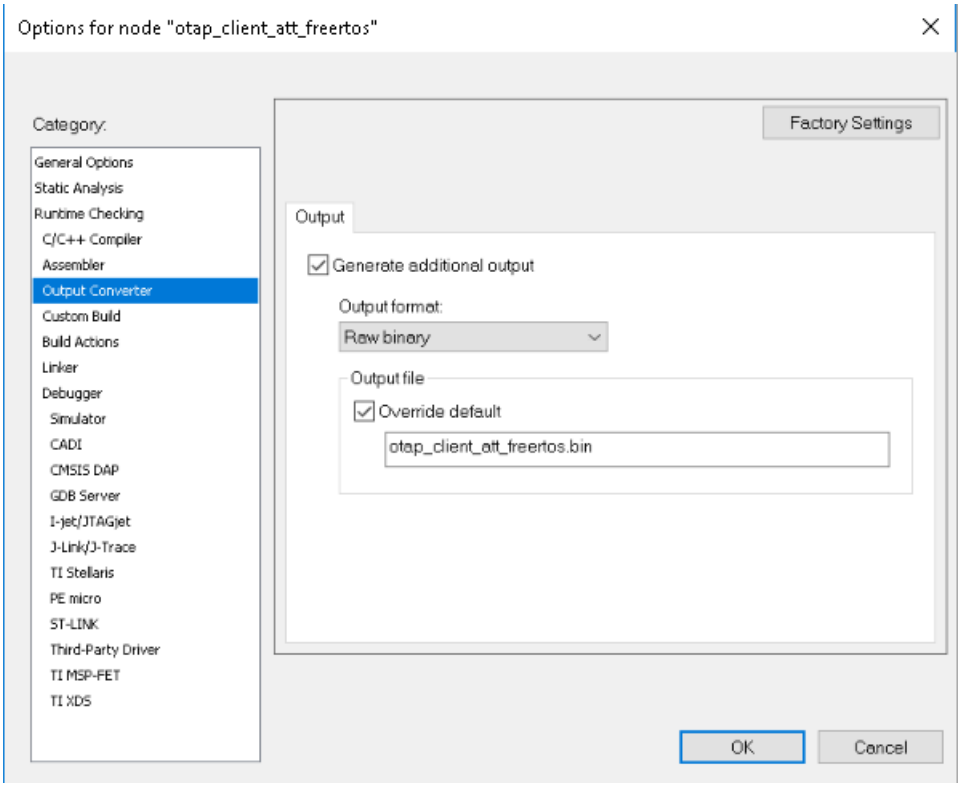
Usage with Over The Air Programming Tool

Below is a list of requirements for usage with Test Tool for Connectivity products:



- Over The Air Programming Tool 1.4.0 or newer on CONNECTIVITY-TOOL-SUITE
- Serial COM port drivers – these are board-specific.

To run the application, follow the steps below:

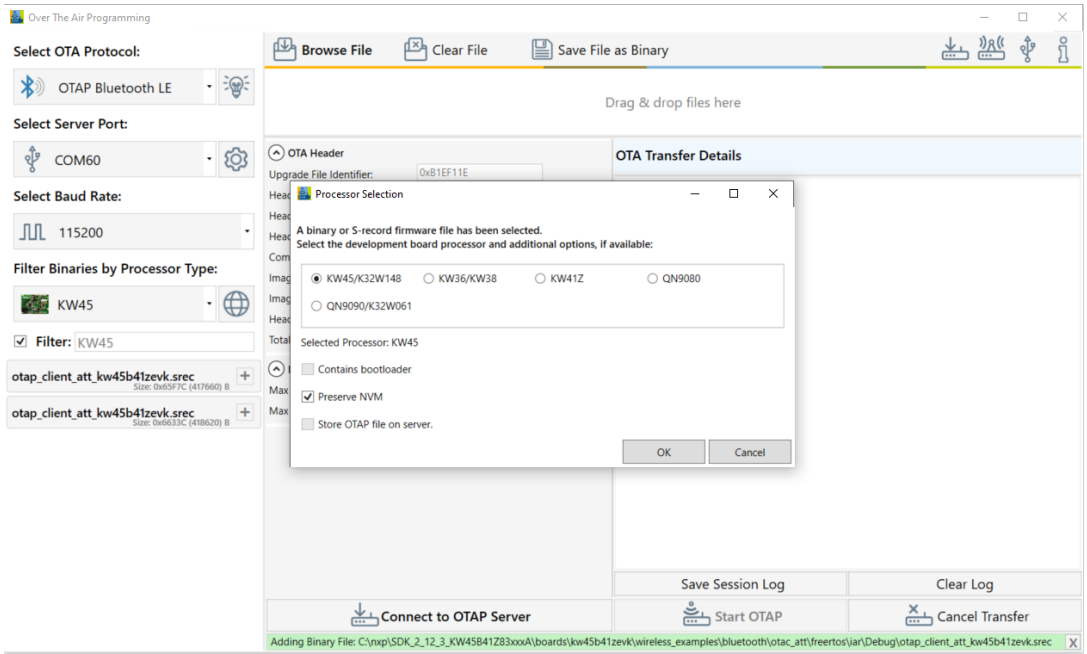


1. Flash the OTAP Server onto a supported platform and the OTAP Client to another supported platform. Make sure the board running the OTAP Server is connected to your PC and your PC has appropriate drivers for the USB to serial device on that board.
2. Create the application to send over the air. The executable must be provided in the .srec or .bin format. The .srec format executable can be obtained by using the IAR Output Converter and setting the output format to Motorola as shown in in the figure below.

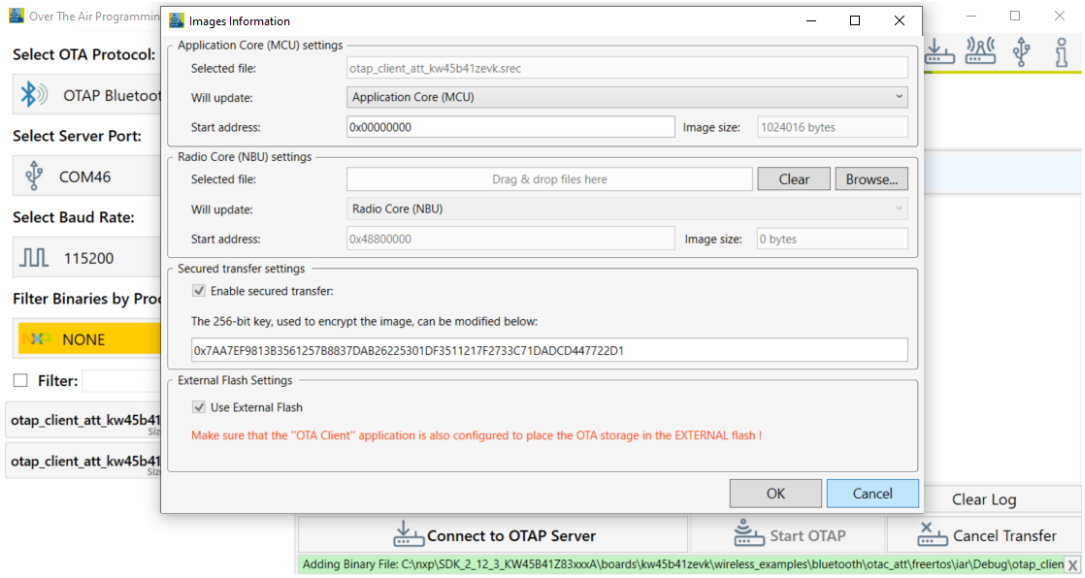
   When compiling an image for the Over-the-Air update, the following changes are required:

   - The gEraseNVMLink_d linker symbol must be set to 0. For GitHub ARMGCC this may be changed in the application reconfig.cmake file.
   - For ARMGCC, gNvmErasePartitionWhenFlashing_c must be set to 0 in app_preinclude.h

3. To obtain a .bin file from IAR, select the **Raw binary** option in the **IAR Output Converter** as seen in the in the figure below.



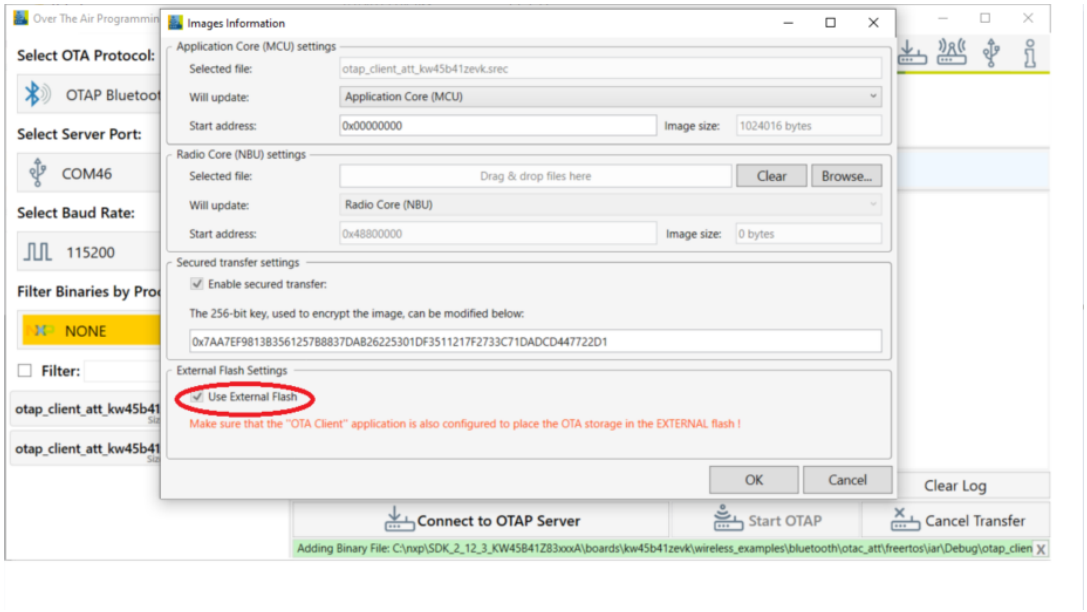
4. Start the **Over The Air Programming** application and select "**OTAP Bluetooth LE**" from the "**Select OTA Protocol**" combo box as shown in the figure below.



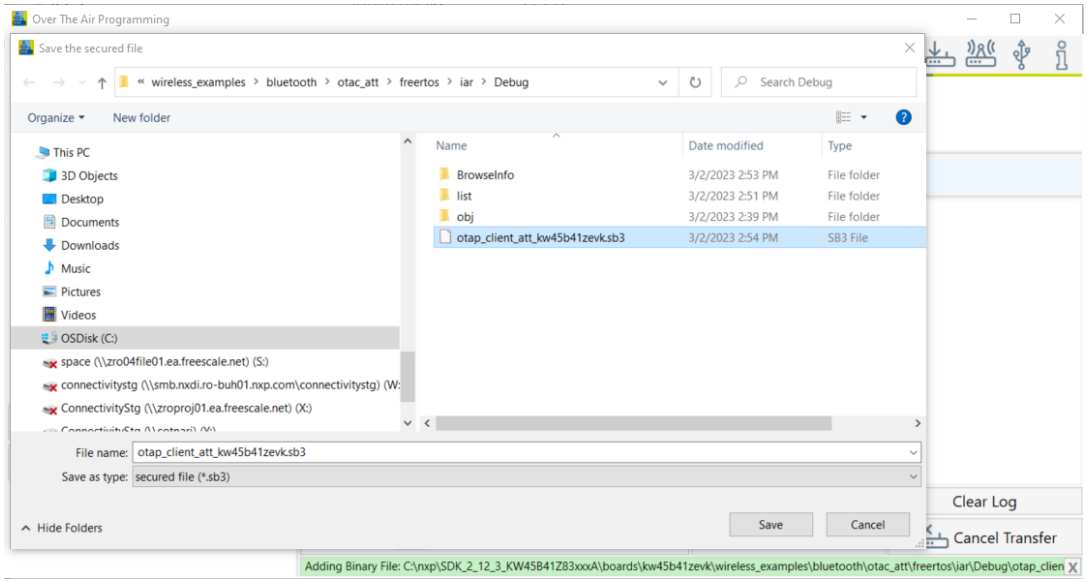
5. **Load the image file into the application, then configure the image file header and start the OTAP Server:**

   - To select the updated image In the Over the Air Programming tool, select the "**Browse File**" button and then navigate to the .srec or .bin file containing the image to be sent to the OTAP Client. After the .srec or .bin file is chosen, a pop-up window asks to choose the target processor. In this example, the **KW45/K32W** processor will be used. Choose the **KW45/K32W** processor and press **OK**. See the figure below.

   - Once the processor is selected, a new pop-up window would appear that allows selecting the type of image as shown in the figure below. (In the specified case, we selected the KW45Z/KW45Z(MCU).



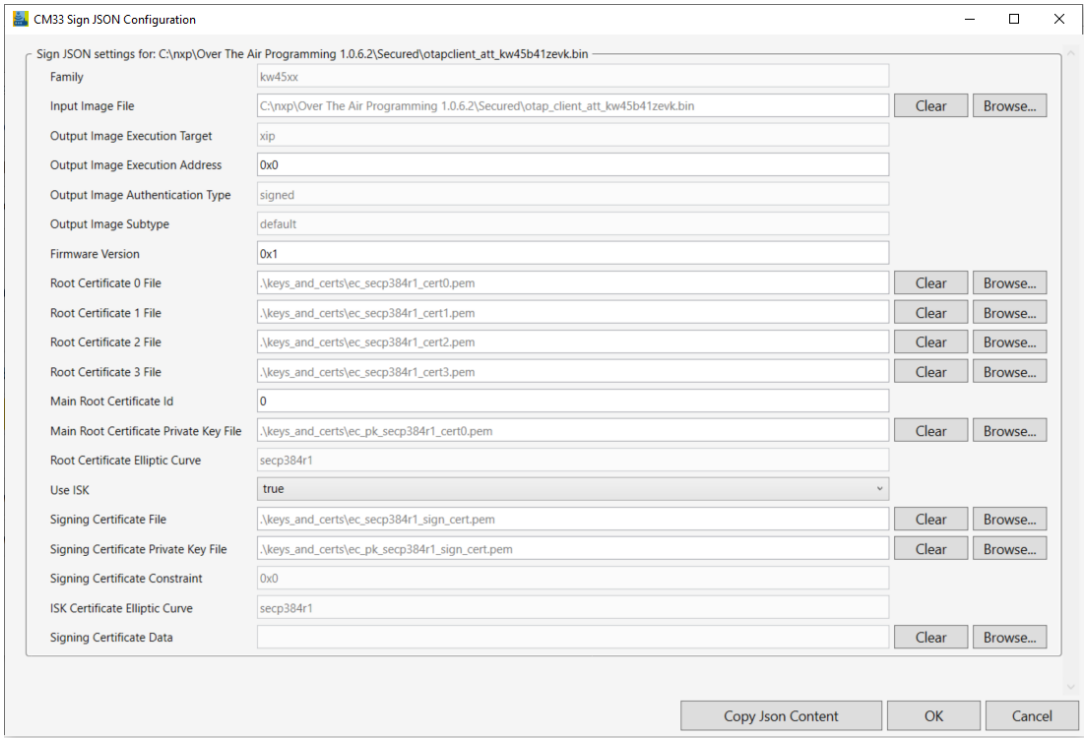
- To update the KW45B/KW32W1 (radio) image, select it by pressing the "**Browse**" button in the M3 group. Then navigate to the .bin file as shown in the figure below.



- If the OTA client has configured external memory support, then "**Use External Flash**" checkbox must be checked as in the figure below. If the OTA client has configured internal memory support, the checkbox must be left unchecked.

  This checkbox (if checked) instructs the OTA client bootloader to erase all the internal storage. This must be done only if external memory support is used as shown in the figure below. .

At this moment, click the **OK**button. A new window appears that prompts you to enter a location where the secured file should be stored. By default, the location of the original file is selected. See the figure below.

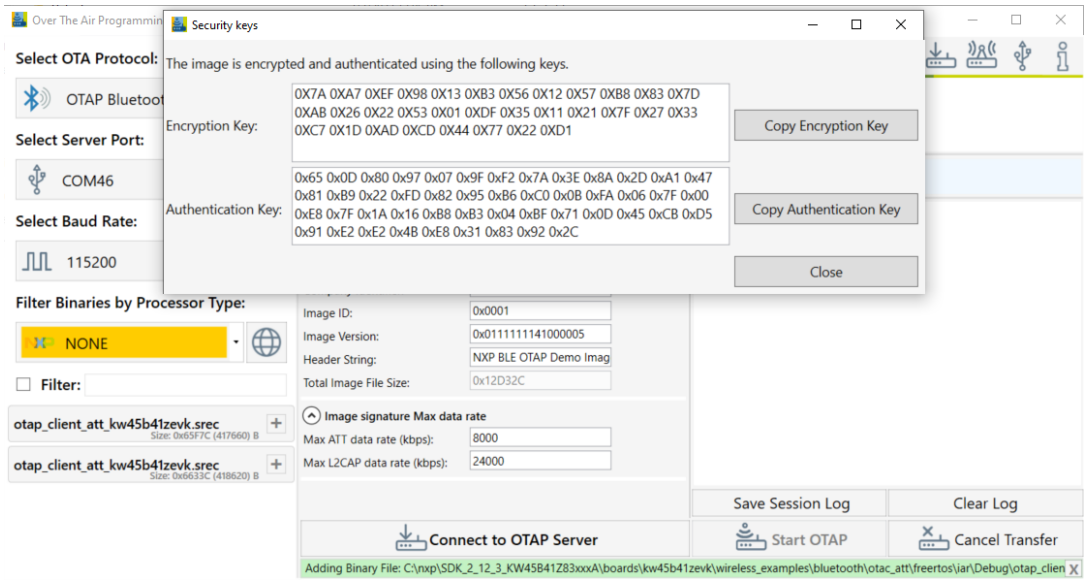


Note: The extension of the secured file is *.sb3. See the figure below.

- You can now configure two different JSON files, used to:
  - Sign the file that is uploaded to the MCU if an MCU file was selected.
  - Create the **.sb3*container that is sent OTA. The **.sb3* file can contain only the MCU file, only the radio file, or both.

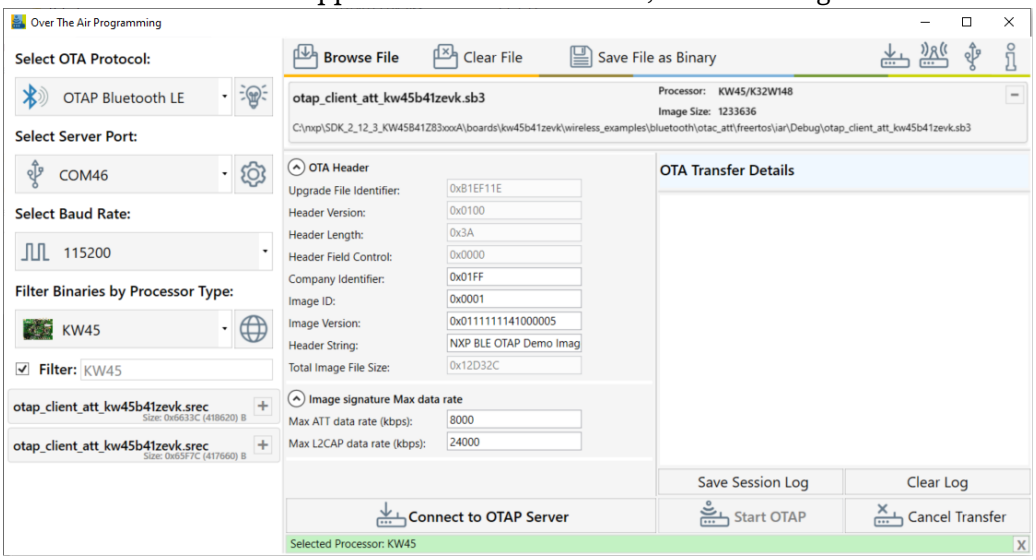
  If you select a file that is written on the MCU, a new window appears as shown in the figure below. This window helps in configuring the root certificates and signing the certificates, by either dragging and dropping, or browsing for new files. For details on each field of the JSON, see */Documentation/KW45JsonDescription.pdf* provided with Over the Air Programming tool.

  By default, the JSON is configured for the demo applications to run as shown in the figure below.



After configuring the JSON file used for signing the MCU file, a new similar window appears. As shown in the Figure, the window is designed for configuring the **.sb3* container. This window helps you to configure the encryption key file, the root certificates, and the signing certificates by either drag and dropping or browsing for new files. For details on each field of the JSON file, see */Documentation/KW45JsonDescription.pdf* provided with Over the Air Programming tool.

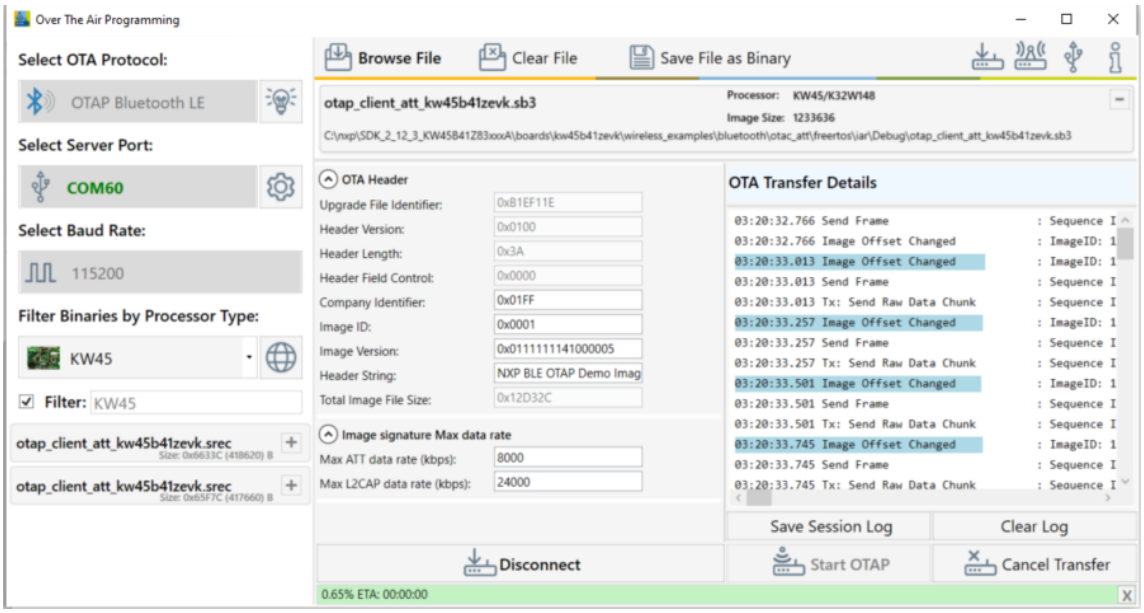
By default, the JSON is configured for the demo applications to run as shown in the figure below.



- After the .sb3 file is created, the "**Encryption Key**" and "**Authentication Key**" are presented. For the secured update to be successful, the destination board must have been

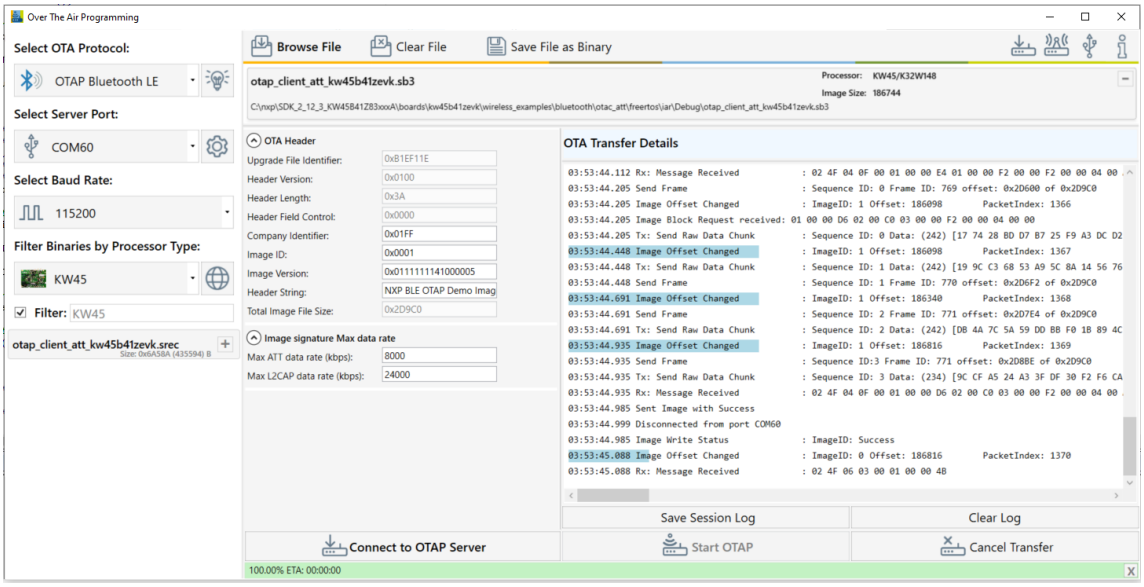
provisioned with these keys through fuse burning, as described in the accompanying document. Depending on the board type, it can either be already provisioned by NXP (KW45\KW47\MCX-W71\MCX-W72\KW43 samples) or not provisioned (loose samples). See the figure below.

- The OTA Header configuration options from the "**OTA Header**" box are used by the application to build the **OTAP Image File**, which is sent over the air. The default values of the OTA Header configuration work out of the box for the OTAP demo applications. For details about these configuration options, see the *Bluetooth LE Application Developer's Guide* document (*BLEADG*).
- After the image is loaded, go to the "**Select Server Port**" box, select the correct COM Port for the OTAP Server board. Also select the default baud rate of 115200 and press the "**Connect to OTAP Server**" button. A successful connection is displayed in the Message Log.
  - If the image is loaded before connecting to the OATP Server COM Port, then the OTAP Server of the application starts automatically.
  - If the connection to the COM Port is established before the image is loaded, then the "**Start OTAP**" button must be pressed to start the OTAP Server of the application. For details, see the figure below. .



- Before starting the image transfer process, the data rate must be configured for each

transfer method (ATT or L2CAP CoC). The image chunks of a block are sent over the serial interface and over-the-air without waiting for confirmation. Data rate can significantly slow down if configuration is not done correctly and errors appear in the transfer process.



The optimal data rate depends on multiple factors. Some of these factors are listed below:

- Distance between boards
- Type of antenna
- Performance of the RF circuitry between the radio and antenna
- Type and level of noise in the environment
- Speed of the storage medium in which the image is saved on the OTAP Client
- Serial driver delay between PC and the OTAP Server board If the data rate is too high, then the OTAP Client receives a new chunk before it can process the previous one. In such a case, it sends an "**Unexpected Chunk Sequence Number**" error and restarts the transfer of the current block from where it left off. If the channel is too noisy, the transmitter can be flooded and some chunks might not reach the client triggering a similar type of error. The default data rate values should work for most configurations.

6. Start the embedded applications by pressing **ADVSW** first on the OTAP Client and then on the OTAP Server. The transfer progress and transfer-related messages and/or errors are shown in the application window. The duration of the transfer depends on the size of the image and the chosen data rate and transfer method. See the figure below.

7. After all the blocks are sent, the OTAP Client sends an Image Transfer Complete command to the OTAP Server. When the PC Application receives this command, it displays a Sent Image with Success message in the log window. See the figure below.

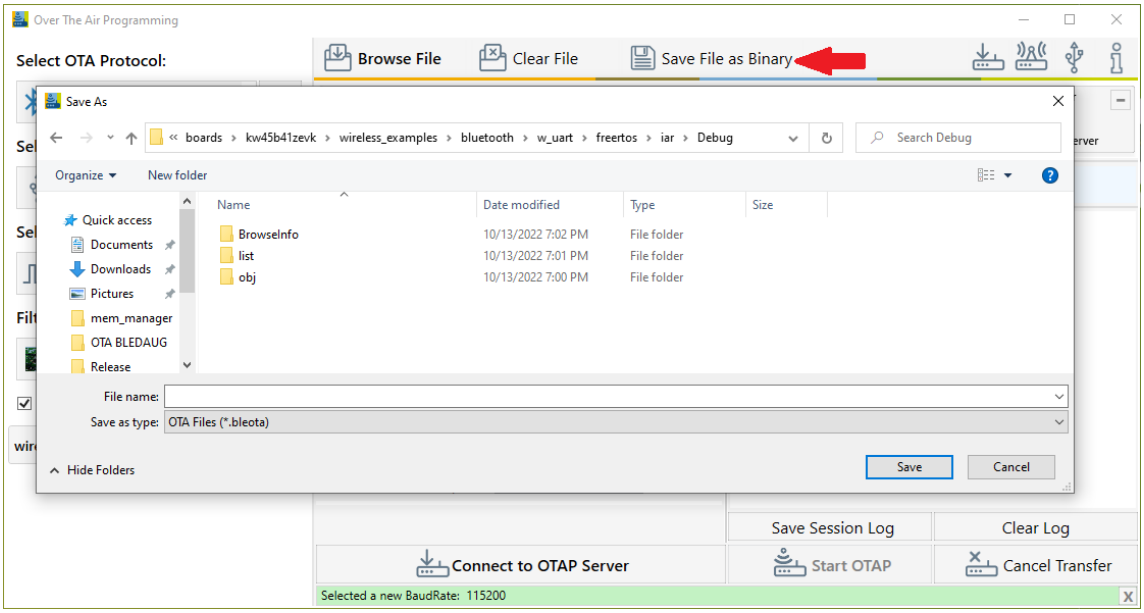
8. After the image transfer is complete, the OTAP Client triggers the bootloader and resets the MCU. The bootloader takes about 30 seconds to flash the image on the board. After this time frame, the MCU resets again and runs the new image.

Parent topic: Over the Air Programming (OTAP)

Storage type selection

OTAP Clients support both internal and external storage. By default, the applications come with internal storage enabled. To configure external storage, follow the steps bellow:

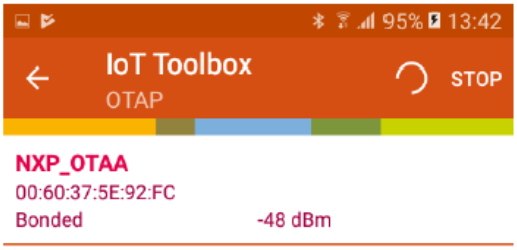
1. Set the gUseInternalStorageLink_d define to 0 in the project settings. For GitHub AR-MGCC, replace CONFIG_MCUX_COMPONENT_middleware.wireless.framework.ota_support.no_flash_selected=y with CONFIG_MCUX_COMPONENT_middleware.wireless.framework.ota_support.external_flash=y in the application prj.conf file.
2. In app_preinclude.h, set the gAppOtaExternalStorage_c define to 1.



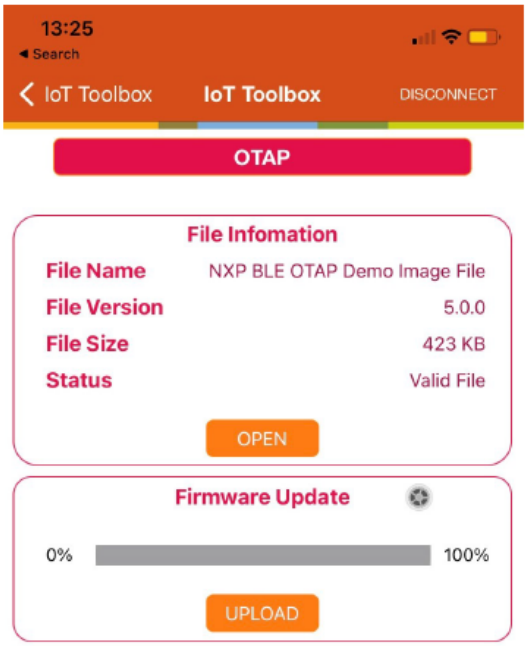
Usage with IoT Toolbox

This is the list of requirements.

- **Mobile device** running **Android** platform or **iOS** with hardware and software supporting **Bluetooth 4.0 and later**.
- **Kinetis Bluetooth LE Toolbox** application – download from the specific application store for your device.

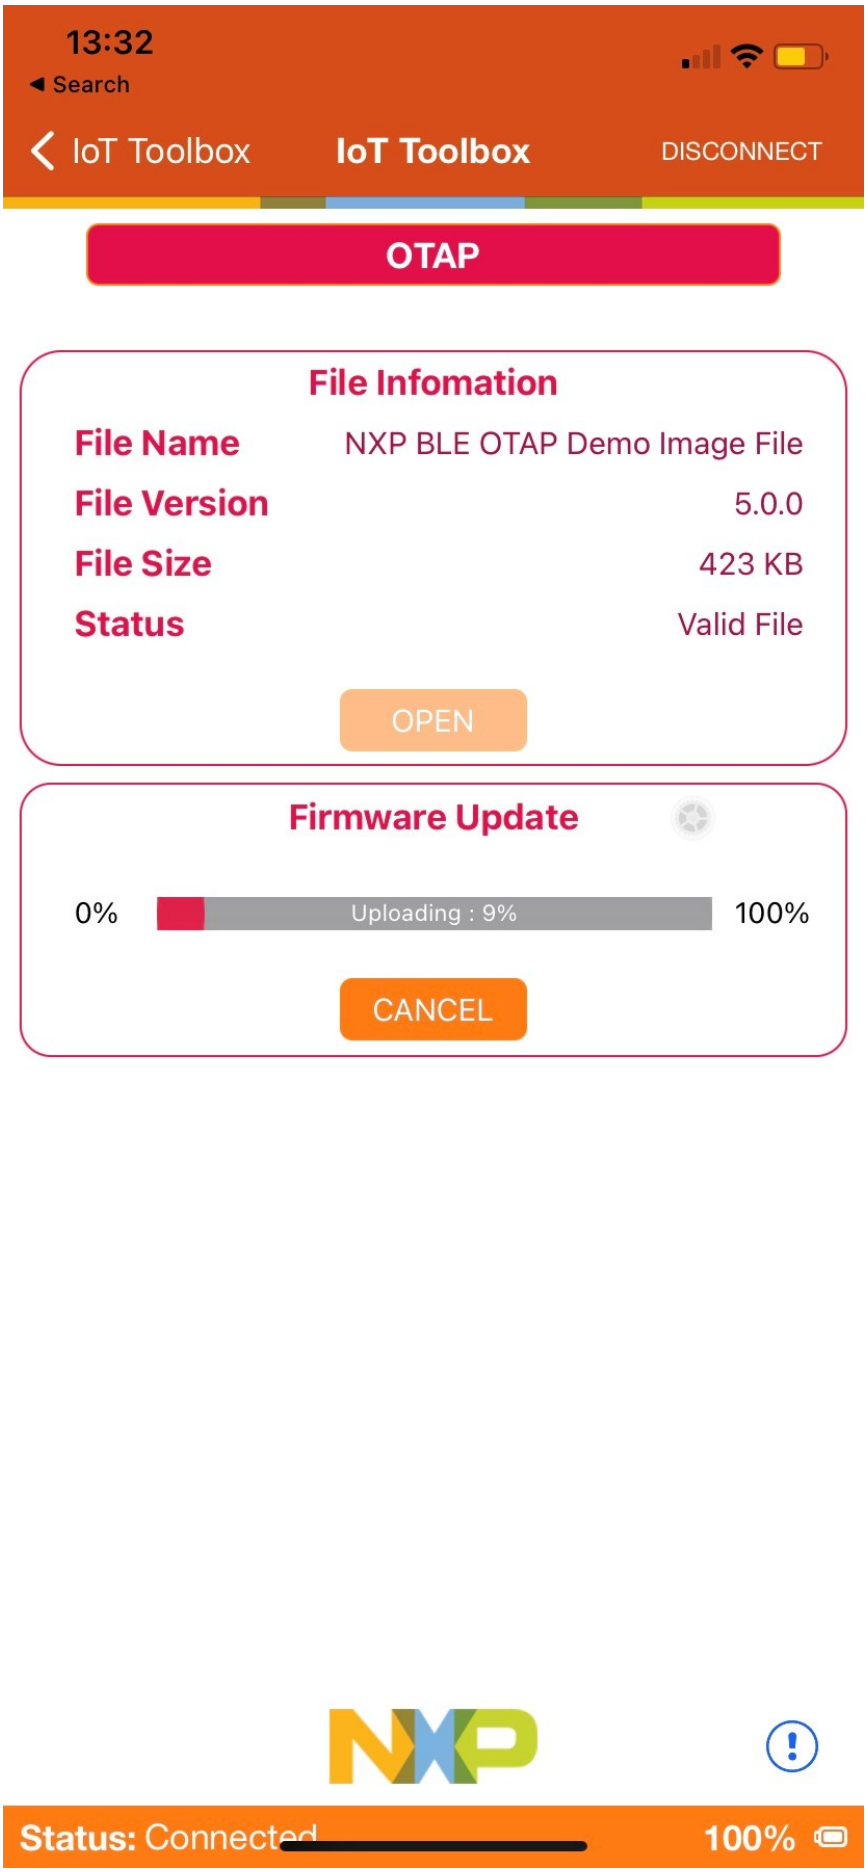


To run the application, perform the following steps:



1. Flash the OTAP Client ATT to either the KW45B41Z-EVK or the FRDM-MCXW71 platform. The Kinetis Bluetooth LE Toolbox only supports the ATT OTAP Client.
2. In order to send over the air in .bleota format, create the application. In order to load the image file into the Over the Air Programming application and create the .sb3 file, follow the instructions described in Usage with Over The Air Programming Tool. Once the .sb3 file is created, press the "**Save File as Binary**" button to create the .bleota file. See the figure below.

3. Start the **Kinetis Bluetooth LE Toolbox**application on your mobile device and start the **OTAP Tool**. The application starts scanning.



4. Press **ADVSW** on the board to start Advertising on the embedded OTAP Client application. The device should show up in the list of scanned devices. Touch the device in the scan list to connect to and the application performs service discovery and displays some information shown in the figure below.

5. Press the “**Open**” button and load the .bleota file to be sent over-the-air. Once the file is loaded, some information about it is displayed. Press the “**Upload**” button to start the image

transfer process. A progress bar is shown while the image transfer is ongoing. The progress bar displays 100% update after a successful transfer, as shown in the figure below.

6. After the image transfer is complete, the OTAP Client triggers the bootloader and resets the MCU. The bootloader takes about 30 seconds to flash the image on the board. After this time passes, the MCU resets again and runs the new image.

Parent topic: Over the Air Programming (OTAP)

Parent topic:*Bluetooth LE stack and demo applications*

Wireless UART

This section describes the implemented profiles and services, user interactions, and testing methods for the Wireless UART application.

Implemented profile and services

The Wireless UART application implements both the GATT client and server for the custom Wireless UART profile and services.

- Wireless UART Service (UUID: 01ff0100-ba5e-f4ee-5ca1-eb1e5e4b1ce0)
- Battery Service v1.0
- Device Information Service v1.1

The Wireless UART service is a custom service that implements a custom writable ASCII Char characteristic (UUID: 01ff0101-ba5e-f4ee-5ca1-eb1e5e4b1ce0) that holds the character written by the peer device.

The application behaves at first as a GAP central node. It enters GAP Limited Discovery Procedure and searches for other Wireless UART devices to connect. To change the device role to GAP peripheral, use the ROLESW button. The device enters GAP General Discoverable Mode and waits for a GAP central node to connect.

Parent topic: Wireless UART

Supported platforms

The following platforms support the Wireless UART application:

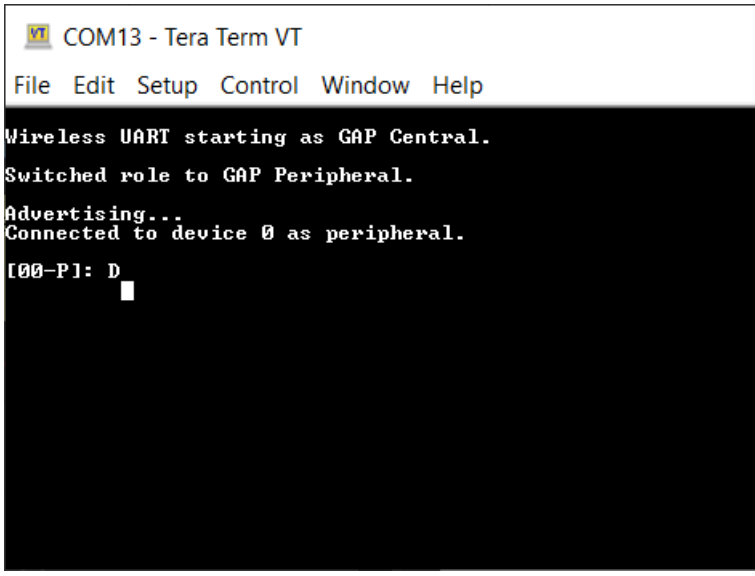
- KW45B41Z-EVK
- KW45B41Z-LOC
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- KW47-LOC
- KW43-LOC
- FRDM-MCXW72
- MCX-W72-EVK
- MCXW72-LOC
- FRDM-MCXW23
- MCXW23-EVK
- FRDM-KW43

Parent topic: Wireless UART

User interface

After flashing the board, the device is in idle mode (all LEDs flashing). To start scanning, press the **SCANSW** button. When in GAP Limited Discovery Procedure of GAP General Discoverable Mode, **CONNLED** is flashing. When the node connects to a peer device, **CONNLED** turns solid. To disconnect the node, hold the **SCANSW** button pressed for 2-3 seconds. The node then re-enters GAP Limited Discovery Procedure.

Parent topic: Wireless UART



Switches and pins

Usage

The application is built to work with another supported platform running the same example or with the Wireless UART from the IoT Toolbox application.

When testing with two boards, perform the following steps:

1. Open a serial port terminal and connect them to the two boards, in the same manner described in Testing devices. The start screen is blank after the board is reset.
2. The application starts as a GAP central. To switch the role to a GAP peripheral, press the role switch. Depending on the role, when pressing the **SCANSW**, the application starts either scanning or advertising.
3. As soon as the **CONNLED** turns solid on both devices, the user can start writing in one of the consoles. The text appears on the other terminal.
4. After creating a connection, the role (central or peripheral) is displayed on the console. The role switch can be pressed again before creating a new connection. See the figure below.

Tera Term – received text on Wireless UART

When testing with a single board and the IoT Toolbox, perform the following steps:

1. Open a serial port terminal and connect the board in the same manner described in Testing devices. The start screen is blank after the board is reset.
2. Press the role switch button to behave as a GAP peripheral and then press the **SCANSW** button to start advertising. The IoT Toolbox app can then connect. Select UART instead of Console and start typing, as shown in the Figure.

Parent topic: Wireless UART

Out of band GATT Client

The application supports setting the required GATT client handles, thus avoiding service discovery after each connection. The method for obtaining the service handles is out of the scope of this example. To activate this feature, user must set gDbOobPopulated_c to 1. The required handles are the Wireless UART Service handle (expressed as gDbOobServiceHandle_c) and the UART stream service handle (expressed as gDbOobUartStreamHandle_c). When gDbOobPopulated_c is set, these two macros must be also set with corect values reflecting Server's handles.

Parent topic:*Bluetooth LE stack and demo applications*

Bluetooth LE Shell

This section describes the functionality, user interactions, and testing methods for the Bluetooth LE Shell Application.

Implemented stack features

The Bluetooth LE Shell Application implements a console application that allows the user to interact with a full feature Bluetooth Low Energy stack library. It implements All GAP roles and both GATT client and server. Enabling these roles can be done using shell commands.

Parent topic: Bluetooth LE Shell

Implemented profile and services

The application implements a dynamic GATT database. The user can add services at runtime and also erase the database contents. The database is always populated with the GAP and GATT services. These services cannot be erased. The user can dynamically add the following services:

- Heart Rate Service (UUID: 0x180D)
- Battery Service (UUID: 0x180F)
- Device Information Service (UUID: 0x180A)
- Internet Support Profile Service (0x1820)

Parent topic: Bluetooth LE Shell

Supported platforms

The following platforms support the Bluetooth LE Shell application:

- KW45B41Z-EVK
- FRDM-MCXW71
- MCX-W71-EVK
- KW47-EVK
- FRDM-MCXW72
- MCX-W72-EVK
- FRDM-KW43

Parent topic: Bluetooth LE Shell

User interface

After flashing the board, the device is in idle mode. The interaction with the board is done entirely by using the shell commands via the serial communication terminal.

Parent topic: Bluetooth LE Shell

Usage

The application is built to work with any other Bluetooth LE device. To showcase the functionality, two platforms are used in the following setup.

1. Open a serial port terminal and connect them to the two boards, in the same manner described in Testing devices. The start screen is displayed after the board is reset. All LEDs are flashing on both devices.
2. Configure one of the devices as a GAP peripheral and a Heart Rate server. Change name to HRS. Start advertising on this device.

```
BLE Shell>gap devicename HRS
--> GATTDB Event: Attribute Written
HRS>gap advdata 1 6
HRS>gap advdata 8 HRS
HRS>gap advstart
HRS>
--> GAP Event: Advertising parameters successfully set.
HRS>
--> GAP Event: Advertising data successfully set.
HRS>
--> GAP Event: Advertising state changed successfully!
HRS>gattdb addservice 0x180D
--> Heart Rate
- Heart Rate Measurement Value Handle: 14
```

3. Configure the other device as a GAP central. Change its name to 'Collector'. Start scanning and connect to the HRS device by selecting the corresponding device index from the list of scanned devices. In the example below, the HRS device is device number 2. The number of listed scanned devices can be controller through the mShellGapMaxScannedDevicesCount_c define in shell_gap.c.

```
BLE Shell>gap devicename Collector
--> GATTDB Event: Attribute Written
Collector>gap scanstart filter
--> GAP Event: Scan started.
Collector>
--> GAP Event: Found device 0 : 880F102F500E 0 dBm
--> GAP Event: Found device 1 : NXP_CSCS 00049F000006 0 dBm
--> GAP Event: Found device 2 : HRS 00049F0000FF 0 dBm
Collector>gap connect 2
--> GAP Event: Scan stopped.
Collector>
--> GAP Event: Connected to peer 0
```

4. Optionally, the devices can be paired (gAppUsePairing_d and gAppUseBonding_d must be set in app_preinclude.h). On the collector initiate the pairing.

```
Collector>gap pair 0
--> Pairing...
--> GAP Event: Link Encrypted
--> GAP Event: Device Paired
```

5. On the Collector, start service discovery. The device discovers the GAP, GATT, and Heart Rate services.

```
Collector>gatt discover 0 -all
--> Discovered primary services: 3
--> Generic Attribute Start Handle: 1 End Handle: 4
- Service Changed Value Handle: 3
- Client Characteristic Configuration Descriptor Handle: 4
--> Generic Access Start Handle: 5 End Handle: 11
```

(continues on next page)

(continued from previous page)

```
- Device Name Value Handle: 7
- Appearance Value Handle: 9
- Peripheral Preferred Connection Parameters Value Handle: 11
--> Heart Rate Start Handle: 12 End Handle: 19
- Heart Rate Measurement Value Handle: 14
- Client Characteristic Configuration Descriptor Handle: 15
- Body Sensor Location Value Handle: 17
- Heart Rate Control Point Value Handle: 19
```

6. Configure the HRS to send notifications by writing the CCCD from the Collector. Send a GATT write command with value 1 to the CCCD handle discovered, 15.

```
Collector>gatt write 0 15 0x0001
--> GATT Event: Characteristic Value Written!
```

7. Send heart rate measurement notifications from the HRS device by using the value handle obtained after adding the service in the previous step.

```
HRS>gatt notify 0 14
```

8. A notification appears on the Collector console.

```
Collector>
--> GATT Event: Received Notification
Handle: 14
Value: B400
```

Extended advertising

Use the Bluetooth LE Shell application to exercise the advertising extension features:

On the GAP Peripheral device:

1. Configure the extended advertising parameters. In the below example, the advertising type is set to connectable and includes TX power and the primary PHY is set to Coded PHY.
2. Configure the extended advertising data. The Bluetooth LE Shell applications has the feature to send for test, a large data payload. Use the extended advertisement default configuration (not call "gap extadvcfg"), pass the command "gap extadvdata" with no parameters and the default data is added. The length is configurable at compile time through SHELL_EXT_ADV_DATA_SIZE and the data pattern is SHELL_EXT_ADV_DATA_PATTERN. Start the default test with call for "gap extadvstart".

   The advertising data type is set to shortened local name (8) and the advertising data content is set to test_ext_adv_data.

   Note: Users must note that extended connectable advertising does not allow for chained advertising data. The data length must be limited to what can fit in a single AUX_ADV_IND PDU (251 bytes at maximum). This means that passing the gap extadvdata with no parameters and the default value of SHELL_EXT_ADV_DATA_SIZE (500 bytes) after having set the advertising type to connectable will result in an error when trying to start advertising.
3. Start extended advertising.

```
BLE Shell>gap extadvcfg -type 65 -phy1 3
BLE Shell>gap extadvdata 8 test_ext_adv_data
BLE Shell>gap extadvstart
--> GAP Event: Extended
Advertising parameters successfully set.
--> GAP Event:
Extended Advertising data successfully set.
--> GAP Event: Advertising state changed successfully!
```

4. **On the GAP Central device**

   Set the scanning parameters. The scanning PHY is set to match the advertising PHY, in this case Coded PHY.

5. Start scanning and filter duplicates.

```
BLE Shell>gap scancfg -phy 4
BLE Shell>gap scanstart filter
BLE Shell>
-> GAP Event: Scan started.
BLE Shell>
--> GAP Event: Found device 0 : 0060375BCEC6 -23 dBm
Advertising Extended Data:
test_ext_adv_data
```

6. Set the connection initiating PHYs corresponding to the primary PHY on which the advertising is performed.

7. Connect to the desired device in the scanned devices list.

```
BLE Shell>gap connectcfg -phy 4
--> Connection Parameters:
--> Connection Interval: 200 ms
--> Connection Latency: 0
--> Supervision Timeout: 32000 ms
--> Connecting PHYs: Coded
BLE Shell>gap connect 0
BLE Shell>
-> GAP Event: Scan stopped.
BLE Shell>
--> GAP Event: Connected to peer 0
```

Parent topic: Usage

RSSI Monitor

RSSI Monitor is an application that allows monitoring the RSSI of a remote peer on advertising or connection channel. The GAP peripheral device can modify the output TX power on both advertising and connection channels.

1. **On GAP peripheral device**

   Set the primary advertising PHY to Coded PHY. Start advertising and read the address. Set the TX power in dBm to a value less than 20 dBm.

```
BLE Shell>gap address
BLE Shell>
--> GAP Event: Public Address:C4603770BCC5
BLE Shell>gap extadvcfg -phy1 3
BLE Shell>gap extadvstart
BLE Shell>
--> GAP Event: Extended Advertising parameters successfully set.
BLE Shell>
--> GAP Event: Extended Advertising data successfully set.
BLE Shell>
--> GAP Event: Advertising state changed successfully!
BLE Shell>gap txpower adv 0
BLE Shell>
--> GAP Event: Success!
```

2. **On GAP Central device**

   Set the scanning PHY to Coded PHY. Start monitoring the RSSI on advertising Channel using the address of the Peripheral device. Scanning starts automatically, if it is not previously

enabled.

```
BLE Shell>gap scancfg -phy 4
BLE Shell>gap rssimonitor C4603770BCC5--> Reading RSSI on advertising channel:
BLE Shell>
-> GAP Event: Scan started.
BLE Shell>
 RSSI: -27 dBm
 RSSI: -27 dBm
 RSSI: -27 dBm
 RSSI: -27 dBm
 RSSI: -27 dBm
 RSSI: -29 dBm
```

In the below example, the RSSI in monitored on a connection channel. On GAP Peripheral, start advertising in connectable mode on Coded PHY and adjust the TX power level.

```
BLE Shell>gap extadvcfg -type 65 -phy1 3
BLE Shell>gap extadvdata 8 rssimonitortest
BLE Shell>gap extadvstart
BLE Shell>
--> GAP Event: Extended Advertising parameters successfully set.
BLE Shell>
--> GAP Event: Extended Advertising data successfully set.
BLE Shell>
--> GAP Event: Advertising state changed successfully!
BLE Shell>
--> GAP Event: Connected to peer 0
BLE Shell>
--> GAP Event: Advertising stopped!
BLE Shell>gap txpower conn 10
BLE Shell>
--> GAP Event: Success!
```

On the GAP Central device, start scanning on the Coded PHY. Update the connection PHY also to Coded PHY, then connect to the remote device and monitor continuously the RSSI on the connection channel.

```
BLE Shell>gap scancfg -phy 4
BLE Shell>gap connectcfg -phy 4
-->  Connection Parameters:
    -->  Connection Interval: 200 ms
    -->  Connection Latency: 0
    -->  Supervision Timeout: 32000 ms
    -->  Connecting PHYs: Coded
BLE Shell>gap scanstart filter
BLE Shell>
->  GAP Event: Scan started.
BLE Shell>
-->  GAP Event: Found device 0 : C4603770BCC5 -21 dBm
 Advertising Extended Data:
rssimonitortest
gap connect 0
BLE Shell>
->  GAP Event: Scan stopped.
BLE Shell>
-->  GAP Event: Connected to peer 0
BLE Shell>gap rssimonitor 0 -c
-->  Reading RSSI from connected device:
BLE Shell>
 RSSI: -22 dBm
```

(continues on next page)

(continued from previous page)

```
 RSSI: -23 dBm
 RSSI: -21 dBm
 RSSI: -22 dBm
 RSSI: -22 dBm
BLE Shell>gap rssistop
```

3. Update the PHY preference and continue monitoring the RSSI. For coded PHY, the coding scheme can be configured between S2 and S8 (500 kbit/s and 125 kbit/s).

```
BLE Shell>gap phy 0 -tx 4 -rx 4 -o 1
BLE Shell>
--> GAP Event: Phy update complete with peer 0
--> TxPhy: Coded
--> RxPhy: Coded

BLE Shell>gap phy 0 -tx 2 -rx 2
BLE Shell>
--> GAP Event: Phy update complete with peer 0
--> TxPhy: 2M
--> RxPhy: 2M

BLE Shell>gap rssimonitor 0 -c
--> Reading RSSI from connected device:
BLE Shell>
RSSI: -23 dBm
RSSI: -23 dBm
RSSI: -21 dBm
RSSI: -21 dBm
--> GAP Event: Phy update complete with peer 0
--> TxPhy: Coded
--> RxPhy: Coded

BLE Shell>
RSSI: -22 dBm
RSSI: -21 dBm
RSSI: -22 dBm
RSSI: -23 dBm
RSSI: -23 dBm
--> GAP Event: Phy update complete with peer 0
--> TxPhy: 2M
--> RxPhy: 2M
BLE Shell>
RSSI: -22 dBm
RSSI: -21 dBm
RSSI: -21 dBm
RSSI: -20 dBm
```

Parent topic: Usage

Transient Application Key

Use the Bluetooth LE Shell application to exercise the TAK(Transient Application Key) feature. First, 'gAppUseTAK_d' must be enabled and 'gConnTakMaxEntries_c' must be configured to the maximum number of keys we want to support on a device. Also 'gBleHostAutoRejectLtkRequestForUnbondedDevices_c' must be set to FALSE in case the device is peripheral. The key is stored per device ID. The device ID is obtained after connection. Each key is erased after it is used, as per TAK specification requirements.

On the GAP Peripheral device:

1. Configure the extended advertising data to include TAK identifier and set the TAK key for the desired device.

The advertising data type is set to shortened local name (8) and the advertising data content is set to TAK_ID.

2. Start extended advertising.

```
BLE Shell>gap extadvdata 8 TAK_ID
BLE Shell>gap extadvstart
--> GAP Event: Extended
Advertising parameters successfully set.
--> GAP Event:
Extended Advertising data successfully set.
--> GAP Event: Advertising state changed successfully!
...
--> GAP Event: Connected to peer 0
BLE Shell>gap tak 0 00112233445566778899aabbccddeeff
```

3. **On the GAP Central device**

   Set the scanning parameters.

4. Start scanning.

```
BLE Shell>gap scanstart
BLE Shell>
-> GAP Event: Scan started.
BLE Shell>
--> GAP Event: Found device 0 : 0060375BCEC6 -23 dBm
Advertising Extended Data:
TAK_ID
...
BLE Shell>gap tak 0 00112233445566778899aabbccddeeff
```

5. Connect to the desired device in the scanned devices list.

```
BLE Shell>gap connect 0
BLE Shell>
-> GAP Event: Scan stopped.
BLE Shell>
--> GAP Event: Connected to peer 0
```

Parent topic: Usage

Parent topic: Bluetooth LE Shell

Throughput feature

The Bluetooth LE Shell application also has a throughput test feature that can be used to test different combinations of the parameters (connection interval, payload size, and packet count) to determine the best data-rate.

This feature requires two devices:

- GAP Peripheral: transmits the test packets
- GAP Central: receives the packets and displays a report

All throughput-related commands are grouped under the **thrput** keyword:

- thrput setparam: configures connection interval, packet count and payload size.
- thrput start tx: configures the device as a GAP Peripheral and starts advertising. Once the receiving device is connected, the packet transmission begins. The packet size and count can also be specified (-s<size_value>-c<count_value>).
- thrput start rx: configures the device as a GAP Central and starts scanning. Once a transmitter device is found, it connects to it and waits for the test to begin. The connection interval can also be configured (-ci<value>).

- thrput stop: stops the test and disconnects the devices.

Once a connection is established between the devices and initial throughput test is complete, one can start a new throughput transmission test with a new set of parameters (packet size / count).

The receiving device generates the report if no packets are received for more than three consecutive connection events.

The default configuration of the throughput test is the following:

- Packet count: 1000
- Payload size: 20 bytes

Connection interval (min, max): 160, 160 (200 ms)

The example of a test report is shown below:

```
BLE Shell>thrput start tx
BLE Shell>
--> GAP Event: Advertising parameters successfully set.
BLE Shell>
--> GAP Event: Advertising data successfully set.
BLE Shell>
--> GAP Event: Advertising started.

Parent topic: Bluetooth LE Shell

Decision-Based Advertising Filtering (DBAF) feature

The Bluetooth LE Shell application also supports the Decision-Based Advertising Filtering (DBAF) feature, which can be enabled by performing the following steps:

- In app_preinclude.h file, set BLE_SHELL_DBAF_SUPPORT to 1.

This feature requires two devices:

- GAP Peripheral: transmits decision PDUs (ADV_DECISION_IND).
- GAP Central: scans for decision PDUs and handles filtering policies.

To showcase the functionality, two platforms are used in the following setup.

Steps to perform on the GAP Peripheral device:

1. Configure the extended advertising parameters to use decision PDUs. In the below example, the advertising type is set to connectable and includes TX power, uses decision PDUs and includes AdvA in the decision PDU. The primary PHY is set to Coded PHY.
2. Configure the extended advertising data using the gap extadvdecdata command. The resolvable tag and/or arbitrary data can be set using the parameters available.
3. Start extended advertising.

```
BLE Shell>gap extadvcfg -phy1 3 -type 449
BLE Shell>gap extadvdecdata -key 112233445566778899AABBCCDDEEFF00 -prand 5AC317 -decdata␣
↪6362 -datalen 2 -restag 0
BLE Shell>gap extadvstart
BLE Shell>
--> GAP Event: Extended Advertising parameters successfully set.
BLE Shell>
--> GAP Event: Extended Advertising data successfully set.
BLE Shell>
--> GAP Event: Extended Advertising Decision Data Setup Complete.
BLE Shell>
--> GAP Event: Advertising state changed successfully!
BLE Shell>
```

Steps to perform on the GAP Central device:

1. Set the scanning parameters to scan only decision PDUs. The scanning PHY is set to match the advertising PHY, in this case Coded PHY.
2. Set the connection parameters to use only decision PDUs and the connection initiating PHYs corresponding to the primary PHY on which the advertising is performed.

```
BLE Shell>gap scancfg -phy 4 -filter 12
BLE Shell>gap connectcfg -phy 4 -filter 2
--> Connection Parameters:
 --> Connection Interval: 200 ms
 --> Connection Latency: 0
 --> Supervision Timeout: 32000 ms
 --> Connecting PHYs: Coded
 --> Connection Filter Policy: 2
BLE Shell>
```

3. Add decision instructions using the gap adddecinstr command. A maximum of gMaxNumDecisionInstructions_c instructions can be added. If the set of instructions must be changed, the gap deldecinstr command deletes all current instructions.

```
BLE Shell>gap adddecinstr -group 1 -field 0 -criteria 1 -restagkey␣
↪112233445566778899AABBCCDDEEFF00
BLE Shell>gap adddecinstr -group 1 -field 6 -criteria 1 -advmode 6
BLE Shell>gap adddecinstr -group 0 -field 24 -criteria 1 -arbmask 00000000ffffff
BLE Shell>gap adddecinstr -group 0 -field 9 -criteria 1 -advacheck 2 -add1type 0 -add1 a6fb0d376000 -
↪add2type 0 -add2 a5fb0d376000
BLE Shell>gap adddecinstr -group 0 -field 7 -criteria 1 -rssimin -80 -rssimax 0
BLE Shell>gap adddecinstr -group 0 -field 8 -criteria 5 -lossmin 0 -lossmax 50
BLE Shell>
```

4. Set the decision instructions using the gap setdecinstr command. The instructions are used when listening for advertisements containing decision PDUs.
5. Start scanning and filter duplicates.
6. Connect to the desired device in the scanned devices list.

```
BLE Shell>gap setdecinstr
BLE Shell>
--> GAP Event: Decision Instructions Setup Complete.
BLE Shell>gap scanstart filter
BLE Shell>
-> GAP Event: Scan started.
BLE Shell>
--> GAP Event: Found device 0 : C4603770BCC5 -23 dBm
 Advertising Extended Data:
gap connect 0
BLE Shell>
-> GAP Event: Scan stopped.
BLE Shell>
--> GAP Event: Connected to peer 0
BLE Shell>
```

Parent topic: Bluetooth LE Shell

Periodic Advertising with Responses (PAwR) feature

The Bluetooth LE Shell application also supports the Periodic Advertising with Responses feature, which can be enabled by performing the following steps:

- In app_preinclude.h file, set BLE_SHELL_PAWR_SUPPORT to 1.

This feature requires two (or more) devices:

- GAP Broadcaster: transmits advertising PDUs at a fixed interval. (AUX_SYNC_SUBEVENT_IND)
- GAP Observer (one or more): scans for advertising PDUs and synchronizes with the advertising train. Sends responses PDUs in the synced subevents. (AUX_SYNC_SUBEVENT_RSP)

To showcase the functionality, two platforms are used in the following setup.

Steps to perform on the GAP Broadcaster device:

1. Configure the periodic advertising parameters. In the below example, a set of implicit values are used. There are 2 subevents per interval, each interval repeating at 1 second. There are 4 response slots configured per subevent, with the first response slot starting at 125ms from the advertising packet.

```
BLE Shell>gap periodiccfg

-->  Periodic Advertising Parameters:
    -->  Periodic Advertising Handle: 1
    -->  Periodic Advertising Interval: 2000 ms
    -->  Number of subevents: 2
    -->  Interval between subevents: 156.25 ms
    -->  Time between the advertising packet in a subevent and the first response slot: 125.0 ms
    -->  Time between response slots: 1.250 ms
    -->  Number of response slots: 4
BLE Shell>
-->  GAP Event: Periodic Advertising parameters successfully set.
```

   Alternatively, the command does accept all the mentioned parameters to be changed. The below command can be used to configure the exact same values.

```
BLE Shell>gap periodiccfg -numsubevents 2 -subint 125 -rspslotdelay 100 -rspslotspace 10 -numrspslot 4
BLE Shell>
--> GAP Event: Periodic Advertising parameters successfully set.
```

2. Configure the subevent data on the advertiser for each subevent. Each instance of the gap periodicsubeventdata command sets each subevent data for the configured number of subevents. In this used example, the first command sets the data for the first subevent, the second command sets the data for the second subevent. The upper limit is the lowest of the following: SHELL_PER_ADV_MAX_NUM_SUBEVENTS from app_preinclude.h or the number of subevents set using gap periodiccfg.

```
BLE Shell>gap periodicsubeventdata 255 696E666F31
BLE Shell>gap periodicsubeventdata 255 696E666F32
```

When the last subevent data is set, any succeeding command will erase the previously set data for all subevents, and the data in the ongoing command will be set in the first subevent.

Alternatively, the command accepts more advertising data structures for one subevent, up to SHELL_EXT_ADV_DATA_MAX_AD_STRUCTURES.

```
BLE Shell>gap periodicsubeventdata 27 01CAFECAFECAFE 255 696E666F31
```

To manually clear the data set for all the currently set subevents, you may issue the following command:

```
BLE Shell>gap periodicsubeventdata -erase
```

3. Start extended advertising.

```
BLE Shell>gap extadvstart
BLE Shell>
--> GAP Event: Extended Advertising parameters successfully set.

BLE Shell>
--> GAP Event: Extended Advertising data successfully set.

BLE Shell>
--> GAP Event: Advertising state changed successfully!
```

4. Start periodic advertising.

```
BLE Shell>gap periodicstart
BLE Shell>Periodic Advertising state changed successfully!
```

Steps to perform on the GAP Observer device:

1. Start scanning using the gap scanstart command. Optionally you can modify the scan parameters using the gap scancfg command.

```
BLE Shell>gap scanstart
BLE Shell>
-> GAP Event: Scan started.
```

2. Issue a periodic sync command with the target address of the Broadcaster device that is periodic advertising. You can use the gap address command on the Broadcaster to obtain the address.

```
BLE Shell>gap periodicsync -peer 006037A55E86
```

When the sync is established, events will be printed at the console.

```
--> GAP Event: Periodic Advertising Sync Established
--> GAP Event: Periodic Device Scanned
      Event Counter: 8
      Subevent Synced: 0
      RSSI: -38 dBm
      Advertising Data: info1
```

3. Synchronize the Observer device with the subevents needed. For this example, we will synchronize the Observer with both subevents using the following command. Implicitly, the Observer synchronizes to subevent 0.

```
BLE Shell>gap periodicsyncsubevent -peradvproperties 0 -numsubevents 2 -subevents 0x00,0x01
...
BLE Shell>Set Sync Subevent command successfully completed.
```

   After this, GAP Events of type Periodic Device Scanned should be displayed in the console for each of the subevents synchronized.

```
--> GAP Event: Periodic Device Scanned
      Event Counter: 169
      Subevent Synced: 0
      RSSI: -34 dBm
      Advertising Data: info1
--> GAP Event: Periodic Device Scanned
      Event Counter: 169
      Subevent Synced: 1
      RSSI: -38 dBm
      Advertising Data: info2
```

4. The last step to have a complete exchange of data is to set the response(s) on the Observer device. The next 2 commands will set the data for the 2 subevents synced at the previous step.

```
BLE Shell>gap periodicresponsedata -responsesubevent 0 -responseslot 0 -data 255␣
↪64657669636531696E666F31
BLE Shell>gap periodicresponsedata -responsesubevent 1 -responseslot 0 -data 255␣
↪64657669636531696E666F32
```

   The -responsesubevent parameter indicates the subevent the data is set for. The -responseslot parameter indicates the response slot the data is sent at this value should be within the range 0 to the number of response slots set at periodiccfg.

   To scale the demo to use more Observer devices, repeat steps 1-3 for each of the added device. Also use example at step 4, with the adaptation of the -responseslot according to the device index. The demo is designed to have a new device for each of the response slots available. Also, change the data to reflect the response of the extra device.

   Note: *The* -data *parameter must be the last of the* periodicresponsedata *command as it can contain a volatile number of advertising data structures.*

   Alternatively, the command may contain additional advertising data structures.

```
BLE Shell>gap periodicresponsedata -responsesubevent 0 -responseslot 0 -data 27␣
↪01CAFECAFECAFE 255 64657669636531696E666F31
BLE Shell>gap periodicresponsedata -responsesubevent 1 -responseslot 0 -data 27␣
↪01CAFECAFECAFE 255 64657669636531696E666F32
```

   To manually clear the data set for all the currently set subevents, you may issue the following command:

```
BLE Shell>gap periodicresponsedata -erase
```

Initiate a connection from PAwR

PAwR feature allows for connection initiation from the Broadcaster device. To do this, the devices have to be synchronized. The minimum steps required for this are steps 1, 3, 4 on the GAP Broadcaster device and steps 1, 2, GAP Observer device.

After performing the mentioned steps, the Broadcaster device must issue the following command:

```
BLE Shell>gap connectpawr -subevent 0 -peer 00603728063E -peeraddrtype 0
```

Upon successful connection the following message will be displayed.

```
--> GAP Event: Connected to peer 0
```

Parent topic: Bluetooth LE Shell

Monitoring Advertisers (MonAdv) feature

The Bluetooth LE Shell application also supports the Monitoring Advertisers feature, which can be enabled by performing the following steps:

- In app_preinclude.h file, set BLE_SHELL_MONADV_SUPPORT to 1.

This feature requires two (or more) devices:

- GAP Broadcaster (one or more): transmits advertising PDUs.
- GAP Observer: scans for advertising PDUs and shall generate an event if, during the timeout period set by the Application, an advertisement has not been received from that peer with an RSSI value above the RSSI low threshold set by the Application.

To showcase the functionality, two platforms are used in the following setup.

Steps to perform on the GAP Broadcaster device:

1. Get the device address of the target device to be monitored:

```
BLE Shell>gap address

--> GAP Event: Random Static Address:D7E448669EA4
```

Note the device address to be used later, at the scanner device.

2. Configure advertising parameters and start advertising.

For this example we will set advertising at 100 ms interval.

```
BLE Shell>gap advcfg -interval 100
BLE Shell>
--> GAP Event: Advertising parameters successfully set.
```

```
BLE Shell>gap advstart
BLE Shell>
--> GAP Event: Advertising parameters successfully set.

BLE Shell>
--> GAP Event: Advertising data successfully set.

BLE Shell>
--> GAP Event: Advertising state changed successfully!
```

Steps to perform on the GAP Observer device:

1. Using the device address previously obtained, add it to the Monitoring Advertisers list.

```
BLE Shell>gap monadvadd -addr D7E448669EA4 -type 1 -rssilow -65 -rssihigh -55 -timeout 1
BLE Shell>
--> GAP Event: Device added to Monitored Advertisers List.
```

- The -type and -addr parameters are used to identify an advertising device.
- The -rssilow parameter is set to the RSSI value below which a Monitored Advertisers Report event shall be generated when the associated timer expires for that device.
- The -rssihigh parameter is set to the RSSI value equal to or above which a Monitored Advertisers Report event may be triggered for that device.
- The -timeout parameter is set to the timeout time in seconds for the device.

2. Start the scanning using the default, predefined parameters:

```
BLE Shell>gap scanstart
BLE Shell>
-> GAP Event: Scan started.

BLE Shell>
--> GAP Event: Found device 0 : 18C23C3C23C1 -64 dBm
--> GAP Event: Found device 1 : 7A7410BFD06C -55 dBm
--> GAP Event: Found device 2 : 18C23C3C23CD -61 dBm
...
```

3. Enable monitoring advertisers.

```
BLE Shell>gap monadven -enable 1
BLE Shell>
--> GAP Event: GAP Event: Monitoring Advertisers enabled.
```

If the devices are distant to each other, the event message should be printed at the console:

```
BLE Shell>
--> GAP Event: Monitored Advertiser Report
    Address Type: 1
    Address: D7E448669EA4
    Condition: RSSI Low Threshold
```

If the devices are brought close together, the event message should be printed at the console:

```
--> GAP Event: Monitored Advertiser Report
    Address Type: 1
    Address: D7E448669EA4
    Condition: RSSI High Threshold
```

To restart the Monitoring Advertisers reporting

Reuse the same command and same parameters as the enable command.

```
BLE Shell>gap monadven -enable 1
BLE Shell>
--> GAP Event: Monitoring Advertisers restarted.
```

To stop the Monitoring Advertisers reporting

```
BLE Shell>gap monadven -enable 0
BLE Shell>
--> GAP Event: Monitoring Advertisers disabled.
```

To remove a device from the Monitoring Advertisers list:

```
BLE Shell>gap monadvrem -addr D7E448669EA4 -type 1
BLE Shell>
--> GAP Event: Device removed from Monitored Advertisers List.
```

To clear the Monitoring Advertisers list of the added devices:

Run the following command:

```
BLE Shell>gap monadvclear
BLE Shell>
--> GAP Event: Monitored Advertisers List cleared.
```

To get the size of the Monitoring Advertisers:

Run the following command:

```
BLE Shell>gap monadvsize
```

The size should be printed as indicated in this output message:

```
BLE Shell>
--> GAP Event: Monitored Advertisers List size: 8
```

Parent topic: Bluetooth LE Shell

Connection Subrating feature

The Bluetooth LE Shell application also supports the Connection Subrating feature, which can be enabled by performing the following steps:

- In app_preinclude.h file, set BLE_SHELL_CONN_SBR_SUPPORT to 1.

This feature requires two connected devices to be demonstrated. There are three ble_shell commands implemented to handle this feature.

Connection subrating configuration

- gap sbrcfg does not require a connection to be established.
- gap sbrcfg can be issued without any parameters to return the default configuration.

```
  BLE Shell>gap sbrcfg

--> Connection Subrate Parameters:
   --> subrateMin: 4
   --> subrateMax: 4
   --> Connection Latency: 0
   --> continuationNumber: 2
   --> Supervision Timeout: 32000 ms
BLE Shell>
```

- optional parameters can be used to configure connection subrating: gap sbrcfg[-sbrmin minSubrateFactor] [-sbrmax maxSubrateFactor] [-latency latency] [-contnum continuationNumber] [-timeout timeout in ms]

```
 BLE Shell>gap sbrcfg -sbrmin 4 -sbrmax 4 -latency 0 -contnum 2 -timeout 32000

--> Connection Subrate Parameters:
   --> subrateMin: 4
   --> subrateMax: 4
   --> Connection Latency: 0
   --> continuationNumber: 2
   --> Supervision Timeout: 32000 ms
BLE Shell>
```

Set default connection subrating parameters

- gap setdefsbrparam does not require a connection to be established.
- It can be issued only on the central side.
- It sets the parameters exposed/set by the gap sbrcfg command.

```
BLE Shell>gap setdefsbrparam
BLE Shell>
--> GAP Event: Default Connection Subrate Parameters Setup Complete.

BLE Shell>
```

Connection subrate request

- gap connsbrreq peerID requires a connection to be established and the peerId as parameter.
- It can be issued on the central or on the peripheral side.
- When the connection subrating is applied the subrate change event is received.

```
LE Shell>gap connsbrreq 0
BLE Shell>
--> GAP Event: Subrate Changed 0
   --> subrateFactor: 4
   --> peripheralLatency: 0
   --> continuationNumber: 2
   --> supervisionTimeout: 32000 ms
BLE Shell>
```

Usage

To showcase the functionality, the throughput feature can be used.

1. Configure the desired subrating configurations parameters on both central and peripheral.

```
BLE Shell>gap sbrcfg -sbrmin 4 -sbrmax 4 -latency 0 -contnum 2 -timeout 32000

--> Connection Subrate Parameters:
   --> subrateMin: 4
   --> subrateMax: 4
   --> Connection Latency: 0
   --> continuationNumber: 2
   --> Supervision Timeout: 32000 ms
BLE Shell>
```

2. Set the default connection subrating parameters on central.

```
BLE Shell>gap setdefsbrparam
BLE Shell>
--> GAP Event: Default Connection Subrate Parameters Setup Complete.

BLE Shell>
```

3. Start the throughput tx on peripheral.

```
BLE Shell>thrput start tx
BLE Shell>
--> GAP Event: Advertising parameters successfully set.

BLE Shell>
--> GAP Event: Advertising data successfully set.

BLE Shell>
--> GAP Event: Advertising started.>
```

4. Start the throughput rx on central.

```
BLE Shell>thrput start rx
BLE Shell>
-> GAP Event: Scan started.

Found device:
THR_PER
006037327E67
-> GAP Event: Scan stopped.

--> GAP Event: Connected to peer 0
BLE Shell>Throughput test started.
Receiving packets...

************************************
***** TEST REPORT FOR PEER ID 0 ****
************************************

Packets received: 1000
Total bytes: 244000
Receive duration: 2613 ms
Average bitrate: 747 kbps

************************************
********** END OF REPORT ***********
************************************
```

5. Request connection subrating from the peripheral. The subrate change event should be observed on both boards.

```
BLE Shell>gap connsbrreq 0
BLE Shell>
--> GAP Event: Subrate Changed 0
   --> subrateFactor: 4
   --> peripheralLatency: 0
   --> continuationNumber: 2
   --> supervisionTimeout: 32000 ms
BLE Shell>
```

6. Start the throughput rx on central again .

```
thrput start 0 rx
Throughput test started.
Receiving packets...
BLE Shell>
```

7. Start the throughput tx on peripheral again .

```
thrput start 0 tx
Throughput test started.
Sending packets...
```

8. When the test is finished the test report should be printed on the central side.

```
************************************
***** TEST REPORT FOR PEER ID 0 ****
************************************

Packets received: 1000
Total bytes: 244000
Receive duration: 2645 ms
Average bitrate: 737 kbps
```

(continues on next page)

(continued from previous page)

```
**********************************
********** END OF REPORT ***********
**********************************
```

As can be observed the throughput with the subrating applied is almost similar with the throughput without subrating while the energy efficiency when no data is being transmitted is improved given the effective connection interval is subrate factor bigger.

Parent topic: Bluetooth LE Shell

LE Power Control feature

The Bluetooth LE Shell application supports the LE Power Control feature, which allows monitoring and control of transmit power levels and path loss reporting on active connections. This feature is available on platforms supporting Bluetooth Core Specification 5.2 or later.

- In app_preinclude.h file, ensure the following defines are set:
  - gBLE52_d set to 1 (BLE 5.2 support)
  - gBLE52_LePowerControlSupport_d set to TRUE
  - gHostInitEnableExpmFeatures_c set to 1

Overview

LE Power Control provides the following capabilities:

- Read local and remote transmit power levels for different PHY types
- Monitor path loss between devices with configurable thresholds
- Receive notifications when power levels or path loss changes
- Configure path loss reporting parameters

This feature requires an active connection between two BLE devices.

Shell Commands

Enhanced Read Transmit Power Level

Reads the current and maximum transmit power levels of the local Controller on the ACL connection identified by the Connection_Handle parameter and the PHY indicated by the PHY parameter.

Command: gap pwrread <peerID> <phy>

Parameters:

- peerID: The peer device ID (0-based index)
- phy: PHY type:
  - 1 = LE 1M PHY (gPowerControlLePhy1M_c)
  - 2 = LE 2M PHY (gPowerControlLePhy2M_c)
  - 3 = LE Coded PHY with S=8 data coding (gPowerControlLePhyCodedS8_c)
  - 4 = LE Coded PHY with S=2 data coding (gPowerControlLePhyCodedS2_c)

Example:

```
BLE Shell>gap pwrread 0 1
BLE Shell>
--> GAP Event: Enhanced Read Transmit Power Level
    PHY: LE 1M PHY
    Current TX Power: 0 dBm
    Max TX Power: 10 dBm
BLE Shell>
```

Read Remote Transmit Power Level

Reads the transmit power level used by the remote Controller on a specified PHY on an ACL connection.

Command: gap pwrremote <deviceId> <phy>

Parameters:

- deviceId: The peer device ID (0-based index)
- phy: PHY type (same values as above)

Example:

```
BLE Shell>gap pwrremote 0 1
BLE Shell>
--> GAP Event: Transmit Power Reporting
    Reason: Read Remote TX Power completed
    PHY: LE 1M PHY
    TX Power Level: -11 dBm
    Delta: 0 dB
    Flags: [Normal Range]
BLE Shell>gap pwrremote 0 1
BLE Shell>
--> GAP Event: Transmit Power Reporting
    Reason: Read Remote TX Power completed
    PHY: LE 1M PHY
    TX Power Level: 10 dBm
    Delta: 0 dB
    Flags: [At Maximum]
```

Set Path Loss Reporting Parameters

Configures the thresholds and parameters for path loss monitoring.

Command: gap pathlossparams <deviceId> <highThreshold> <highHysteresis> <lowThreshold> <lowHysteresis> <minTimeSpent>

Parameters:

- deviceId: The peer device ID (0-based index)
- highThreshold: High path loss threshold in dB
- highHysteresis: Hysteresis value for high threshold in dB
- lowThreshold: Low path loss threshold in dB
- lowHysteresis: Hysteresis value for low threshold in dB
- minTimeSpent: Minimum time to spend in a zone before reporting, in connection events

Example:

```
BLE Shell>gap pathlossparams 0 40 10 20 10 10
BLE Shell>
--> GAP Event: Path Loss Reporting Parameters Setup Complete
```

(continues on next page)

(continued from previous page)

```
    Parameters configured successfully!
BLE Shell>
```

Enable Path Loss Reporting

Enables or disables path loss reporting on an active connection.

Command: gap pathlossenable <deviceId> <enable>

Parameters:

- deviceId: The peer device ID (0-based index)
- enable:
  - 0 = Disable path loss reporting
  - 1 = Enable path loss reporting

Example:

```
BLE Shell>gap pathlossenable 0 1
BLE Shell>
-->  GAP Event: Path Loss Reporting State Changed
    Path loss reporting is now enabled!
BLE Shell>
```

Once enabled, path loss threshold events will be reported:

```
BLE Shell>
-->  GAP Event: Path Loss Threshold HIGH zone entered
    Current Path Loss: 48 dB
BLE Shell>
```

Enable Transmit Power Reporting

Enables or disables transmit power change reporting.

Command: gap pwrenable <deviceId> <localEnable> <remoteEnable>

Parameters:

- deviceId: The peer device ID (0-based index)
- localEnable:
  - 0 = Disable local TX power reporting
  - 1 = Enable local TX power reporting
- remoteEnable:
  - 0 = Disable remote TX power reporting
  - 1 = Enable remote TX power reporting

Example:

```
BLE Shell>gap pwrenable 0 1 1
BLE Shell>
-->  GAP Event: Transmit Power Reporting State Changed
    Transmit power reporting enabled!
BLE Shell>
```

When enabled, power change events will be reported:

```
BLE Shell>
--> GAP Event: Transmit Power Reporting
    Reason: Remote TX power changed
    PHY: LE 1M PHY
    TX Power Level: -5 dBm
    Delta: +3 dB
```

Events

Enhanced Read Transmit Power Level

Returned in response to the `gap pwrread` command.

Event fields:

- PHY: The PHY type (1M, 2M, Coded S=8, Coded S=2)
- Current TX Power: Current transmit power level in dBm (-127 to 20, or "Unavailable")
- Max TX Power: Maximum transmit power level in dBm (-127 to 20)

Path Loss Reporting Parameters Setup Complete

Confirms that path loss reporting parameters have been configured successfully.

Path Loss Reporting State Changed

Confirms that path loss reporting has been enabled or disabled.

Path Loss Threshold

Generated when path loss crosses a configured threshold and stays in the new zone for the minimum time.

Event fields:

- Current Path Loss: The measured path loss in dB
- Zone Entered:
  - `LOW`: Path loss is below low threshold (good signal)
  - `MID`: Path loss is between thresholds (moderate signal)
  - `HIGH`: Path loss is above high threshold (weak signal)

Transmit Power Reporting State Changed

Confirms that transmit power reporting has been enabled or disabled.

Transmit Power Reporting

Generated when local or remote transmit power changes, or in response to a remote power level read request.

Event fields:

- Reason:
  - `Local TX power changed`: Local controller changed TX power
  - `Remote TX power changed`: Remote device changed TX power
  - `Read Remote TX Power completed`: Response to `gap pwrremote` command
- PHY: The PHY type
- TX Power Level: Power level in dBm (-127 to 20)
- Delta: Change in power level in dB since last report (with +/- sign)
- Flags (for remote read only):

- [At Minimum]: Displayed when at minimum power level
- [At Maximum]: Displayed when at maximum power level
- [Normal Range]: Displayed when between min and max

Usage Example

The following example demonstrates path loss monitoring between two devices: First we create the connection between the devices. **On Device 1 (Peripheral):**

1. Start advertising:

```
BLE Shell>gap devicename HRS
-->  GATTDB Event: Attribute Written
HRS>gap advdata 1 6
HRS>gap advdata 8 HRS
HRS>gap advstart
HRS>
-->  GAP Event: Advertising parameters successfully set.
HRS>
-->  GAP Event: Advertising data successfully set.
HRS>
-->  GAP Event: Advertising state changed successfully!
HRS>gattdb addservice 0x180D
--> Heart Rate
    - Heart Rate Measurement  Value Handle: 14
      - CCCD Handle: 15
    - Body Sensor Location  Value Handle: 17
    - Heart Rate Control Point  Value Handle: 19
-->  GATTDB Event: Service Added in database.
```

On Device 2 (Central):

2. Scan and connect:

```
BLE Shell>gap devicename Collector
-->  GATTDB Event: Attribute Written
Collector>gap scanstart filter
Collector>
-->  GAP Event: Scan started.
Collector>
-->  GAP Event: Found device 0 : F697CFBF6A17 -93 dBm
-->  GAP Event: Found device 1 : HRS 006037CFEAE9 -29 dBm
Collector>gap connect 1
Collector>
-->  GAP Event: Scan stopped.
Collector>
-->  GAP Event: Connected to peer 0
```

3. Configure path loss parameters:

```
Collector>gap pathlossparams 0 40 10 20 10 10
Collector>
-->  GAP Event: Path Loss Reporting Parameters Setup Complete
    Parameters configured successfully!
```

4. Enable path loss reporting:

```
Collector>gap pathlossenable 0 1
Collector>
-->  GAP Event: Path Loss Reporting State Changed
    Path loss reporting is now enabled!
```

5. Monitor path loss (move devices to change signal strength, you will get a new notification when the path loss crosses a threshold and stays in the new zone for the minimum time):

```
Collector>
--> GAP Event: Path Loss Threshold MID zone entered
    Current Path Loss: 30 dB
Collector>
--> GAP Event: Path Loss Threshold LOW zone entered
    Current Path Loss: 18 dB
Collector>
--> GAP Event: Path Loss Threshold HIGH zone entered
    Current Path Loss: 42 dB
```

6. Read current transmit power:

```
Collector>gap pwrread 0 1
Collector>
--> GAP Event: Enhanced Read Transmit Power Level
    PHY: LE 1M PHY
    Current TX Power: -20 dBm
    Max TX Power: 10 dBm
```

7. Enable transmit power reporting:

```
Collector>gap pwrenable 0 1 1
Collector>
--> GAP Event: Transmit Power Reporting State Changed
    Transmit power reporting enabled!
```

8. Monitor transmit power changes (move devices or wait for controller to adjust power):

```
Collector>
--> GAP Event: Transmit Power Reporting
    Reason: Remote TX power changed
    PHY: LE 1M PHY
    TX Power Level: 1 dBm
    Delta: -3 dB
Collector>
--> GAP Event: Transmit Power Reporting
    Reason: Remote TX power changed
    PHY: LE 1M PHY
    TX Power Level: -2 dBm
    Delta: -3 dB
Collector>
--> GAP Event: Transmit Power Reporting
    Reason: Local TX power changed
    PHY: LE 1M PHY
    TX Power Level: -20 dBm
    Delta: -3 dB
```

Notes

- LE Power Control requires Bluetooth 5.2 or later support in both the host stack and the controller firmware
- The path loss zones (LOW/MIDDLE/HIGH) help applications make link adaptation decisions

Hybrid (Dual-mode) Bluetooth Low Energy and Generic FSK

The Hybrid (Dual-mode) Bluetooth Low Energy and Generic FSK application demonstrates Generic FSK transmission/reception and Bluetooth advertising/scanning/multiple connections coexistence.

The Bluetooth LE part of this demo implements a modified version of the Wireless UART demo application, capable of multiple Bluetooth LE connections.

Based on the Hardware link-layer implementation, the Bluetooth Low Energy has a higher priority than the Generic FSK protocol and as the effect, the Generic FSK communication is executed during the Idle states (inactive periods) of the Bluetooth LE. The coexistence of the two protocols is handled internally at the Controller level.

The Bluetooth LE part of the application behaves at first as a GAP central node. It enters GAP Limited Discovery Procedure and searches for other Wireless UART devices to connect. To change the device role to GAP peripheral, use the **ROLESW** button. The device enters GAP General Discoverable Mode and waits for a GAP central node to connect.

The Generic FSK part of the application can either enter in the receive state by double clicking the **SCANSW** button or it can start the periodic transmit by long pressing the **ROLESW** button. It cannot enter in both states at the same time.

The Generic FSK has lower priority than the Bluetooth LE. Therefore, any ongoing Generic FSK receive is paused by the Controller when Bluetooth LE activity is ongoing. The reception is automatically resumed by the Controller when there is no Bluetooth LE activity.

When using Generic FSK, packet loss should be expected. The Generic FSK communication does not offer an acknowledgement mechanism to guarantee success for packet transmission, therefore this communication method does not offer reliability. If the user wants to improve reliability, packet repetition may be used, or the user may implement a custom protocol at application level.

The first Generic FSK transmit command is buffered if there is continuous Bluetooth LE activity (for example, for continuous Bluetooth LE scanning). Any succeeding Generic FSK transmit command indicates failure in the command line interface, if the initial buffered transmit command was not sent yet.

This section describes the implemented profiles and services, user interactions, and testing methods for the Hybrid (Dual-Mode) Bluetooth Low Energy and Generic FSK application.

Implemented profile and services

The Hybrid (Dual-Mode) Bluetooth Low Energy and Generic FSK application implements the GATT client and server for the custom Wireless UART profile and services. It also acts as a Generic FSK transmitter/receiver, repeating a custom packet, at a fixed periodic interval. It uses a predefined identifier, isolated to the address used in the Bluetooth LE protocol of the demo.

- Wireless UART Service (UUID: 01ff0100-ba5e-f4ee-5ca1-eb1e5e4b1ce0)
- Battery Service v1.0
- Device Information Service v1.1

The Wireless UART service is a custom service that implements a custom writable ASCII Char characteristic (UUID: 01ff0101-ba5e-f4ee-5ca1-eb1e5e4b1ce0) that holds the character written by the peer device.

The application is ready to start either Bluetooth LE scanning for Wireless UART Service, Bluetooth LE advertising Wireless UART Service, Generic FSK periodic transmit of a custom packet or Generic FSK receive, in the available slots not used by the Bluetooth LE protocol.

Parent topic: Hybrid (Dual-mode) Bluetooth Low Energy and Generic FSK

Supported platforms

The following platforms support the Hybrid (dual-mode) Bluetooth Low Energy and Generic FSK application:

- KW45B41Z-EVK
- KW45B41Z-LOC
- KW47-EVK
- KW47-LOC
- KW43-LOC
- FRDM-KW43

Parent topic: Hybrid (Dual-mode) Bluetooth Low Energy and Generic FSK

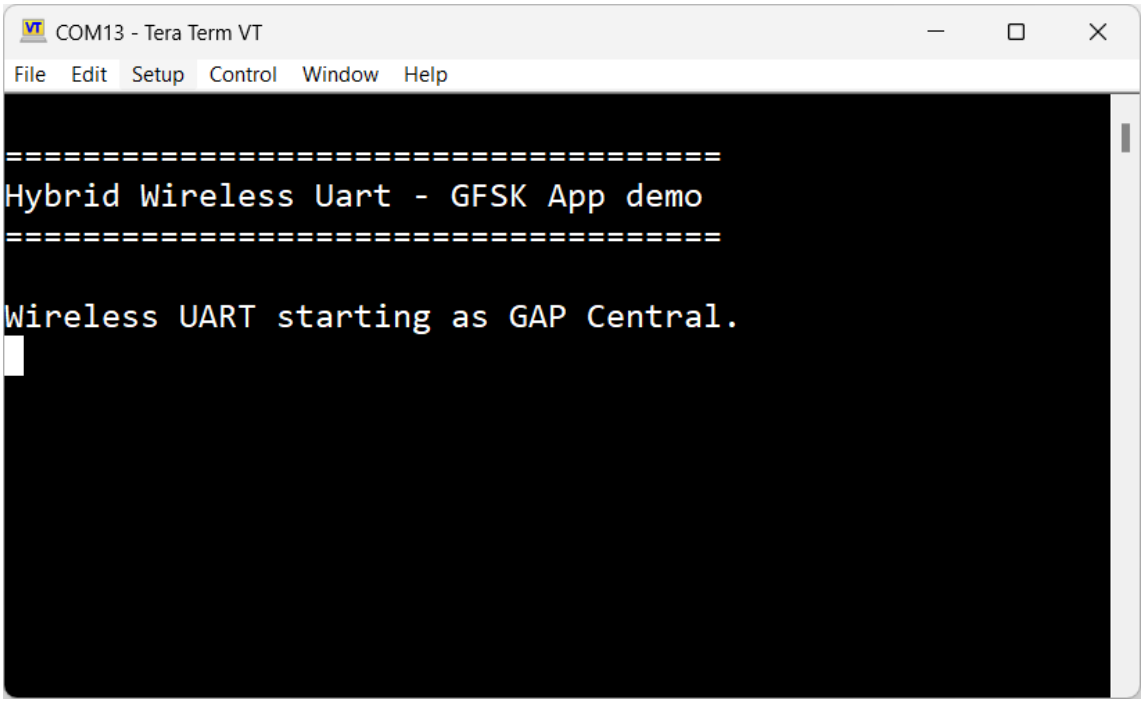
User interface

After flashing the board, the device is in idle mode (all LEDs flashing). To start Bluetooth LE scanning, press the **SCANSW** button. When in GAP Limited Discovery Procedure of GAP General Discoverable Mode, **CONNLED** is flashing. When the node connects to a peer device, **CONNLED** turns solid. To disconnect the node, hold the **SCANSW** button pressed for 2-3 seconds. The node then re-enters GAP Limited Discovery Procedure.

To start Generic FSK receiving, double click the **SCANSW** button and the device starts receiving packets on the same channel as the Bluetooth LE channel 37, with the network address defined in `gGenFSK_NetworkAddress_c`. The receiver only prints the packets that have the predefined identifier at `gGenFSK_Identifier_c`. To stop Generic FSK reception, double click the **ROLESW** button.

On a different device, start Generic FSK transmit by long pressing the **ROLESW** button. To stop the periodic Generic FSK transmit, long press again the **ROLESW** button, if the transmit procedure is ongoing. The long press **ROLESW** acts as a toggle for the transmit.

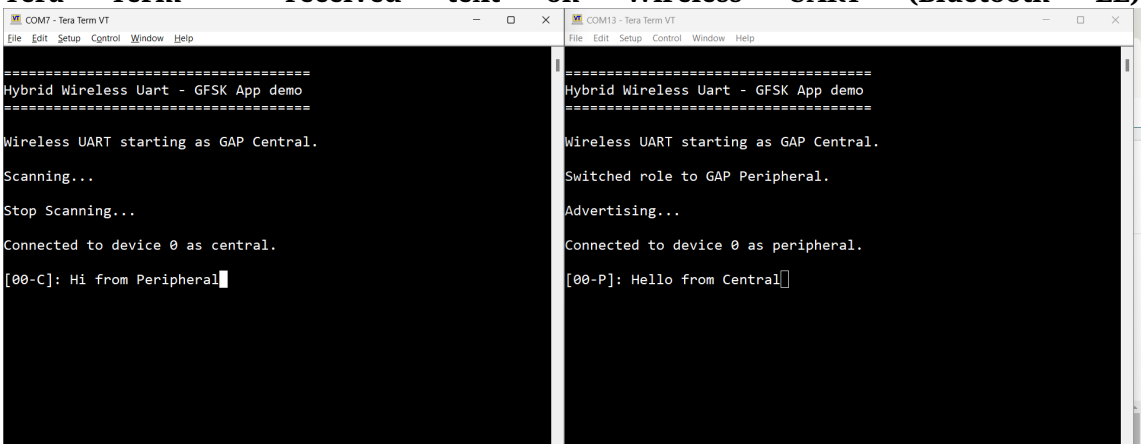
Parent topic: Hybrid (Dual-mode) Bluetooth Low Energy and Generic FSK



Usage

The application is built to work with another supported platform running the same example. When testing with two boards, perform the following steps:

Case 1 (Bluetooth LE)

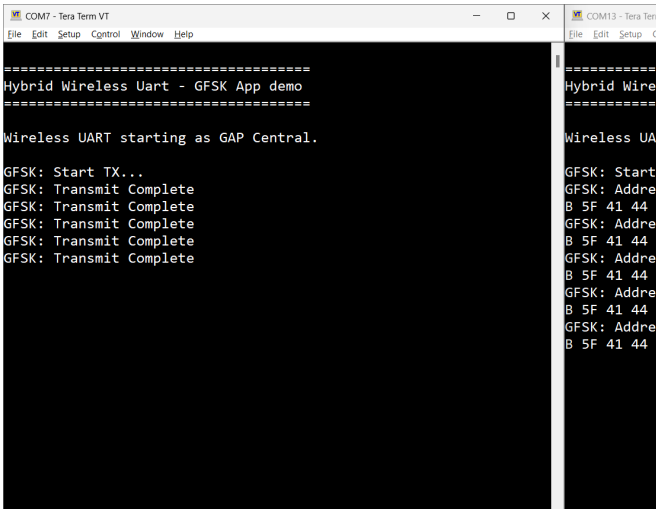


1. Open a serial port terminal and connect to the two boards, in the same manner described in Testing devices. The figure below displays the start screen after the board is reset.

   Tera Term – Hybrid Wireless UART (Bluetooth LE) - Generic FSK start screen

2. The application starts as a GAP central. To switch the role to a GAP peripheral, press the **ROLESW** button. Depending on the role, when pressing the **SCANSW** button, the application starts either scanning or advertising.
3. As soon as the **CONNLED** turns solid on both devices, the user can start writing in one of the consoles. The text appears on the other terminal.
4. After creating a connection, the role (central or peripheral) is displayed on the console. The role switch can be pressed again before creating a new connection. An output example can be observed in the figure below.

Tera Term – received text on Wireless UART (Bluetooth LE)

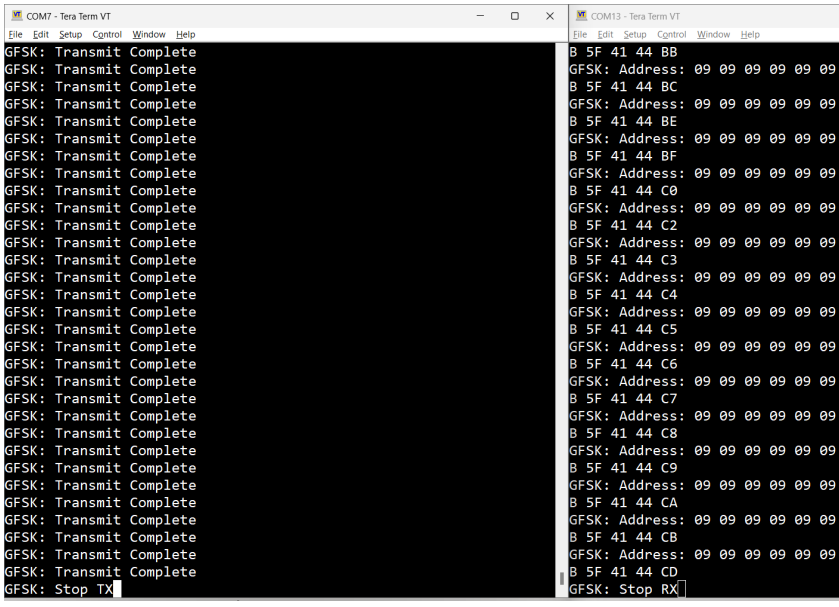


Parent topic: Usage

Case 2 (Generic FSK)

When operating the Generic FSK mode, the following steps should be followed.

1. Open a serial port terminal and connect to the two boards, in the same manner described in Testing devices. The start screen after the board is reset is the same as in Figure.
2. The Generic FSK communication direction is not preset. To start receiving, double click the **SCANSW** button on one board. Then, the device starts receiving packets on the same channel as the Bluetooth LE channel 37.



3. To start transmitting, long press the **ROLESW** button on the other board. The transmitting device uses an identifier known by the receiver and its packets are displayed in the CLI as shown in Figure:

Teraterm – packet transmit/receive on Generic FSK

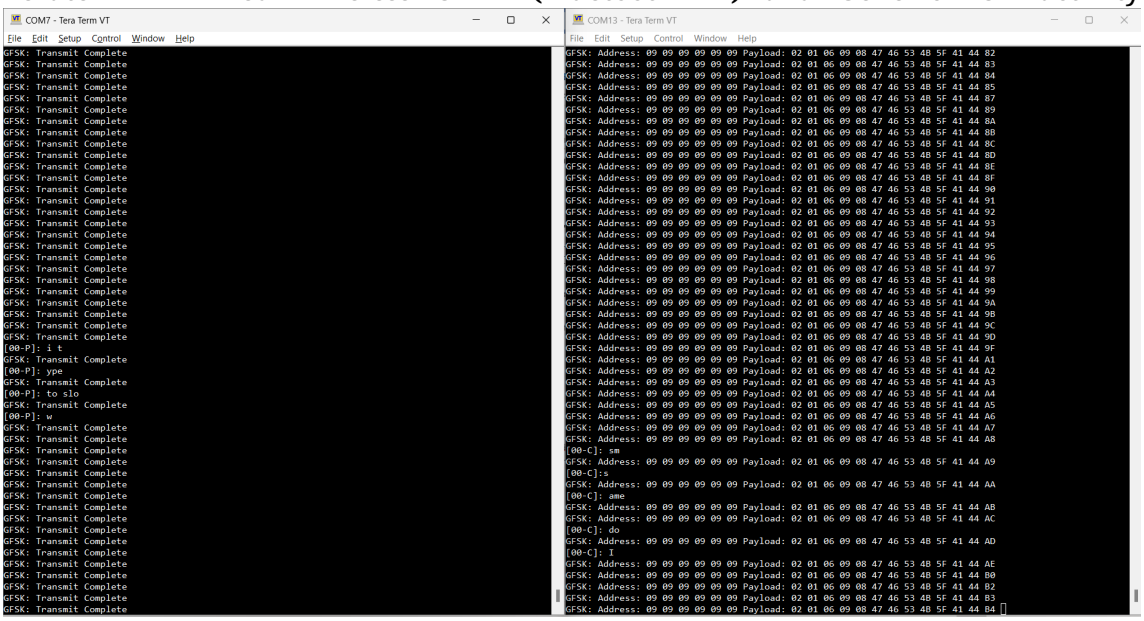
4. To stop Generic FSK reception, double click the **ROLESW** button.
5. To stop the periodic Generic FSK transmit operation, long press the **ROLESW** button again, if the transmit procedure is ongoing. The long press of the **ROLESW** button acts as a toggle for the transmit. At this point, both devices can reverse the direction of communication by following the exact same steps.

   See Figure.

Tera Term – stop Generic FSK activity

Parent topic: Usage

Case 3 (Dual-mode)



The application is ready to combine both scenarios. It can either:

- Establish a Bluetooth LE connection and perform Generic FSK activity.
- During Generic FSK activity, the Bluetooth LE connection can be established and the Controller pauses receiving or announcing the discarded Generic FSK transmissions. This activity is resumed after the Bluetooth LE activity is finished.

To run the Dual-mode scenario, follow the steps below:

1. Establish a Bluetooth LE connection as described in Case 1 (Bluetooth LE).
2. Start Generic FSK activity as described in Case 2 (Generic FSK), independent of the Bluetooth LE roles chosen in Case 1.
3. Start typing in either of the terminals. As seen in Figure, the Bluetooth LE activity is prioritized. In this step, characters are printed in the peer's terminal and Generic FSK continues in the available slots, not used by the Bluetooth LE link.

Teraterm – Mixed Wireless UART (Bluetooth LE) and Generic FSK activity

Parent topic: Usage

Parent topic: Hybrid (Dual-mode) Bluetooth Low Energy and Generic FSK

Customization

Use the steps below to change the default settings of this demo.

For Bluetooth LE, the default advertising config (gAdvParams) parameter is found in the app_config.c file. Also, the scanning parameters (gScanParams) can be found in this file.

The maximum number of connections supported by the Bluetooth LE, for this application, is defined in the app_preinclude.h file, with the macro name gAppMaxConnections_c.

Note: The Generic FSK protocol is active during the inactive periods of the Bluetooth LE protocol. The demo is currently configured to have the scan window equal to the scan interval to make the user aware of this, but this can be changed.

For Generic FSK, the following defines of interest can be found in genfsk_app.h, described below:

Name	Description
gGen-FSK_Netwc	This is the network address used for the Generic FSK, in the transmitter payload. It is implicitly set to the 0x8E89BED6, but this can be reconfigured. Ensure that it is also changed on the receiver in the hybrid_gfsk.c controller file.
gGen-FSK_H0Val	H0 value is used in the header.
gGen-FSK_Identi	This is the identifier used by the transmitter to be filtered at the receiver. The current implementation filters the Generic FSK packets received, based on this define.
gGenF-skApp_TxIı	This is the interval the transmitter will repeat the transmission of a packet. It is set in milliseconds.

Files of interest

The demo can be found in the w_uart_genfsk from the available examples.

The demo is based on the basic Wireless UART with the addition of some Generic FSK files required for working in dual-mode, described below.

File name	Description
genfsk_app.c	Application common module. Handles the HCI commands and events for the Generic FSK. Sends the events to the application.
genfsk_app.h	Application common module. Exposes public functions.
hybrid_gfsk.c	Controller common module. Handles initialization of Generic FSK.
hybrid_gfsk.h	Controller common module. Exposes public functions.

Parent topic:*Bluetooth LE stack and demo applications*

Wireless UART Host

This section describes the implemented profiles and services, user interactions, and testing methods for the Wireless UART Host application.

The Wireless UART Host application is a demonstration of the Extended NBU architectural concept, where the Bluetooth LE Host Stack and the Link Layer both run on the NBU core, while the user-facing application runs on the Application core. The communication between the application and the Host is done via the FSCI protocol running on the inter-core RPMSG transport.

The Wireless UART Host application must be flashed together with the NCP FSCI Blackbox application.

Implemented profile and services

The Wireless UART Host application implements both the GATT client and server for the custom Wireless UART profile and services.

- Wireless UART Service (UUID: 01ff0100-ba5e-f4ee-5ca1-eb1e5e4b1ce0)
- Battery Service v1.0
- Device Information Service v1.1

The Wireless UART service is a custom service that implements a custom writable ASCII Char characteristic (UUID: 01ff0101-ba5e-f4ee-5ca1-eb1e5e4b1ce0) that holds the character written by the peer device.

The application behaves at first as a GAP central node. It enters GAP Limited Discovery Procedure and searches for other Wireless UART devices to connect. To change the device role to GAP peripheral, use the **ROLESW** button. The device enters GAP General Discoverable Mode and waits for a GAP central node to connect.

Parent topic: Wireless UART Host

Supported platforms

The following platforms support the Wireless UART Host application:

- MCX-W72-EVK
- FRDM-MCXW72

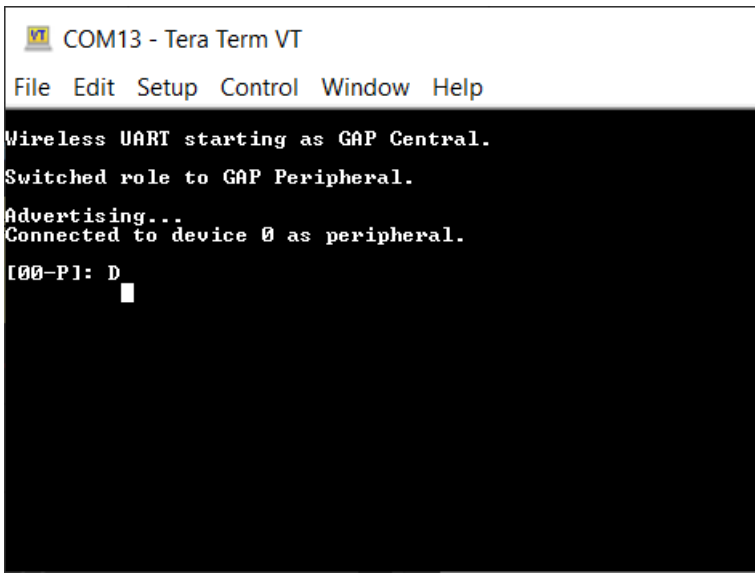
Parent topic: Wireless UART Host

User interface

Ensure that both NCP FSCI Blackbox (for the NBU core) and Wireless UART Host (for the Application core) have been flashed to the board.

After flashing the board, the device is in idle mode (all LEDs flashing). To start scanning, press the **SCANSW** button. When in GAP Limited Discovery Procedure of GAP General Discoverable Mode, **CONNLED** is flashing. When the node connects to a peer device, **CONNLED** turns solid. To disconnect the node, hold the **SCANSW** button pressed for 2-3 seconds. The node then re-enters GAP Limited Discovery Procedure.

Parent topic: Wireless UART Host



Switches and pins

Usage

The application is built to work with another supported platform running either Wireless UART or Wireless UART Host, or with the Wireless UART from the IoT Toolbox application.

When testing with two boards, perform the following steps:

1. Open a serial port terminal and connect to the two boards, in the same manner described in Testing devices. The start screen is blank after the board is reset.
2. The application starts as a GAP central. To switch the role to a GAP peripheral, press the role switch. Depending on the role, when pressing the **SCANSW**, the application starts either scanning or advertising.
3. As soon as the **CONNLED** turns solid on both devices, the user can start writing in one of the consoles. The text appears on the other terminal.
4. After creating a connection, the role (central or peripheral) is displayed on the console. The role switch can be pressed again before creating a new connection. See the figure below.

Tera Term – received text on Wireless UART

When testing with a single board and the IoT Toolbox, perform the following steps:

1. Open a serial port terminal and connect the board in the same manner described in Testing devices. The start screen is blank after the board is reset.

2. Press the role switch button to behave as a GAP peripheral and then press the **SCANSW** button to start advertising. The IoT Toolbox app can then connect. Select UART instead of Console and start typing, as shown in the Figure.

Bluetooth Low Energy CCC Digital Key R3 Application Note Introduction

NXP provides hardware platforms to implement Bluetooth Low Energy applications implementing the Car Connectivity Consortium (CCC) Digital Key R3 functionality. This document provides an overview of the deployment and operation of such applications. This document is also a user guide for the sample applications included in the SDK release package.

Audience

This document is for firmware and system developers who create CCC Digital Key-enabled products. The document also provides a high-level description of CCC Digital Key application scenarios that can be deployed on NXP development boards.

Parent topic:*Introduction*

CCC Digital Key technology overview

The Car Connectivity Consortium (CCC) is a cross-industry organization advancing global technologies for smartphone-to-car connectivity solutions. CCC has developed Digital Key, a new open standard to allow smart devices such as smartphones to act as a vehicle key. Digital Key lets drivers lock and unlock their cars and even allows them to start the engine and share access to friends or valets, using their phones.

The Digital Key Release 3.0 specification enhances Digital Key Release 2.0 by adding passive, location-aware keyless access. Rather than having to pull their mobile devices out to access a car, consumers are able to leave their mobile device in their bag or pocket when accessing and/or starting their vehicle. Passive access is not only vastly more convenient and a better overall user experience, it also allows vehicles to offer new location-aware features.

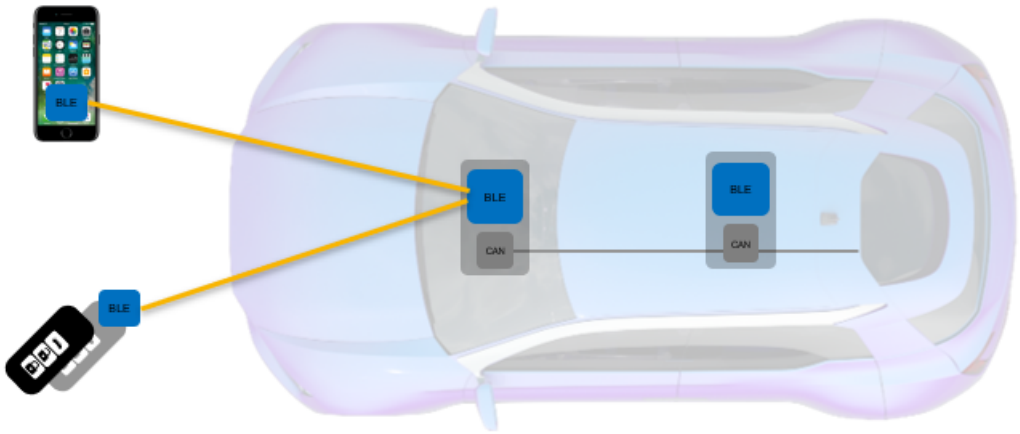
To support these new features, the CCC has developed a specification based on Bluetooth Low Energy in combination with Ultra-Wideband (UWB) to enable passive keyless access and to allow secure and accurate positioning.

CCC Digital Key applications overview

Note: The applications described below implement only the Bluetooth Low Energy functionality described by CCC Digital Key R3. They do not include any UWB or Secure Element functionality. The establishment of secure communications between the demos is simulated using dummy messages.

Digital Key Car Anchor

The Digital Key Car Anchor demo application implements one of the multiple Bluetooth Low Energy anchors that can reside inside the car. The anchor performs a dual role. Inside the CCC Digital Key scope, it is a Bluetooth Low Energy peripheral which, depending on the scenario, can perform both Legacy (1M PHY) and Extended Long Range (500 kbps Coded PHY) advertising, searching for a CCC Digital Key-enabled device such as a smartphone. Simultaneously it can also act as a Bluetooth Low Energy central, scanning for non-CCC key fobs. There can be multiple anchors inside a car. The anchors must act as a single device and share information between them (addresses, bonding data, application specific keys, and such data) such that a smartphone can connect to any one of them depending on positioning and not detect any difference.



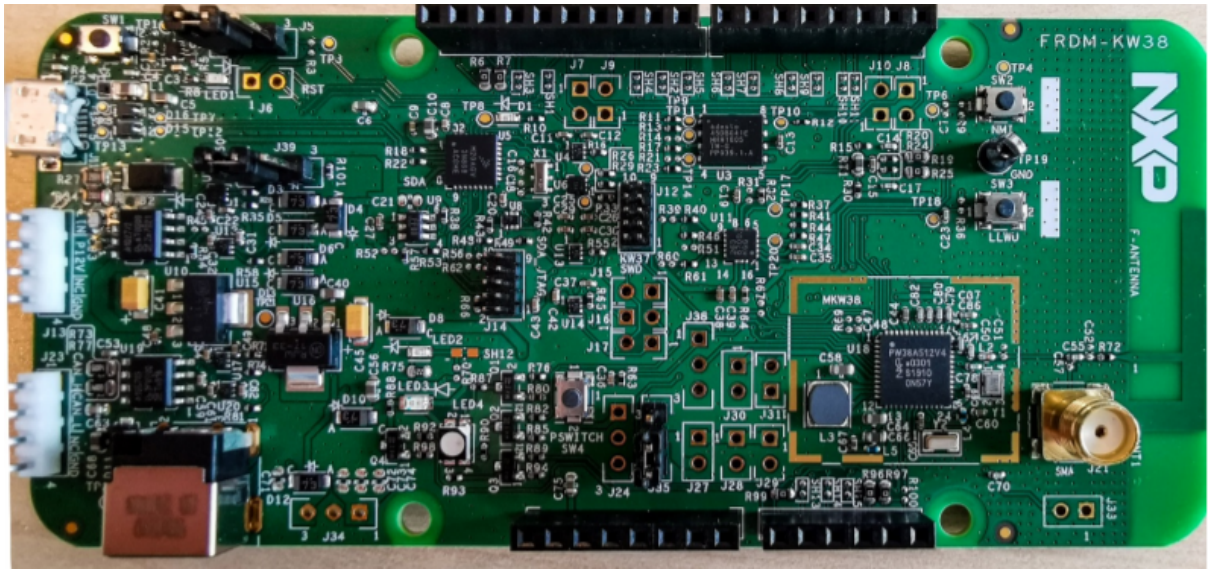
Parent topic:*CCC Digital Key applications overview*

Digital Key Device

The Digital Key Device demo application emulates a CCC Digital Key-enabled smartphone. It acts as a Bluetooth Low Energy central device, scanning for advertising coming from a Digital Key Car Anchor.

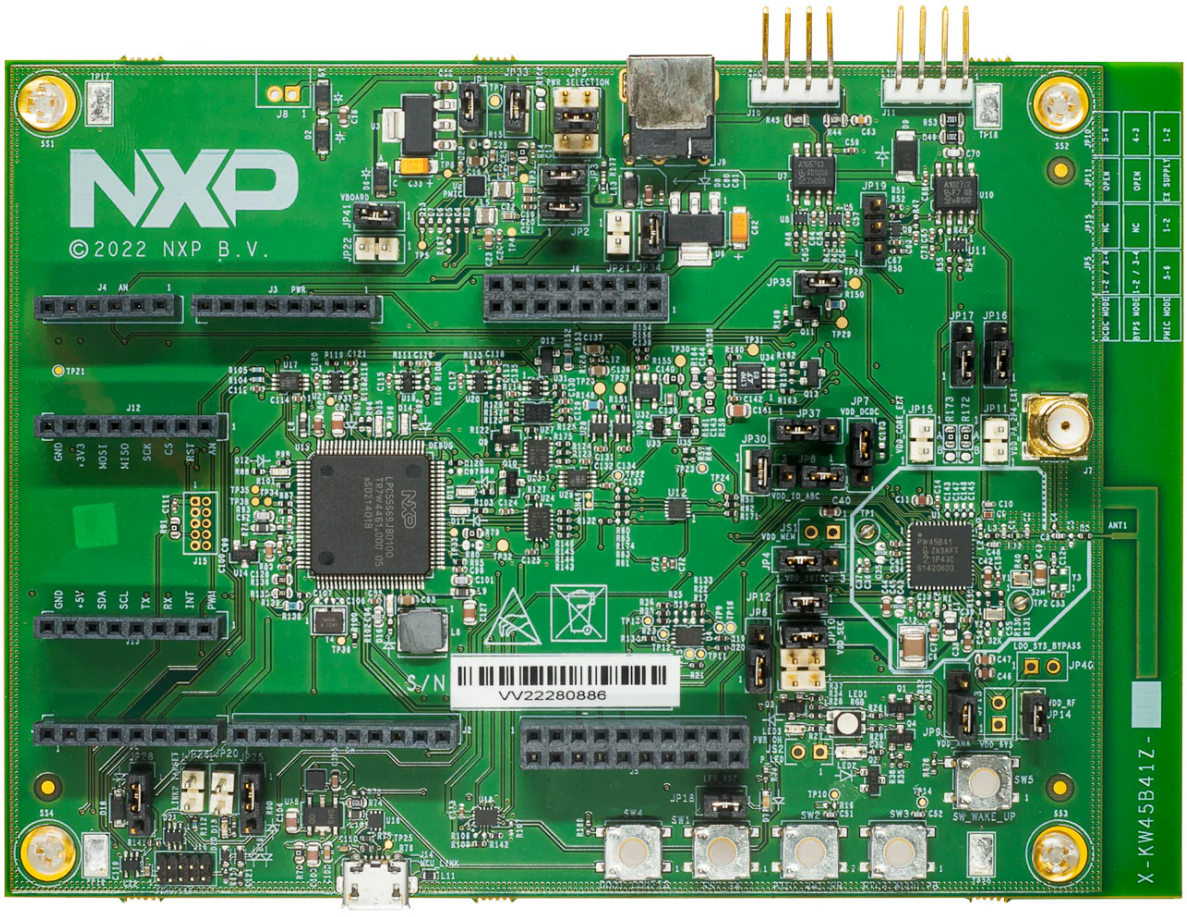
The Figure 1 shows an example deployment of CCC Digital Key R3. Inside the car, there are two Bluetooth Low Energy anchors connected to each other. The Controller Area Network (CAN) bus connects these anchors and is used to exchange security data and other information. Any anchor can perform both advertising and scanning and it is able to connect to a CCC Digital Key R3-enabled smartphone as well as to a non-CCC key fob.

Anchor communicating with a smartphone (CCC) and a key fob (non-CCC)



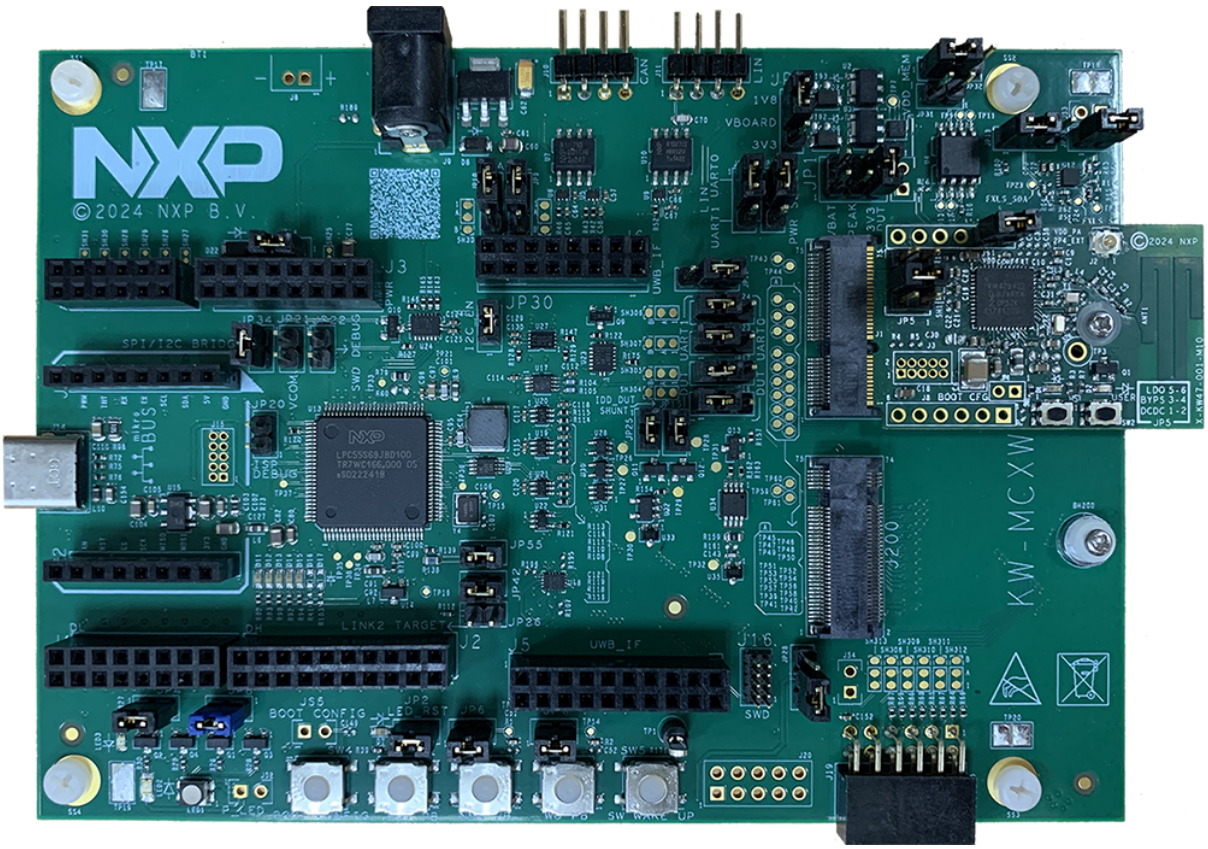
Parent topic:*CCC Digital Key applications overview*

CCC Digital Key hardware platforms

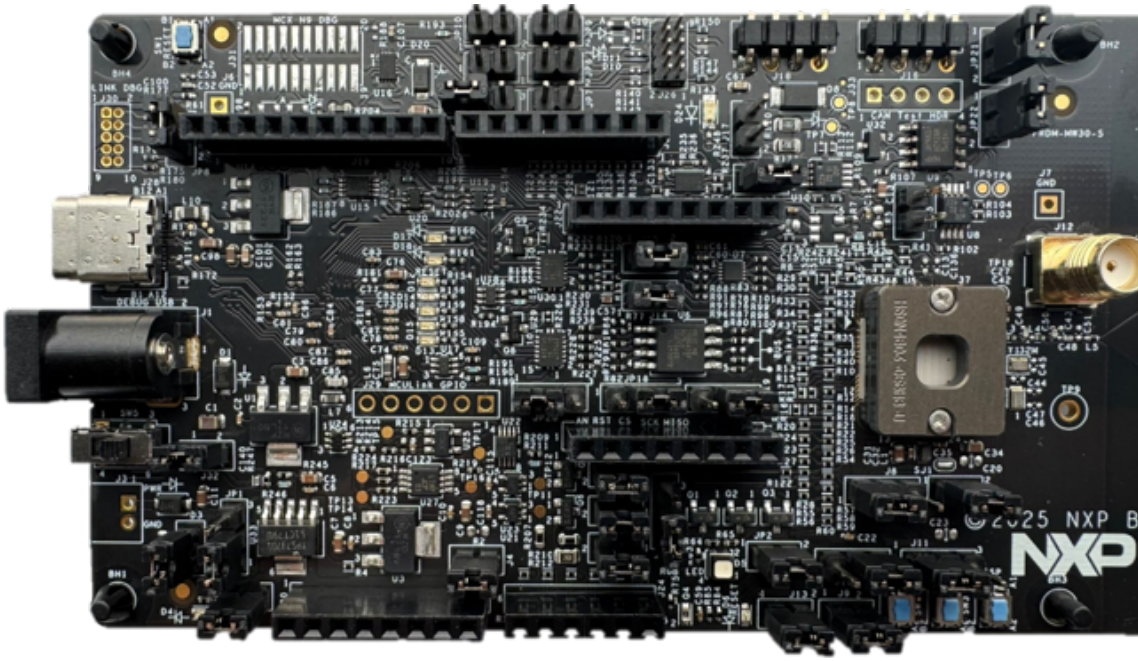


The CCC Digital Key R3 demo applications support the following platforms that have Bluetooth Low Energy transceiver capabilities:

- FRDM-KW38 (see Figure 1)
- KW45B41Z-EVK (see Figure 2)
- KW47-EVK (see Figure 3)
- FRDM-KW43 (see Figure 4)



FRDM-KW38 board



KW45B41Z-EVK board

KW47-EVK board

FRDM-KW43 board

Deploying CCC Digital Key applications software

The software package includes the components necessary for CCC Digital Key R3 application development on the selected NXP platform. These components include:

- Bluetooth Low Energy Host and Controller software libraries (KW38)
- NBU image binaries
- Examples of demo application projects corresponding to CCC Digital Key roles (Device and Car Anchor)

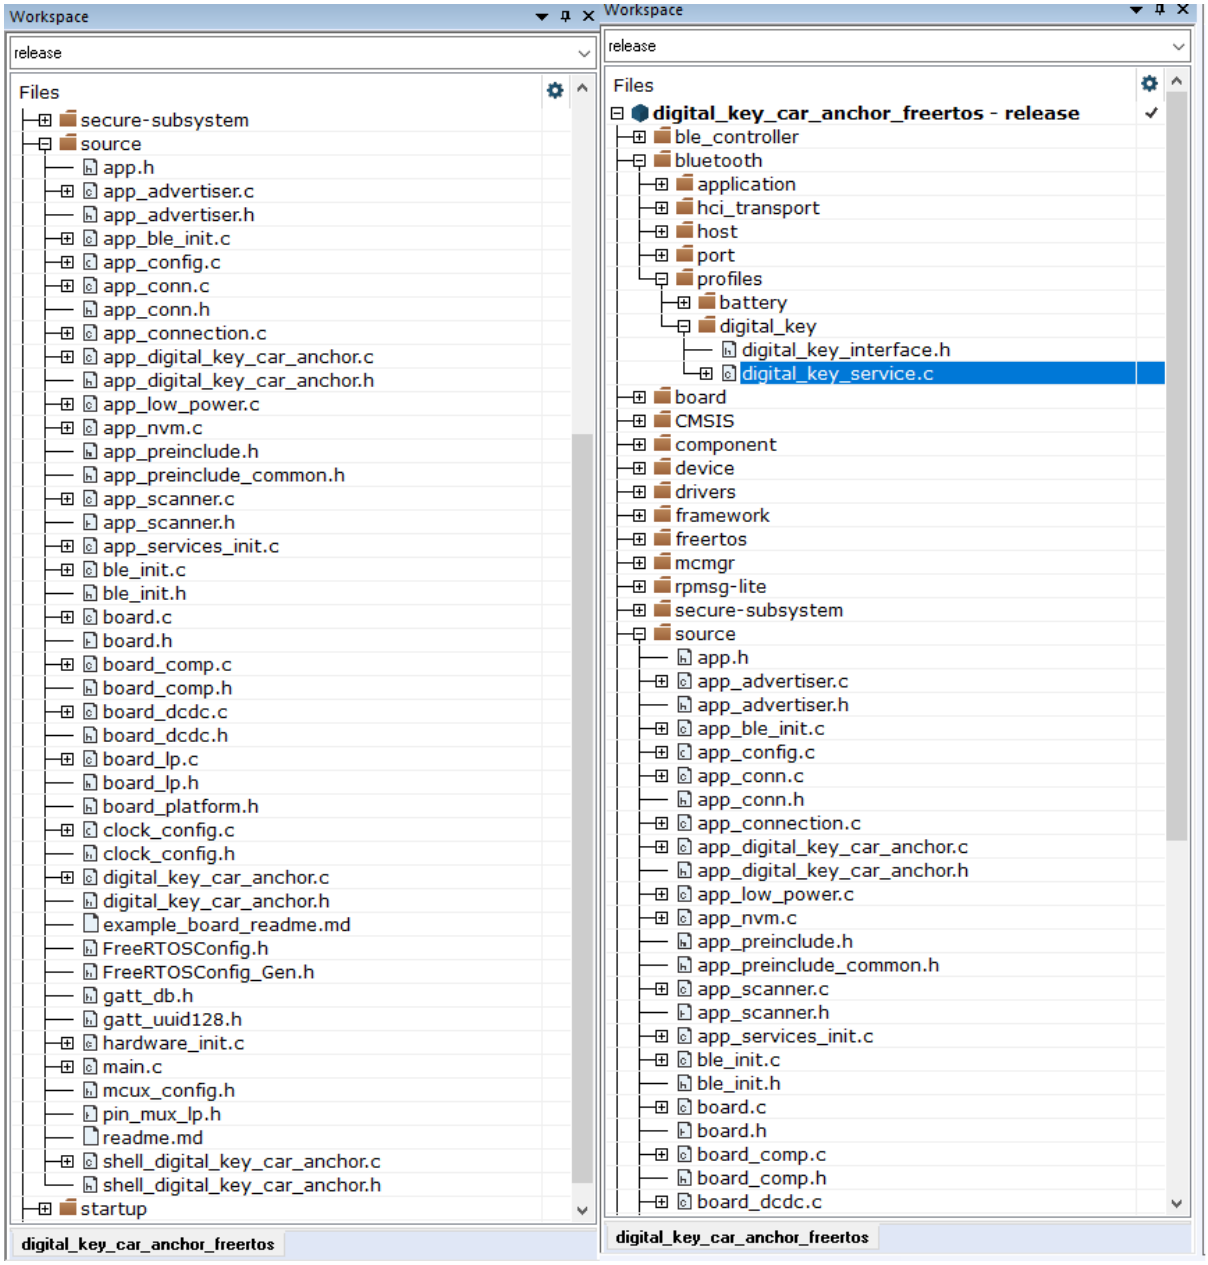
- Platform peripheral drivers, platform startup code, other generic platform software

Note:

Prior to loading any wireless SDK example, update your NBU image with the provided binaries in the following folder of the SDK:

../middleware/wireless/ble_controller/bin.

The demo applications were compiled and tested with **IAR Embedded Workbench** for Arm and **ARMGCC**. It is recommended to use one of these tools.



To open, build, and run any example application, see the *Bluetooth Low Energy Quick Start Guide* document of the corresponding board. The CCC Digital Key R3 examples are built and run in the same fashion as Bluetooth Low Energy examples.

The Figure 1 shows the application folder structure for the *digital_key_car_anchor* project.

The relevant files for CCC Digital Key R3 are the following:

- The main application source files source/digital_key_car_anchor.c and source/app_digital_key_car_anchor.c, and
- The files in bluetooth/profiles/digital_key, which implement the Digital Key Service defined by the CCC Digital Key R3 specification.

Application folder structure in workspace

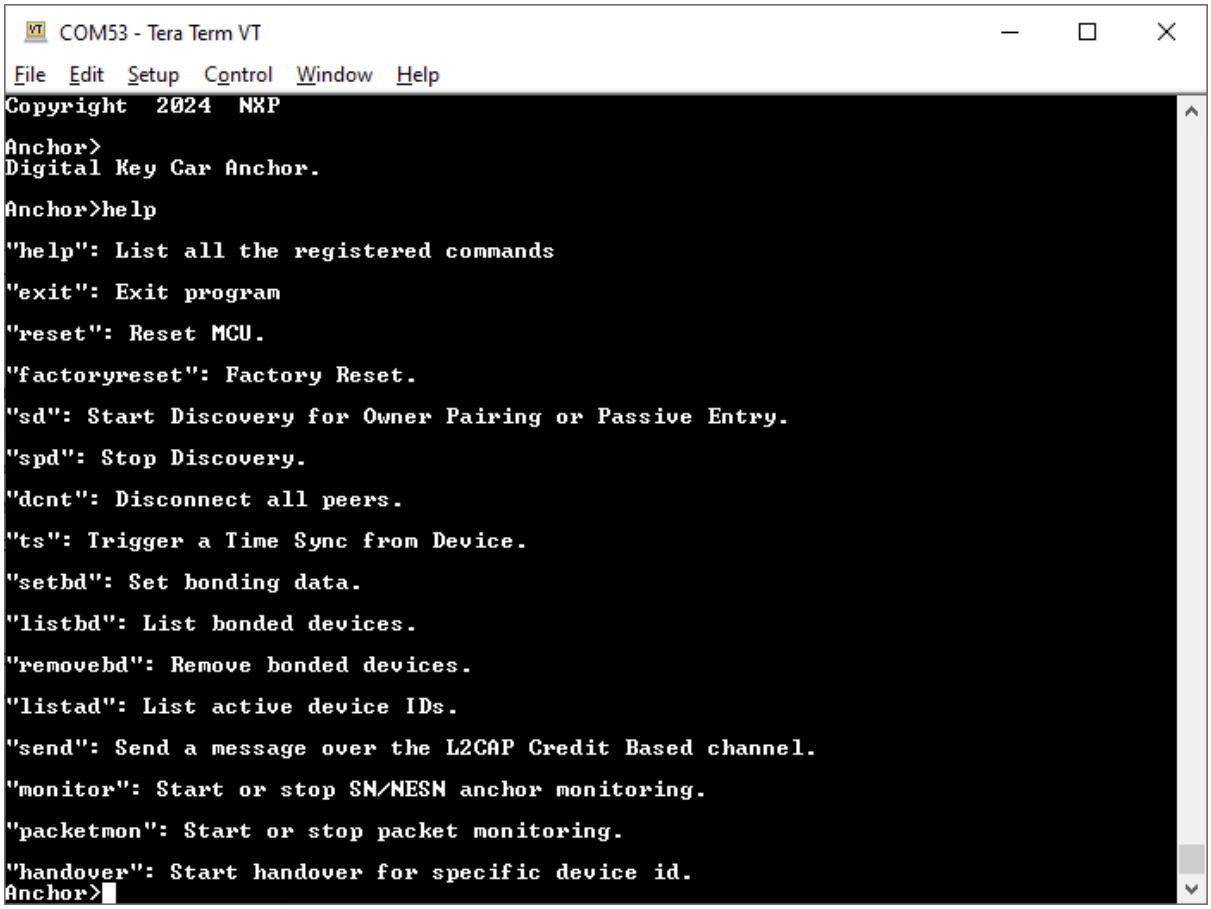
Demo functionality overview

The two demo applications provided showcase the following Digital Key R3 features:

- Owner Pairing between a Device and a Car Anchor
- Passive Entry
- Synchronizing bonding data between Car Anchors
- Connection between a Car Anchor and a non-CCC key fob

The demo applications also showcase the NXP proprietary Connection Handover and Anchor Monitoring features, as well as the A2B feature (secured synchronization of bonding data).

Running CCC Digital Key scenarios using the Shell Interface



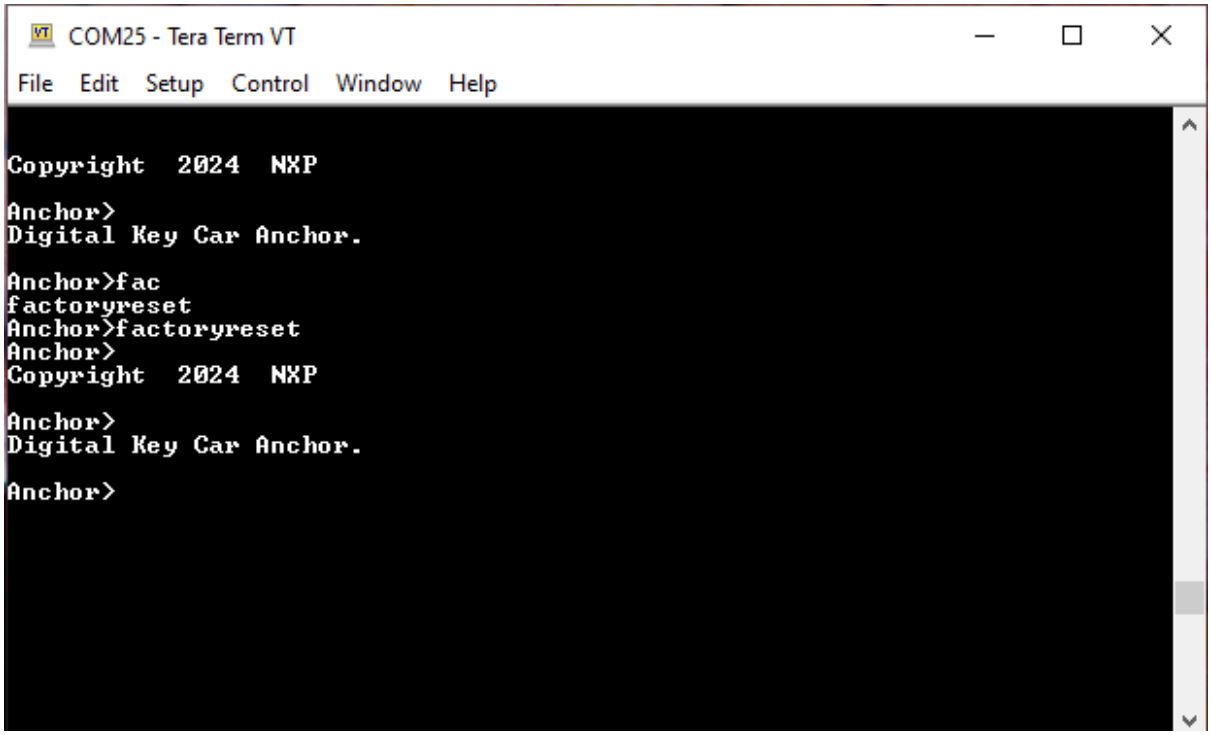
The following CCC Digital Key R3 examples are provisioned by default with a shell command line interface accessible via a Terminal application such as Tera Term:

- Digital Key Car Anchor

- Digital Key Device

After connecting through the Terminal application and pressing the RST switch on the board, a welcome message appears. Entering the command "help" displays the list of available commands and their descriptions. See Figure 1.

List of commands



Owner Pairing Scenario

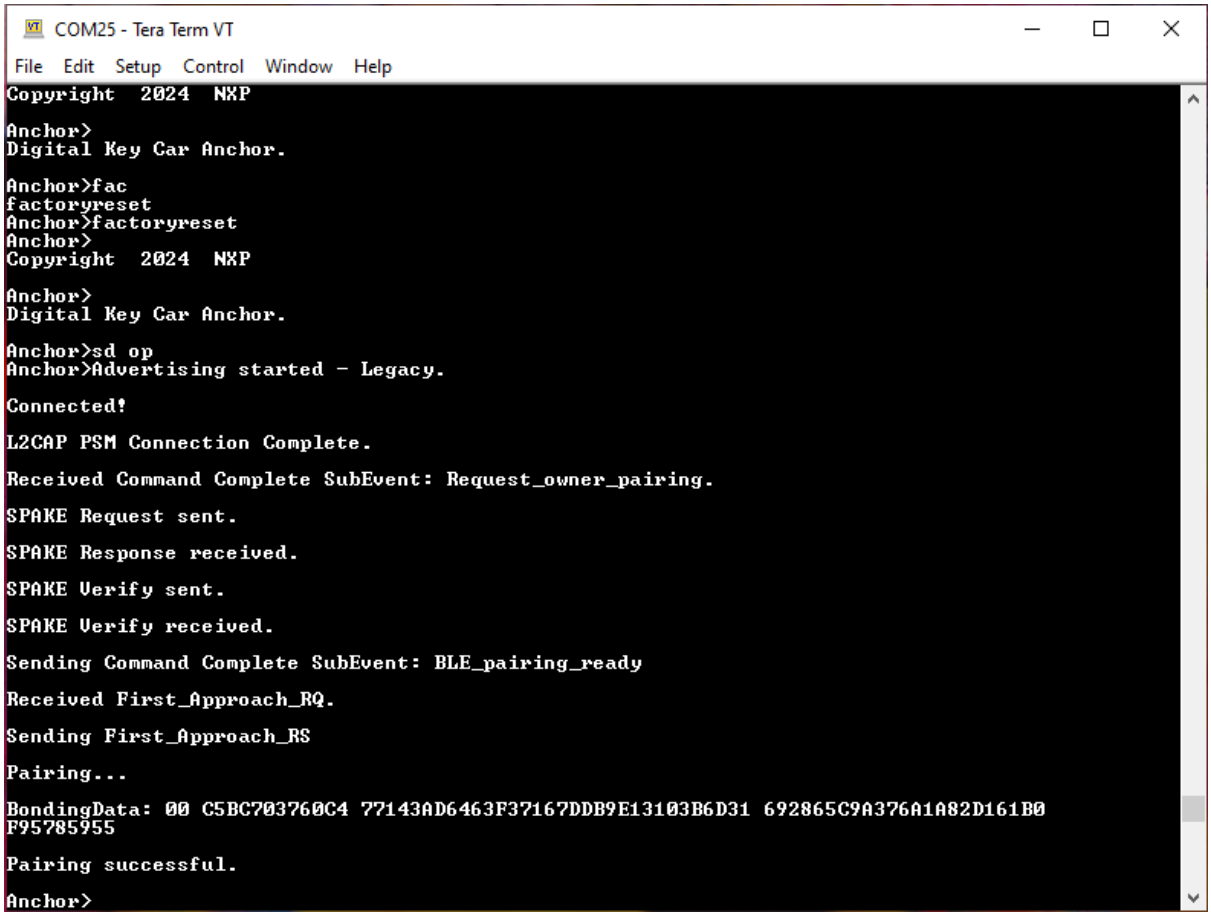
Owner Pairing establishes a bond between the Digital Key Car Anchor and the Digital Key Device as per the CCC Digital Key R3 specification. The Car Anchor starts advertising using Legacy mode on the 1M PHY. The Device scans and connects. After establishing the connection, the Device performs service discovery. This step enables it to discover the DK Service and learn the PSM value it would use in order to open an L2CAP channel to the Car Anchor. This channel is used to exchange data and security information as part of the Bluetooth Low Energy Out-of-Band (OOB) pairing process. All security information exchanged consists of dummy messages. The applications do not currently implement any of the UWB and Secure Element functionality described by CCC Digital Key R3.

The first step is to run the "factoryreset" command on both boards in order to ensure no previous bonding data is present in non-volatile memory. See Figure 1.

Factory reset on Car Anchor

The next step is to run the "sd" command (Start Discovery) on the Device and the "sd op" command on the Car Anchor (Owner Pairing advertising differs from Passive Entry, using a single Legacy advertising set on the 1M PHY). The Car Anchor starts advertising while the Device scans. Since both boards have been factory reset, they follow the Owner Pairing flow. The output of the commands is shown in Figure 2.

Owner Pairing on Car Anchor



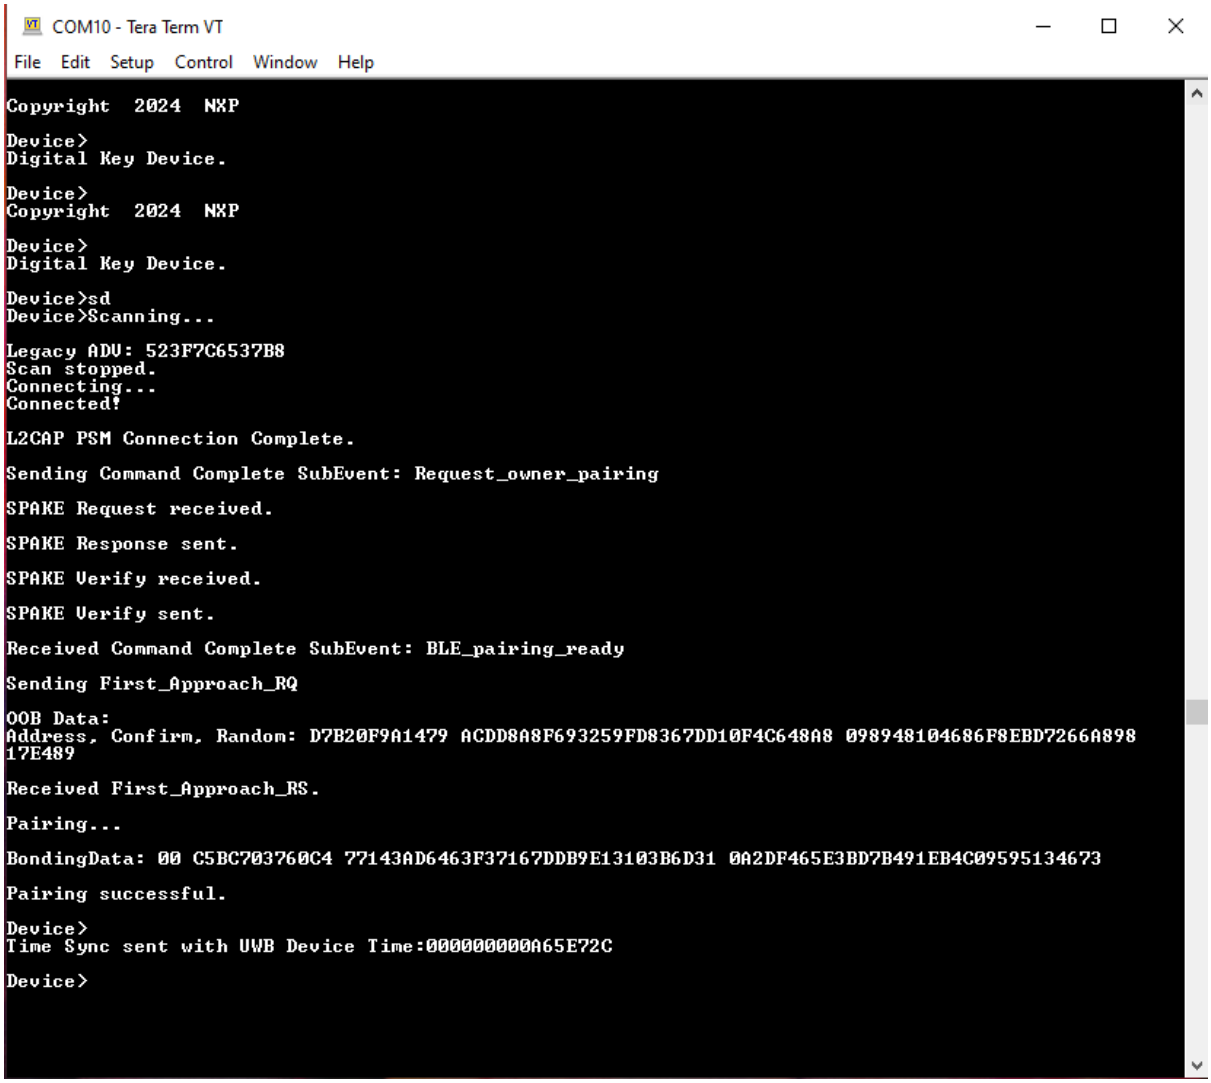


Figure 3 shows the owner pairing on the Device.

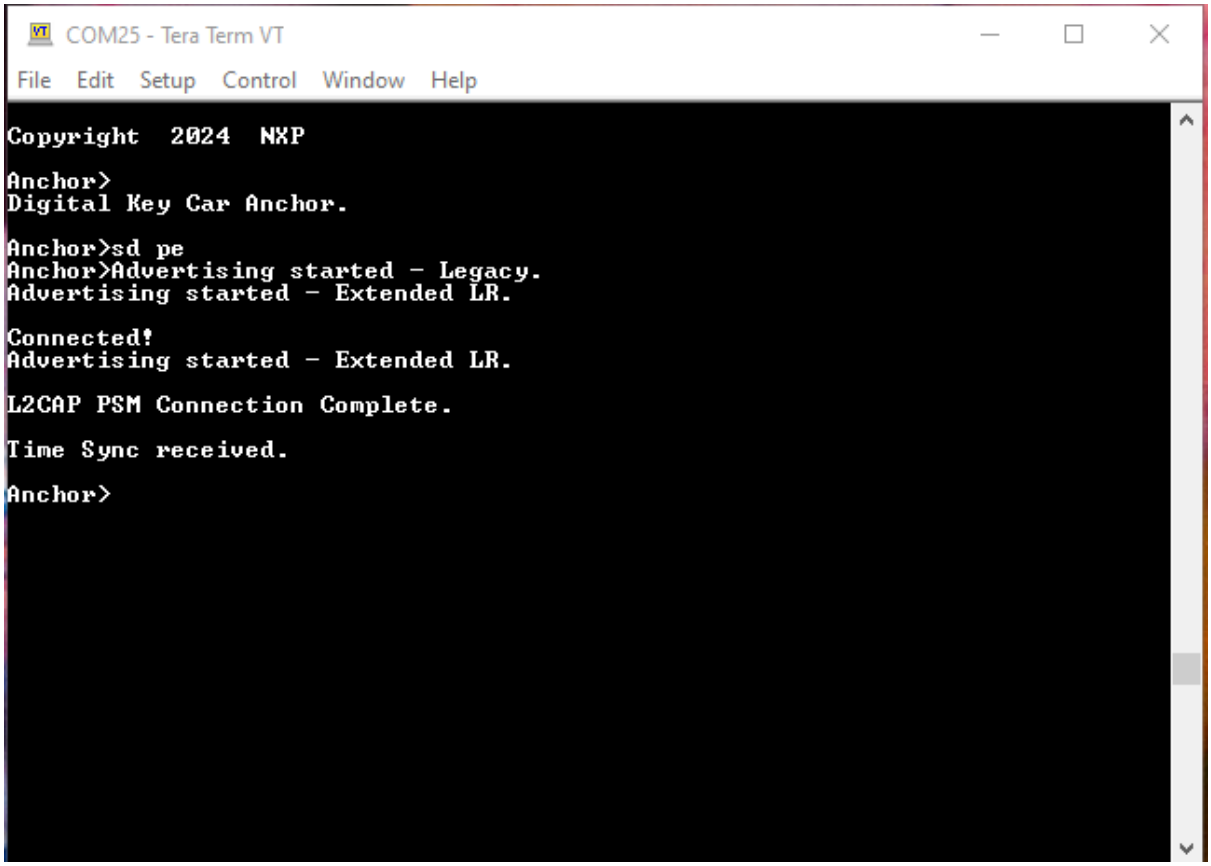
Owner Pairing on Device

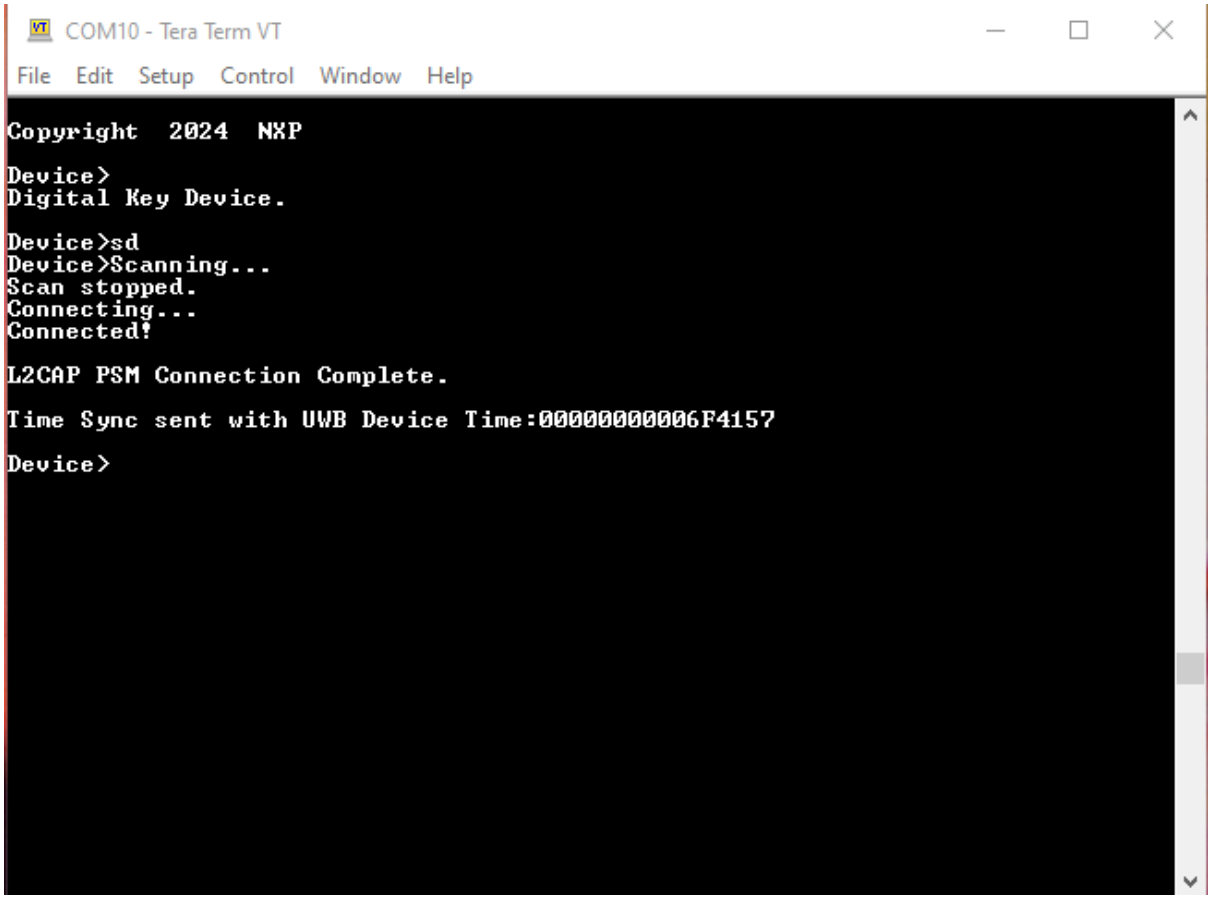
Parent topic:*Running CCC Digital Key scenarios using the Shell Interface*

Passive Entry Scenario



The Passive Entry scenario runs after Owner Pairing between a Car Anchor and a Device completes successfully.

To run the Passive Entry demo, first, reset the recently paired boards using either the **RST** switch or the "reset" command in the shell. Do NOT perform a factory reset, as this removes the bonding information from non-volatile memory.



After reset, run the "sd pe" command on the Car Anchor and "sd" command on the Device as shown in Figure 1 and Figure 2. For the Passive Entry scenario, the Car Anchor advertises using two sets, one Legacy on the 1M PHY and one Extended on the Coded PHY. If bonding data is present, it follows the Passive Entry flow and stops after the successful creation of the L2CAP channel. At this point the application is functional. The output of the command is shown in Figure 1 and Figure 2. Similar to the Owner Pairing scenario, the applications implement only the Bluetooth Low Energy functionality.

Note: The CCC specification requires using coding scheme S=2 for Coded PHY advertising, equivalent to a data rate of 500 Kbits per sec. To experiment with other coding schemes, change the advertising parameters in the app_config.c file for the digital_key_car_anchor project.

Passive Entry on Car Anchor

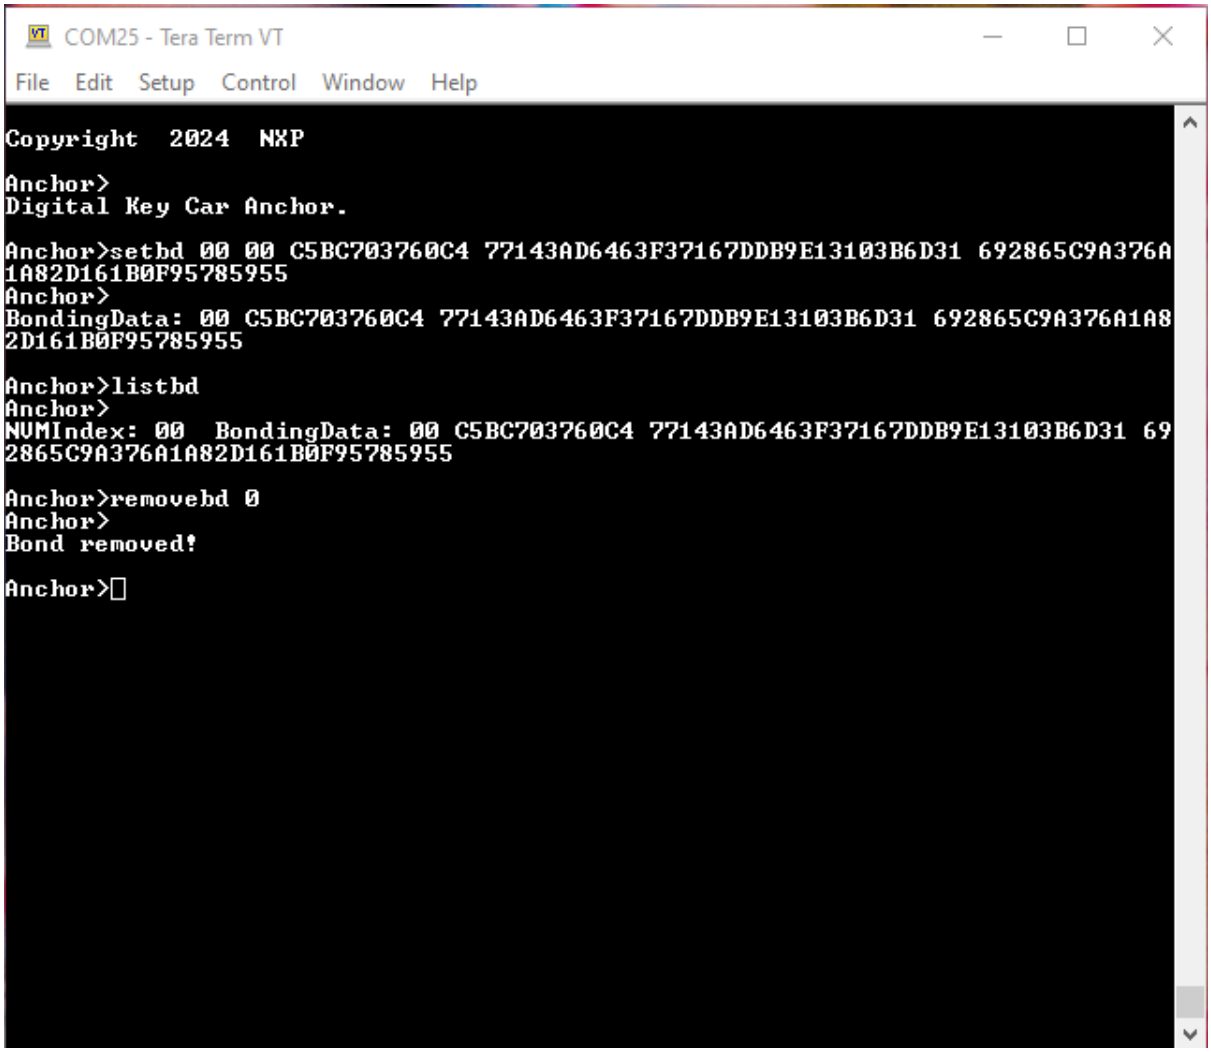
Passive Entry on Device

Parent topic:*Running CCC Digital Key scenarios using the Shell Interface*

Synchronizing bonding data between Car Anchors

Note: On the KW45B41Z-EVK, KW47-EVK and FRDM-KW43 platforms, this feature is only valid when Advanced Secure Mode is disabled (gAppSecureMode_d is set to 0 in the app_preinclude.h file). To synchronize bonding data when Advanced Secure Mode is enabled, refer to *Running the A2B scenario*.

Multiple Car Anchors can reside on a car, acting as a single Bluetooth Low Energy device as far as the Device is concerned. When the Device pairs and bonds with a Car Anchor, that bonding data must be shared with all other anchors. To showcase this functionality, the Car Anchor shell demo offers the "setbd" command.



During owner pairing, the bonding data is displayed in the shell as seen in the Owner Pairing section. By passing this data to the "setbd" command on another Car Anchor, that anchor is able to connect with the original Device and perform the Passive Entry flow.

Note: Currently only the Bluetooth Low Energy bonding data is transferred between anchors. No CCC Digital Key R3-specific keys are exchanged.

Saved bonding data can also be viewed using the "listbd" command and a specific bond can be removed using the "removebd" command. See Figure 1 for details.

A bond can only be removed if a connection to that specific device is not currently active. The commands presented in this subsection are also supported on the Device for test purposes.

Adding bonding data to a Car Anchor, listing bonds and removing a bond

Note:

- To simulate anchors residing on the same car, Random Static Address required by the Digital Key protocol and the Identity Resolving Key are set at compile time for the digital_key_car_anchor project. To simulate anchors residing on different cars, change the values of the APP_BD_ADDR and APP_SMP_IRK macros in the project's app_preinclude.h.

Parent topic:*Running CCC Digital Key scenarios using the Shell Interface*

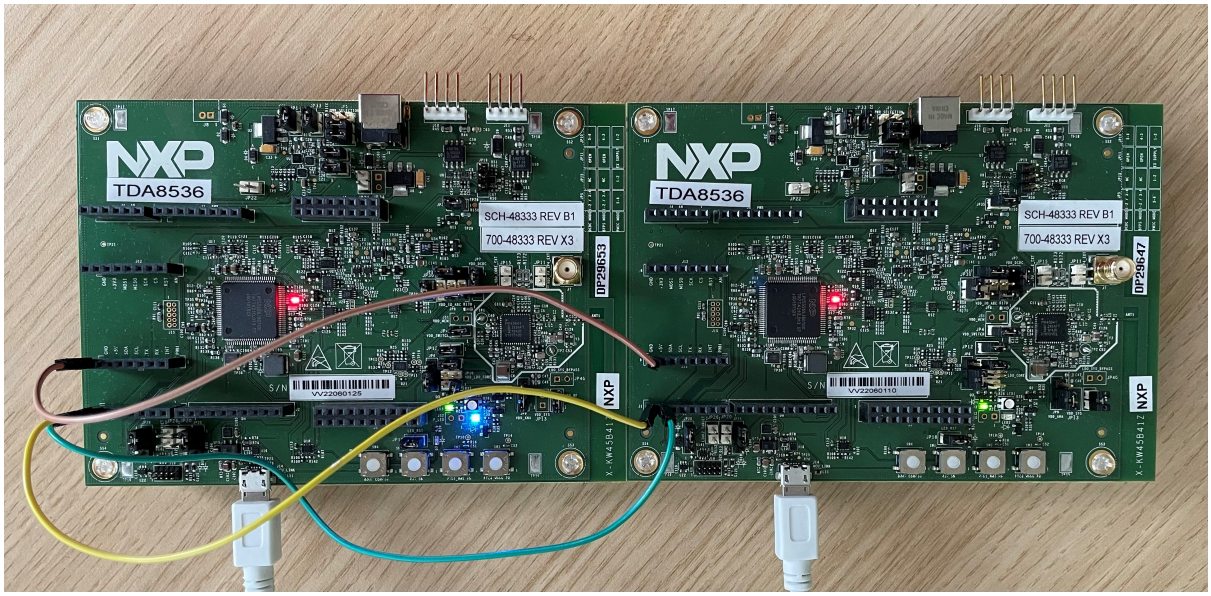
Connection with a non-CCC Key Fob Scenario

The Car Anchor also supports connecting as a Bluetooth Low Energy central device (scanner) to a non-CCC key fob (advertiser). To enable scanning on the digital_key_car_anchor project set the gAppScanNonCCC_d macro to 1 in the project's app_preinclude.h before building.

After flashing the board and running "factoryreset", run the "sd op" or "sd pe" command exactly as in the Owner Pairing or Passive Entry scenarios. The Car Anchor will simultaneously advertise for a CCC Device and scan for a non-CCC key fob.

Connection with the non-CCC key fob and the subsequent application functionality is currently out of this application note's scope.

Parent topic:*Running CCC Digital Key scenarios using the Shell Interface*



Running the Connection Handover scenario

Connection Handover is an NXP proprietary feature that enables a Bluetooth Low Energy connection to be seamlessly transferred from one peripheral to another while the central device remains unaware. It is best exemplified by (but not limited to) the CCC Digital Key use case. As a person carrying a phone moves around the vehicle, the Bluetooth Low Energy connection is transferred between Car Anchors in order to ensure the best user experience. From the Device's point of view, it stays in the same initial connection.

The CCC Digital Key demos showcase the Connection Handover feature. The handover is performed on demand via a button press. In a real scenario, the handover is performed based on criteria such as RSSI. The feature is currently supported on the KW45B41Z-EVK, KW47-EVK and FRDM-KW43 platforms.

Prerequisites:

- Three boards (two boards act as Car Anchors, one as a Device). The demo is currently limited to a maximum of two Car Anchors.
- The two Car Anchors must have a serial connection via the secondary UART as shown in the image below. The UART connection stands in for a real deployment solution such as a CAN bus.
- The *gHandoverDemo_d* macro must be set to 1 in app_preinclude.h for the ***digital_key_car_anchor*** project. Figure 1 shows KW45B41Z-EVK car anchors connected via secondary UART. *(J1-1 is connected to J1-2 and J1-2 is connected to J1-1. GND connection is J13-1 to J13-1.)*
- If KW47-EVK boards are used, make the UART connection between J1-1 to J1-3 and J1-3 to J1-1.
- If FRDM-KW43 boards are used, make the UART connection between JP19-1 (UART0_TX PTA17) to J22-1 (UART0_RX PTA18) and J22-1 to JP19-1. **Note:** The current firmware configuration uses PTA18 for UART0_RX instead of PTA16 as shown in the schematic. **Two Car Anchors connected via the secondary UART**

Demo steps:

- Connect a Car Anchor and a Device using either the Owner Pairing or Passive Entry scenario as detailed in the previous sections. If doing Owner Pairing, the bonding data synchronization between the two Car Anchors will happen automatically over the UART connection.
- Optional: Use the "send" shell command on the Car Anchor to send a test message over the L2CAP Credit-Based channel. The message is displayed in the console on the Device.
- Press the **SW3** switch or use the handover command with the peer device ID on the Car Anchor which is connected to the Device. To see a list of connected devices with their corresponding peer device IDs the listad command may be used.
- The connection is handed over to the second Car Anchor as seen in console messages. LED2 also turns solid blue on the Car Anchor, which has taken over the connection.
- **Optional**: Use the "send" shell command on the Car Anchor that has taken over the connection. The message is displayed in the console on the Device.
- The connection can continue to be handed over back and forth between the two Car Anchors by pressing the **SW3** switch on the Car Anchor which currently has the connection. Figure 2 shows first Car Anchor connects and pairs with the Device, sends the L2CAP test message and successfully performs handover when **SW3** is pressed.

Paring and connection of First Car Anchor with Device and handover

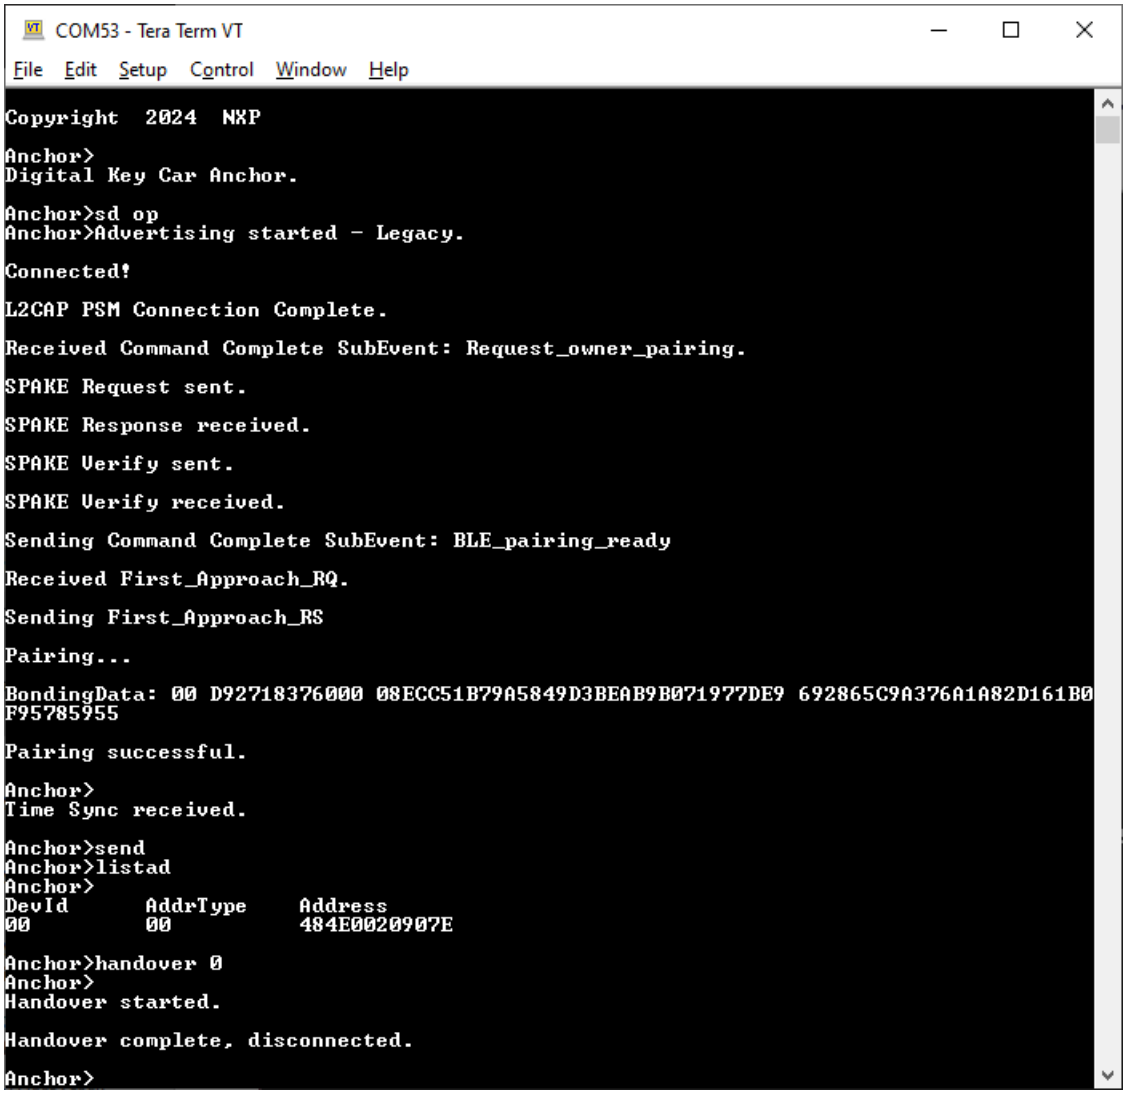


Figure 3 shows that the second Car Anchor receives the bonding data automatically via UART when the first Car Anchor pairs with the Device. After the handover is successfully completed, it sends the L2CAP test message to the Device.

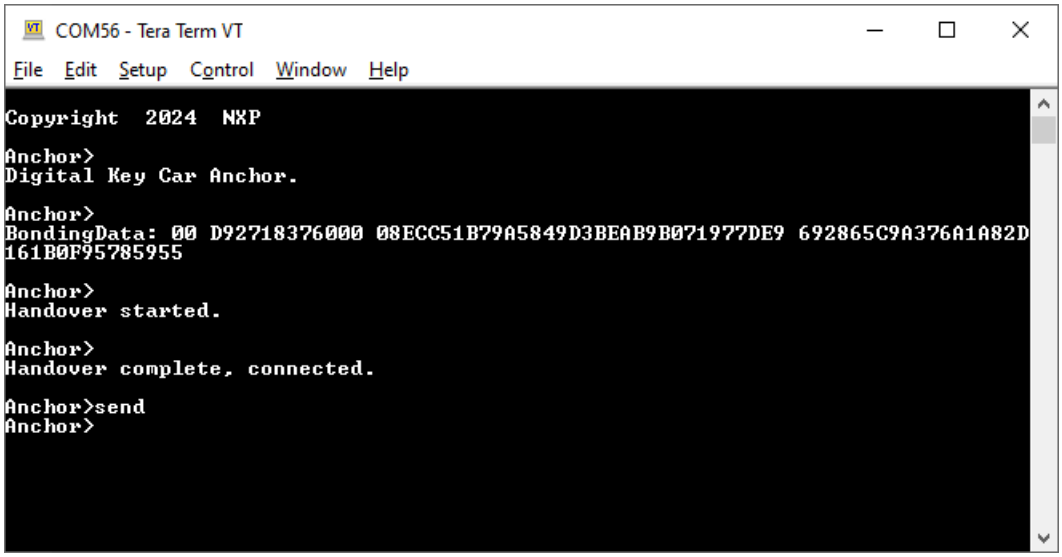
Second Car Anchor receiving the bonding data automatically via UART when the first Car Anchor pairs with the Device



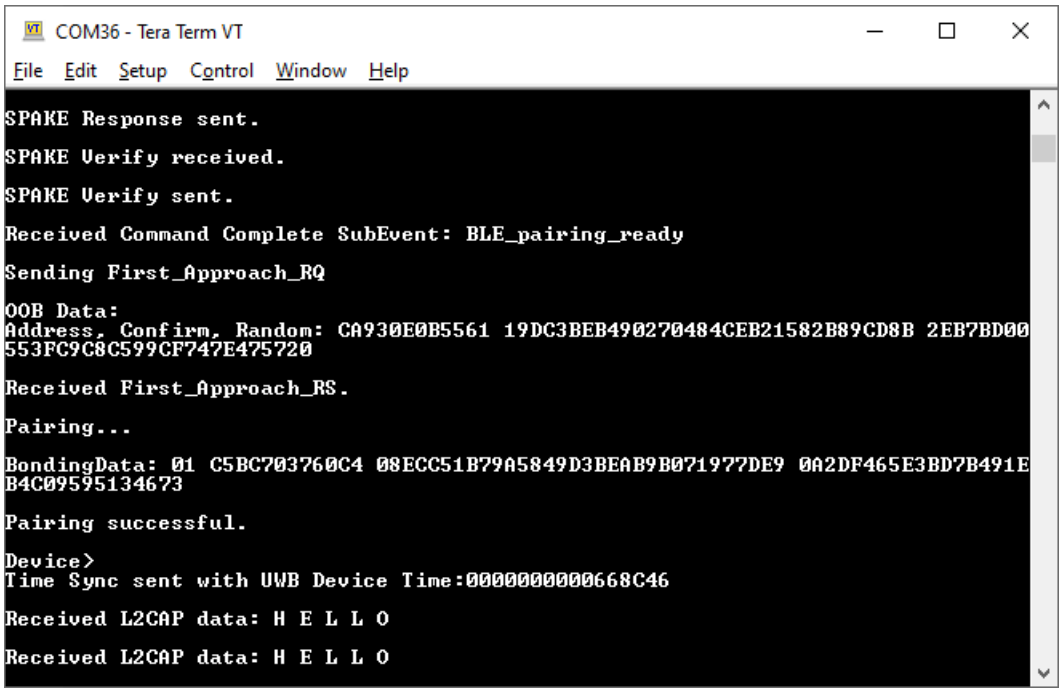


Figure 4 shows the Device receiving both L2CAP test messages. From the device's point of view, it is in a single uninterrupted connection.

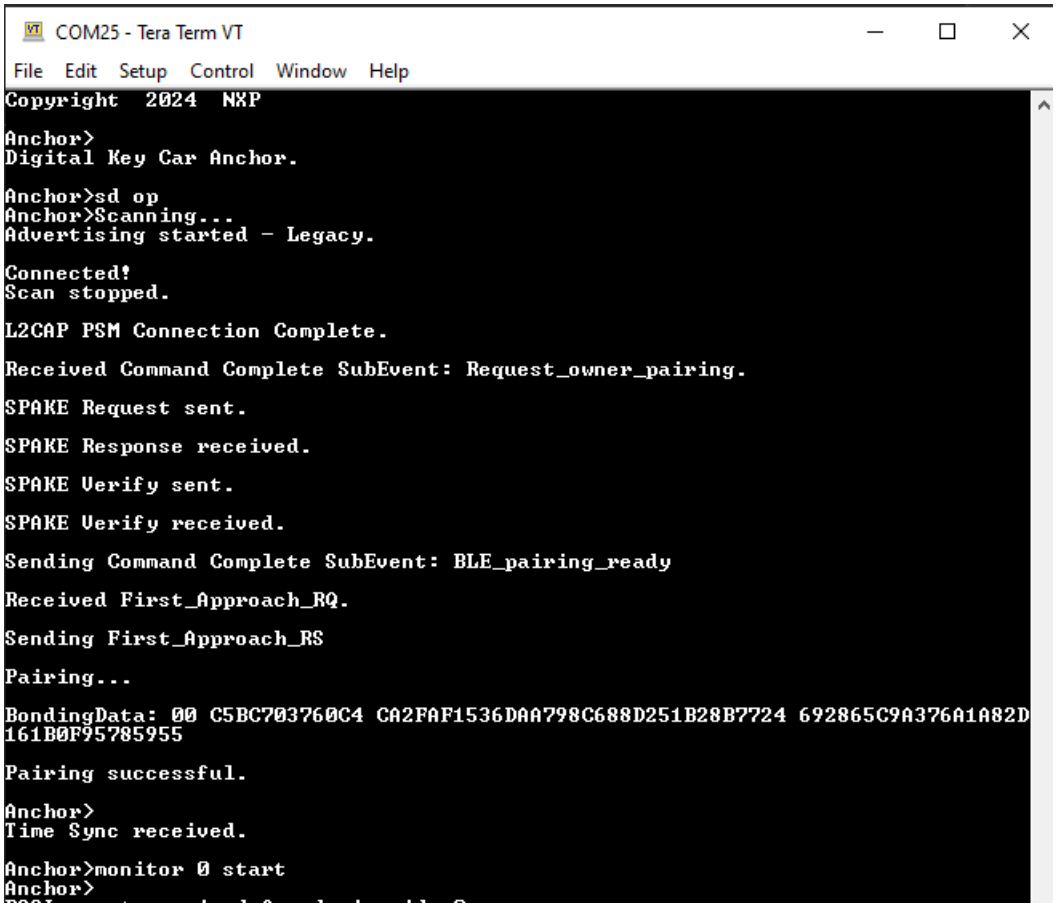
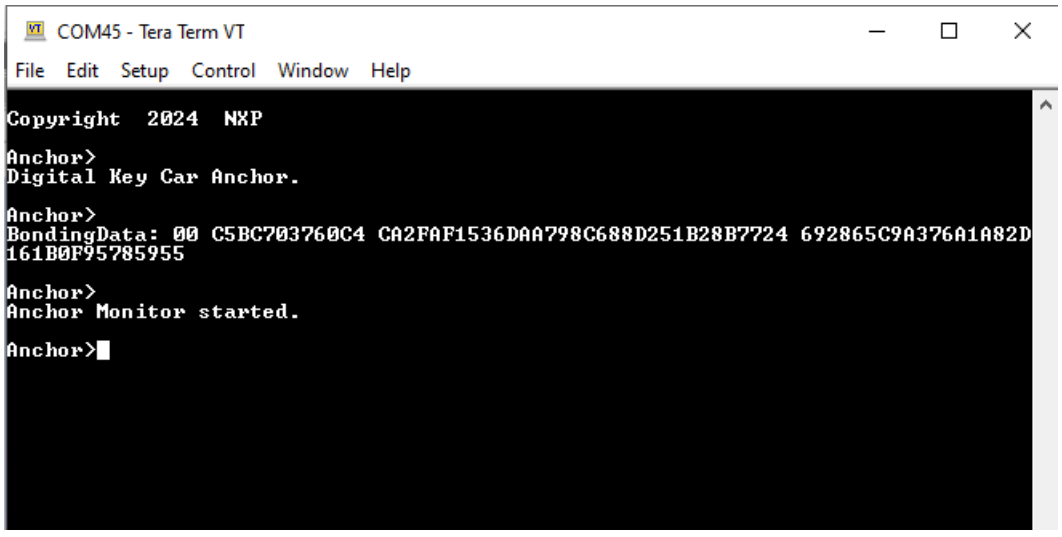
The Device receives both L2CAP test messages



Running the Anchor Monitoring scenario

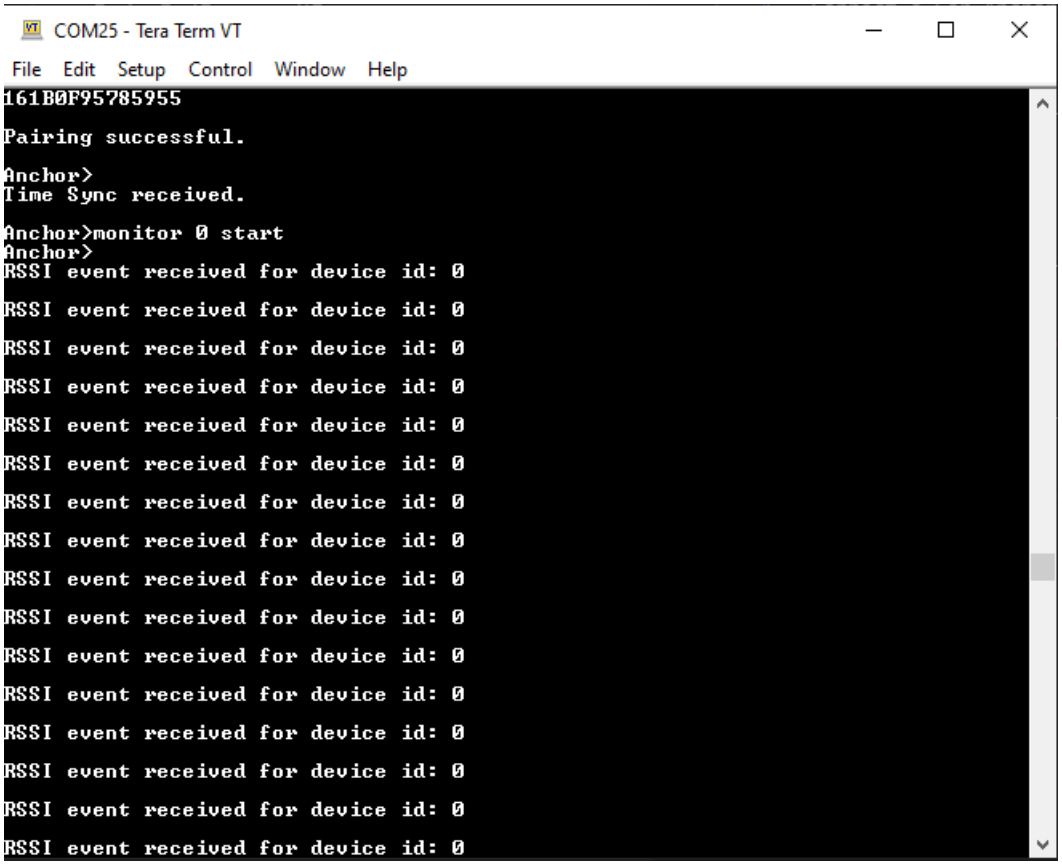
Anchor Monitoring is an NXP proprietary feature that allows a second Anchor to monitor the connection between the first Anchor and the Device. The prerequisites are the same hardware setup as used for the Connection Handover scenario. Note, however, that the Connection Handover scenario cannot be performed while Anchor Monitoring is in progress.

Demo steps:



1. Connect a Car Anchor and a Device using either the Owner Pairing or Passive Entry scenario as described in Owner Pairing Scenario and Passive Entry Scenario.

Anchor has performed Owner Pairing and the "monitor start" command is run



2. Run the "monitor 0 start" shell command on the Car Anchor, as seen in Figure 1.

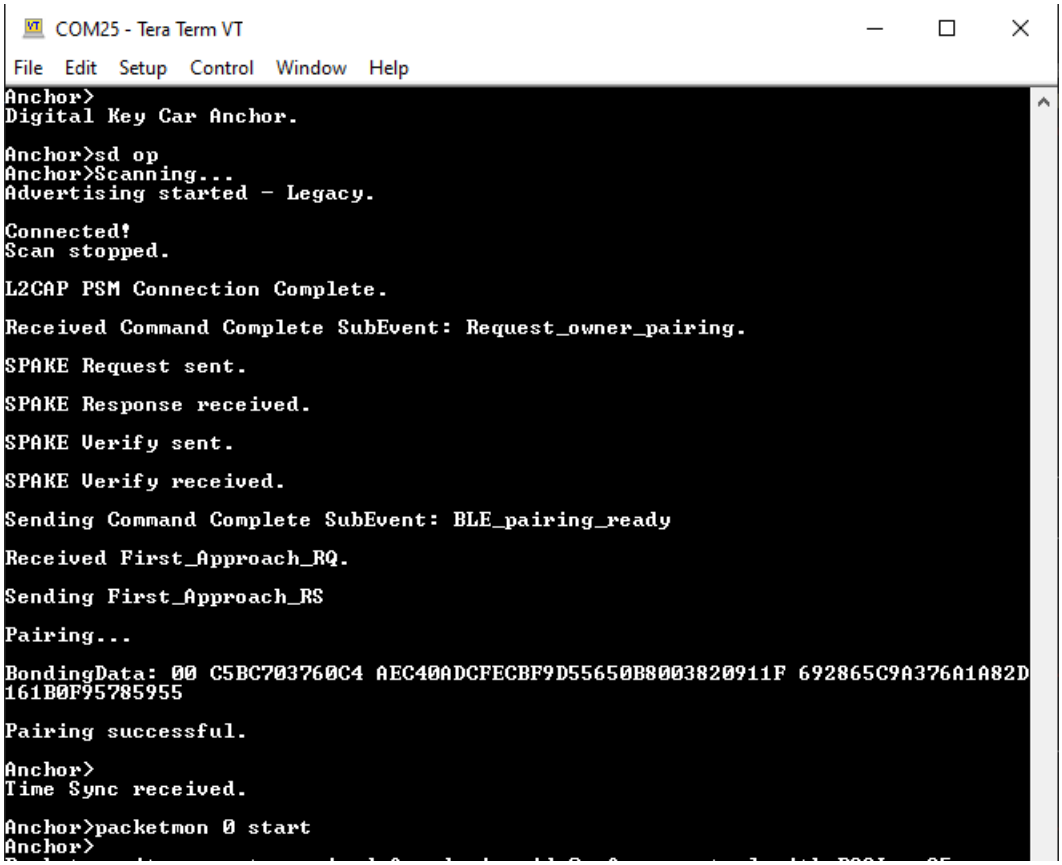
The second Anchor has received the command over the serial interface and has started Anchor Monitoring

3. The second Car Anchor begins monitoring the connection and receives RSSI info events, which it forwards to the first Car Anchor (see Figure 2).

The first Anchor displays RSSI events received from the second Anchor.

4. The received RSSI messages are displayed in the console (see Figure 3).
5. To stop monitoring, run the "monitor 0 stop" shell command on either Car Anchor (the second one is recommended, as its console is not flooded by RSSI event messages).

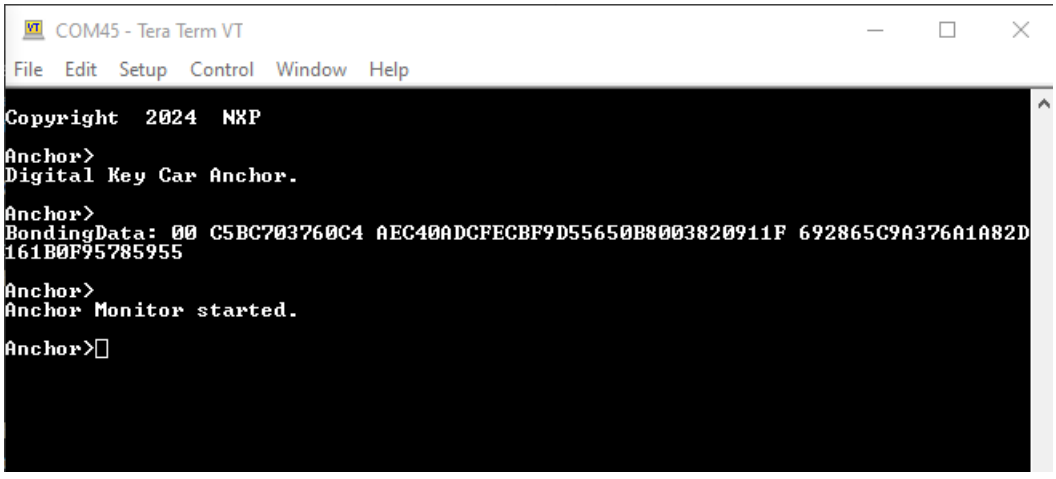
Parent topic:*Running the Connection Handover scenario*



Running the Packet Monitoring scenario

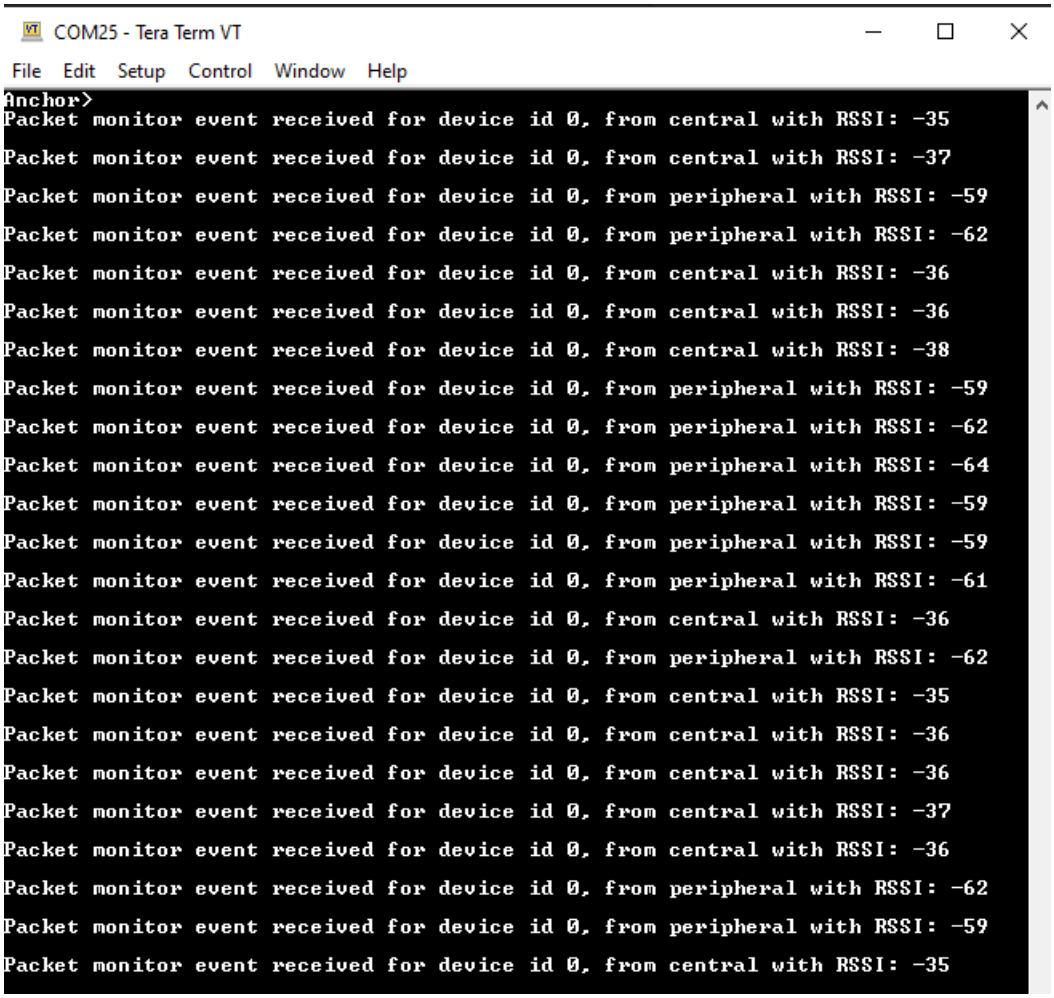
Packet Monitoring is an NXP proprietary feature that allows a second Anchor to receive the packets from the connection between the first Anchor and the Device. The prerequisites are the same hardware setup as used for the *Running the Connection Handover scenario*. Note, however, that the Connection Handover scenario cannot be performed while Packet Monitoring is in progress. Packets received by the second Anchor are sent over the serial interface to the first Anchor for processing. The first Anchor determines the source of the packet based on bit 1 of the status parameter, which indicates whether the packet was sent by the central (1) or the peripheral (0), and displays the RSSI.

Demo steps:



1. Connect the first Anchor and a Device using either the Owner Pairing or Passive Entry scenario as described in Owner Pairing Scenario and Passive Entry Scenario.

Anchor has performed Owner Pairing and the "packetmon start" command is run



2. Run "packetmon 0 start" on the first Anchor, as shown in Figure 1.

The second Anchor has received the command over the serial interface and has started Packet Monitoring

3. The second Anchor begins monitoring the connection and receives packet information, which it forwards to the first Anchor. See Figure 2.

The first Anchor displays the RSSI and source device of the received packets from the second Anchor

4. The first Anchor receives the packet information from the second Anchor and determines the source of the packet based on bit 1 of the `status` parameter, which indicates whether the packet was sent by the central (`1`) or the peripheral (`0`). The source and the RSSI are displayed in the console. See Figure 3.
5. To stop monitoring, run "`packetmon 0 stop`" shell command on either Anchor (the second one is recommended, as its console is not flooded by packet information messages).

Parent topic:*Running the Connection Handover scenario*

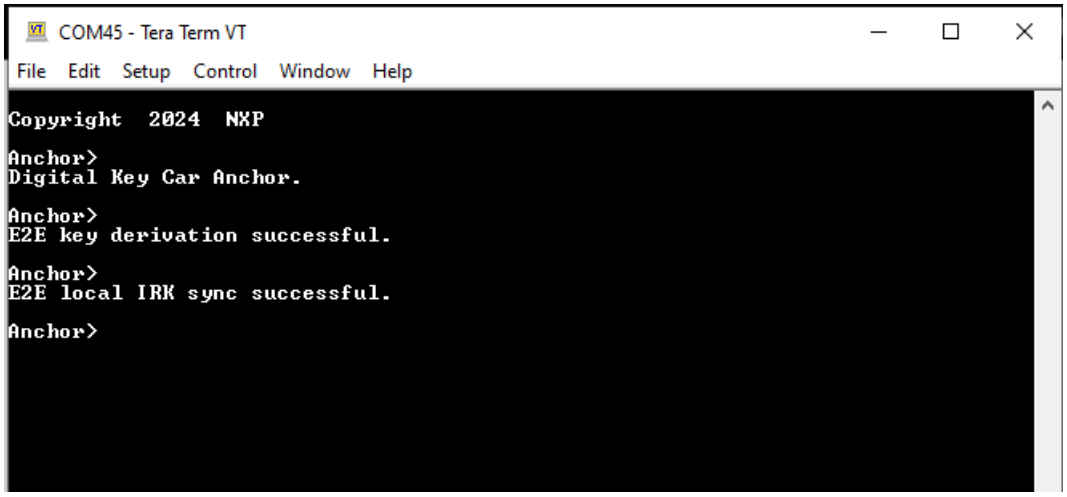
Running the A2B scenario

The A2B feature allows for the secure transfer of Bluetooth Low Energy security keys information between the Car Anchor devices. The feature is currently supported on the following platforms:

- KW45B41Z-EVK with a lifecycle state of OEM-Open or higher, this feature is provided by the EdgeLock Secure Enclave.
- KW47-EVK with a lifecycle state of OEM-Open or higher, this feature is provided by th EdgeLock Secure Enclave.
- FRDM-KW43 with a lifecycle state of OEM-Open or higher, this feature is provided by the EdgeLock Secure Enclave.

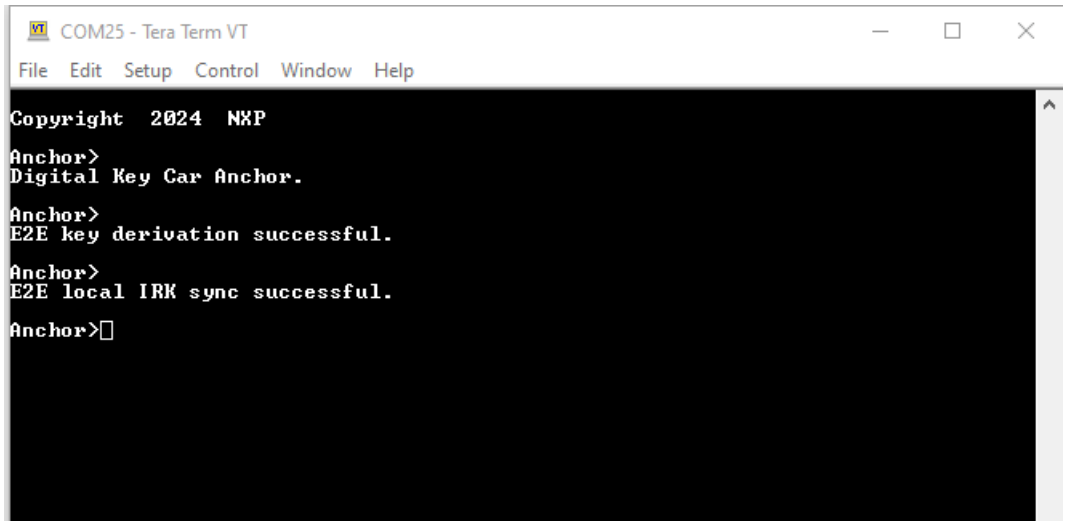
The Car Anchor demo application makes use of the A2B feature to securely synchronize the local IRK and the Bonding Data (LTK and peer IRK) with another Car Anchor.

Prerequisites:



- Three boards (two act as Car Anchors, one as a Device). The demo is currently limited to a maximum of two Car Anchors.

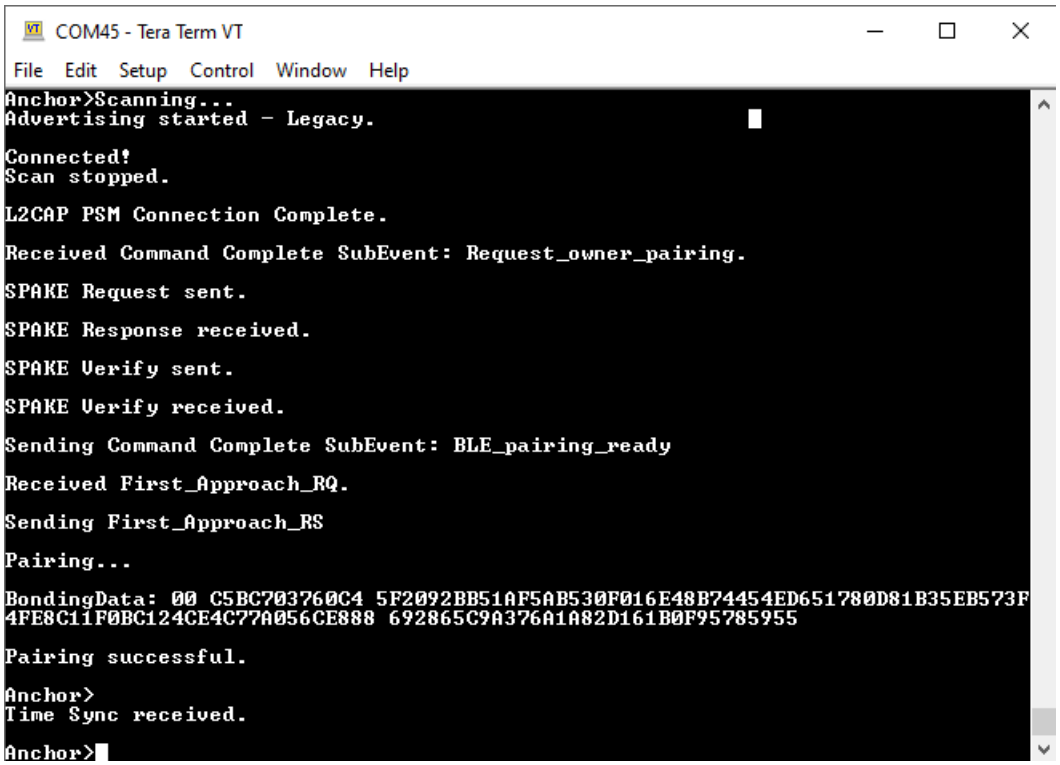
- The two Car Anchors must be connected via a serial interface as described in the section above.
- Advanced Secure Mode must be enabled. The following macros must be defined and set to 1 in app_preinclude.h for the ***digital_key_car_anchor*** project:
  - gAppSecureMode_d
  - gA2BEnabled_d
- One of the Car Anchors must be configured with the gA2BInitiator_d macro set to 1, this is called Car Anchor A, and the other must be configured with the gA2BInitiator_d macro set to 0, called Car Anchor B. Car Anchor A triggers the EdgeLock-to-EdgeLock (E2E) key derivation and local IRK synchronization. Therefore, it should be started up after Car Anchor B.



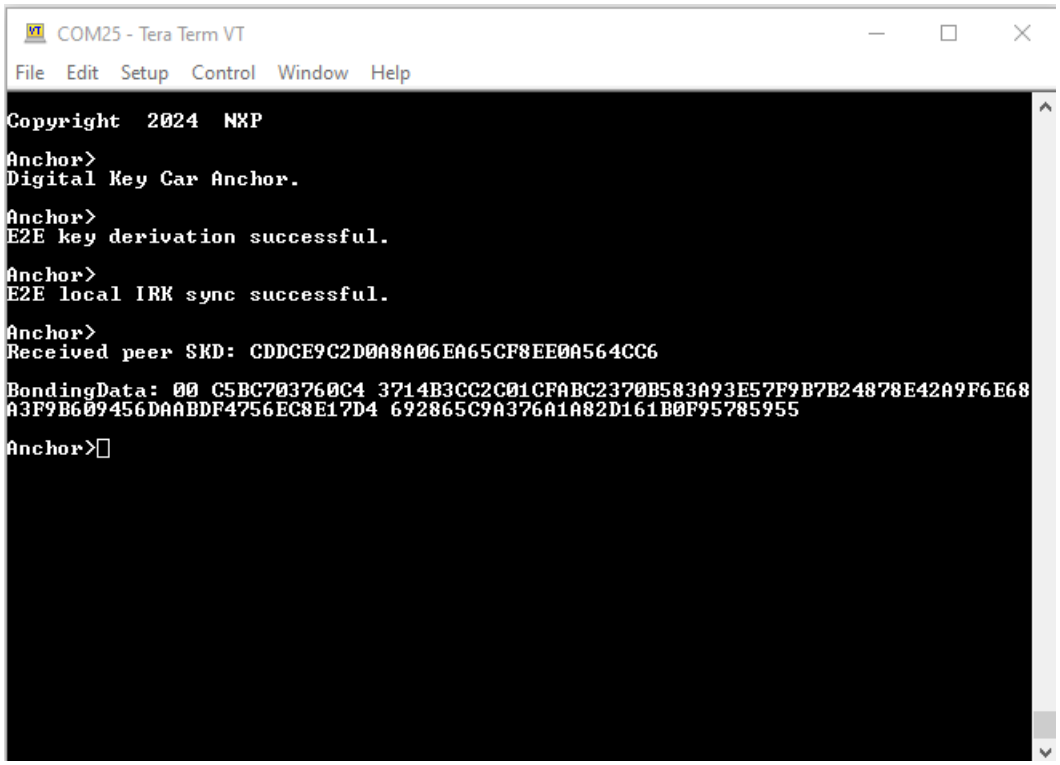
Demo steps:

- Start Car Anchor B, then Car Anchor A. At initialization the E2E key is derived and the local IRK of Car Anchor A is sent as a secure blob to Car Anchor B in order for both Car Anchors to have the same local IRK as shown in the Figure 1 and Figure 2.

Car Anchor A starts up, derives the E2E key and syncs with Car Anchor B



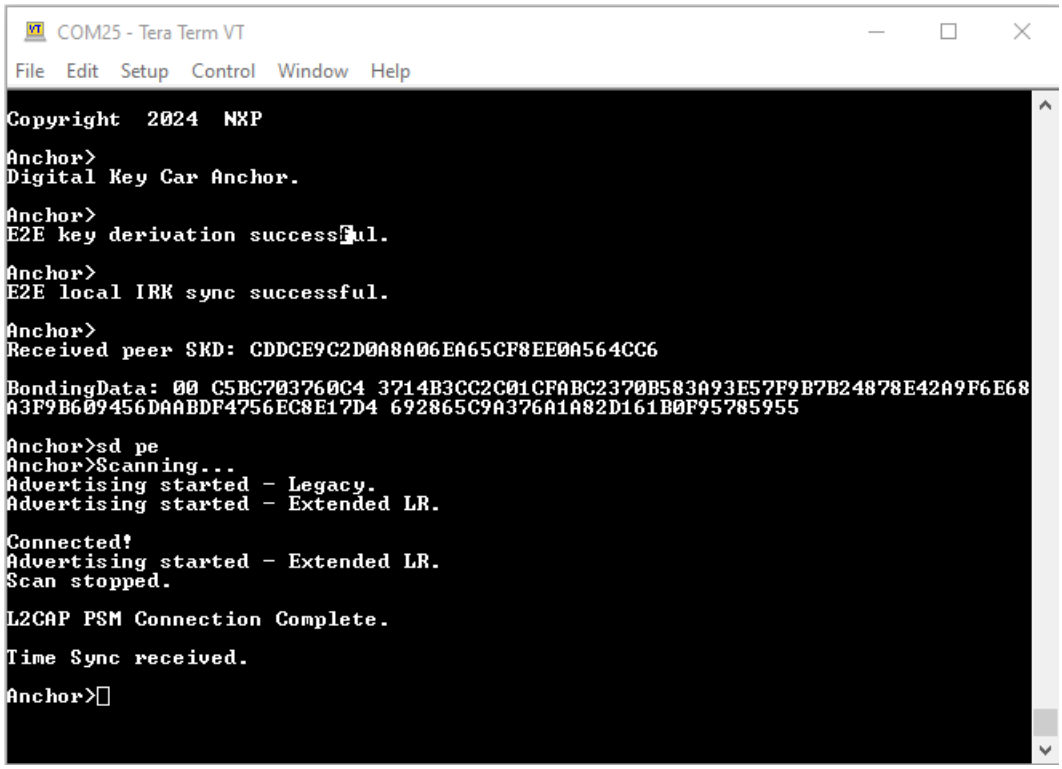
Car Anchor B starts up and syncs with Car Anchor B



- Trigger the Owner Pairing scenario by sending the "sd" command on the Device and "sd op" on Car Anchor A. Once the bond is created, the Bonding Data containing secured blobs for the LTK and peer IRK is sent to Car Anchor B. The Car Anchors display the Bonding Data in shell with the LTK in blob form (the LTK is never available in plain text) and the peer IRK in

plain text. Now both Car Anchors have the same Bonding Data. Refer Figure 3 and Figure 4.

Car Anchor A pairs with Device



Car Anchor B has received the Bonding Data via the serial interface

- Disconnect Car Anchor A by sending the "dcnt" command.
- Once Car Anchor A is disconnected, send "sd" on the Device and "sd pe" on Car Anchor B. Car Anchor B is now able to perform a Passive Entry connection, without pairing as shown

in Figure 5.

Car Anchor B performs Passive Entry

Running Passive Entry Scenario with Decision Based Advertising Filtering (DBAF)

Decision Based Advertising Filtering can be used in the Passive Entry scenario. Using DBAF optimizes the scanning operation performed by the Digital Key Device of the advertisements sent by the Digital Key Car Anchor devices. This is accomplished by using 'ADV_DECISION_IND' PDUs, which contain the advertising address in the extended header. Using these PDUs allows the scanner to perform address resolution without the need to retrieve the AUX_ADV_IND PDU sent on the data channels.

The DBAF feature is supported on the following platforms:

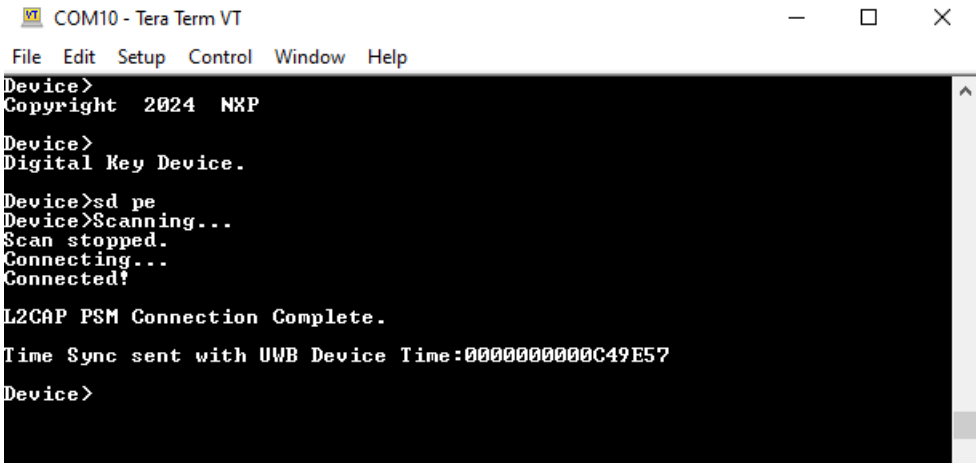
- KW45B41Z-EVK
- KW47-EVK
- FRDM-KW43

Enabling DBAF

To enable DBAF, modify the Digital Key applications as per the steps listed below:

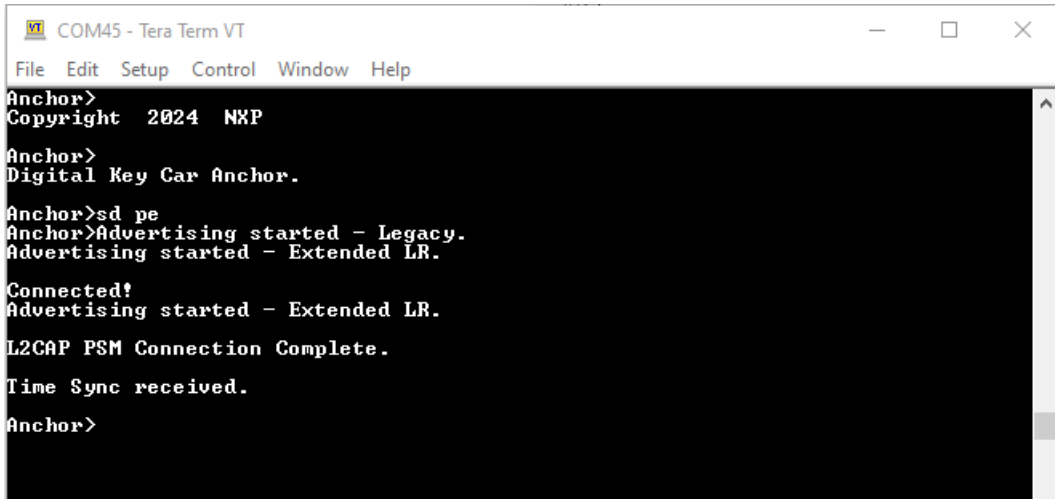
- In app_preinclude.h file, set gBLE60_DecisionBasedAdvertisingFilteringSupport_d to 1.

Parent topic:*Running Passive Entry Scenario with Decision Based Advertising Filtering (DBAF)*



Running the Passive Entry with DBAF scenario

The Passive Entry with DBAF scenario runs after Owner Pairing between a Car Anchor and a Device successfully completes.



1. To run the Passive Entry with DBAF demo, reset the recently paired boards using either the **RST** switch or the "reset" command in the shell. Do NOT perform a factory reset, as this removes the bonding information from non-volatile memory.

2. After reset, run the "sd pe" command on the Car Anchor and "sd pe" command on the Device as shown in Figure 1 and Figure 2.

Passive Entry with DBAF on Device

Passive Entry with DBAF on Car Anchor

After following these steps, the Passive Entry scenario as described in Passive Entry Scenario runs.

Parent topic:*Running Passive Entry Scenario with Decision Based Advertising Filtering (DBAF)*

Intrusion Detection System

The Intrusion Detection System (IDS) is a proprietary feature which allows the Car Anchor to monitor anomalous events related to the traffic and conditions generated during the operation of the Bluetooth LE software stack. These events are detected at Host and Controller level. The application registers a callback where it receives and handles reports.

The IDS feature is supported on the following platforms:

- KW45B41Z-EVK
- KW47-EVK
- FRDM-KW43

To enable IDS, modify the Digital Key Car Anchor as per the steps listed below:

- In app_preinclude.h file, set gIntrusionDetectionSystem_d to 1.

Intrusion Detection System Test Mode

The IDS Test Mode is a development and testing feature that allows developers to simulate and validate IDS security event detection without requiring actual attack scenarios or malicious devices.

Enabling Test Mode

To enable IDS Test Mode, set gIntrusionDetectionSystemTestMode_d to 1 in app_preinclude.h.

This enables:

- Shell command idstest for triggering security events
- Pairing message interception hooks
- Test packet generation utilities

Supported Security Events

IDS Test Mode supports triggering the following security events:

Bit	Event Macro	Description	Category	Trigger Method
0	gSecEvt_Sweyntooth_MaxEncKeyS	Max Encryption Key Size (Sweyntooth)	Pairing	Hook
1	gSecEvt_DhKeyCheckZero_c	DH Key Check Zero	Pairing	Hook
2	gSecEvt_UnexpectedSmpMessage_	Unexpected SMP Message	Pairing	Hook
5	gSecEvt_MicFailureDisconnect_c	MIC Failure Disconnect	Connection	Packet
6	gSecEvt_EncReqNonBonded_c	Non-Bonded Device	Connection	Packet
7	gSecEvt_MalformedL2cap_c	Malformed L2CAP Packet	Connection	Packet
8	gSecEvt_MalformedAtt_c	Malformed ATT Packet	Connection	Packet
13	gSecEvt_ForcedRepairing_c	Forced Re-pairing	Pairing	Hook
14	gSecEvt_L2capFragmentsExceedMT	L2CAP Fragments Exceed MTU (Blue Frag)	Connection	Packet
16	gSecEvt_KNOB_c	Key Negotiation over Bluetooth (KNOB)	Pairing	Hook
18	gSecEvt_InvalidPublicKey_c	Invalid Public Key	Pairing	Hook
19	gSecEvt_WrongConfirmValue_c	Wrong Confirm Value	Pairing	Hook
20	gSecEvt_DHKeyCheckFailed_c	DH Key Check Failed	Pairing	Hook

Event Categories

Connection Events (Immediate Trigger)

These events are triggered immediately when the idstest command is executed:

- **BIT5**: MIC Failure Disconnect
- **BIT7**: Malformed L2CAP Packet
- **BIT8**: Malformed ATT Packet
- **BIT14**: L2CAP Fragments Exceed MTU

BIT6: Encryption Request from Non-Bonded Device

Natural Scenario:

1. Connect device to anchor with bonding enabled
2. Complete pairing and bonding successfully
3. Disconnect device
4. On anchor: Run factoryreset command
5. On device: Reconnect without clearing bonds
6. IDS event triggers when device sends encryption request

Pairing Events (Hook-based Trigger)

These events activate a message interception hook and trigger during the next pairing procedure:

- **BIT0**: Sweyntooth Max Encryption Key Size
- **BIT1**: DH Key Check Zero
- **BIT2**: Unexpected SMP Message
- **BIT13**: Forced Re-pairing
- **BIT16**: KNOB (Key Negotiation)
- **BIT18**: Invalid Public Key
- **BIT19**: Wrong Confirm Value
- **BIT20**: DH Key Check Failed

Using the idstest Command

idstest <event_bit> [device_id]

Examples

Trigger Connection Event (Immediate):

```
Anchor> idstest 5 0
[IDS TEST] Event BIT5 (mask 0x20000000) triggered for device 0.
Anchor> Received IDS event 32 triggered by peer 25008F195173
```

Trigger Pairing Event (During Next Pairing):

```
Anchor> idstest 0 0
[IDS TEST] Pairing event BIT0 (mask 0x00000001) will be triggered on next pairing.
[IDS TEST] Hook activated. Now run 'sd op' to start Owner Pairing.

Anchor> sd op
Advertising started - Legacy.
Connected!
Received IDS event 65536 triggered by peer 1BE0914D955A
```

Bluetooth Low Energy Host Stack FSCI Application Programming Kinetis FSCI Host Application Programming Interface

About This Document

This document provides a detailed description for the Host Application Programming Interface (Host API) implementing the Framework Serial Connectivity Interface (FSCI) on a peripheral port such as UART, USB, and SPI. The Host API can be deployed from a PC tool or a host processor to perform control and monitoring of a wireless protocol stack running on the microcontroller. The software modules and libraries implementing the Host API is the Host Software Development Kit (SDK).

This version of the document describes the Bluetooth® Low Energy stack running on the Wireless Connectivity Microcontrollers (MCUs), which are interfaced from a high-level OS (Linux® OS, Windows® OS) by the Host API and the Host SDK.

Audience

This document is for software developers who create tools and multichip partitioned systems using a serial interface to a Bluetooth LE *black box* firmware running on a microcontroller.

Parent topic: *Bluetooth Low Energy Host Stack FSCI Application Programming*

Deploying Host Controlled Firmware

IAR Embedded Workbench for Arm® (EWARM) and ARMGCC are the development toolchains used to deploy the Bluetooth LE host stack software applications.

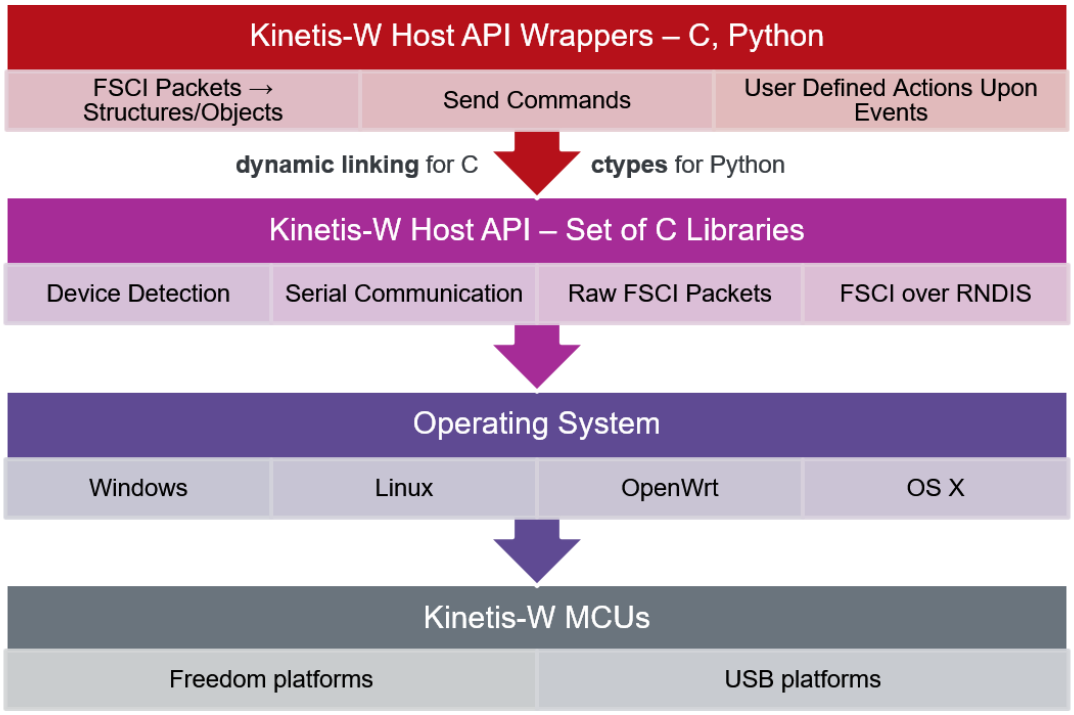
Detailed information about how to build, deploy and debug an IAR or ARMGCC-based project are presented in the *Bluetooth Low Energy Demo Applications User Guide*.

Bluetooth LE application configuration

To exercise the Host API, the Bluetooth LE *black box* firmware is required to be flashed on a compatible platform. The Bluetooth LE *black box* is represented by the ble_fscibb application firmware that can be interfaced and configured with FSCI commands over the serial interface.

The user can compile the *black box* image of the ble_fscibb software application using IAR Embedded Workbench for Arm (EWARM) or ARMGCC. For information on how to build the application see additional documentation provided in the package.

Parent topic: *Bluetooth Low Energy Host Stack FSCI Application Programming*



Host Software Overview

The FSCI (Framework Serial Communication Interface) module allows interfacing the protocol stack with a host system or PC tool using a serial communication interface.

FSCI can be demonstrated using various host software, one being the set of Linux OS libraries exposing the Host API described in this document. The NXP Test Tool for Connectivity Products PC application is another interfacing tool, running on the Windows OS. Bluetooth LE stack makes use of XML files which contain detailed meta-descriptors for commands and events transported over the FSCI.

The FSCI module is explained in the Wireless Framework - Services - FSCI documentation.

Device detection

The Wireless Host SDK can detect every USB attached peripheral device to a PC. On Linux OS, this is done via udev. Udev is the device manager for the Linux OS kernel and was introduced in Linux OS 2.5. Using the manager, the Wireless Host API can provide the Linux OS path for a device (for example, /dev/ttyACM0) and whether the device is a supported USB device, based on the vendor ID/product ID advertised. Upon device insertion, the USB cdc_acm kernel module is triggered by the kernel for interaction with TWR, USB and FRDM devices.

On Windows OS, attached peripherals are retrieved from the registry path HKEY_LOCAL_MACHINE\HARDWARE\DEVICEMAP\SERIALCOMM, resulting in names such as *COMxx* which must be used as input strings for the Python scripts which require a device name.

Serial port configuration

The Host SDK configures a serial UART port with the following default values:

Host SDK – UART default values

Configuration	Value
Baudrate	115200
ByteSize	EIGHTBITS
StopBits	ONE_STOPBIT
PARITY	NO_PARITY
HandleDSRControl	0
HandleDTRControl	ENABLEDTR
HandleRTSControl	ENABLERTS
InX	0
OutCtsFlow	1
OutDSRFlow	1
OutX	0

The library only allows the possibility to change the baudrate, as this is the most common scenario.

> **NOTE**: For devices using a USB connection interfaced directly (where the USB stack runs on the device and the system is NOT using an OpenSDA UART to USB converter), the baudrate is not necessary and setting it has no effect.

The Host SDK configures a serial SPI port with the following default values:

Host SDK – SPI default values

Configuration	Value
Transfer Mode	Mode SPI_MODE_0
Maximum SPI transfer speed (Hz)	1 MHz
Bits per word	8

The library only allows the possibility to change the maximum SPI transfer speed.

Logger

The Host SDK implements a logger functionality which is useful for debugging. Adding the compiler flag USE_LOGGER enables this functionality.

When running programs that make use of the Host SDK, a file named hsdk.log appears in the working directory. This is an excerpt from the log:

```
HSDK_INFO - [6684] [PhysicalDevice]InitPhysicalDevice:Allocated memory for PhysicalDevice
HSDK_INFO - [6684] [PhysicalDevice]InitPhysicalDevice:Initialized device's message queue
HSDK_INFO - [6684] [PhysicalDevice]InitPhysicalDevice:Created event manager for device
HSDK_INFO - [6684] [PhysicalDevice]InitPhysicalDevice:Created threadStart event

HSDK_INFO - [6684] [PhysicalDevice]AttachToConcreteImplementation:Attached to a concrete␣
↪implementation
HSDK_INFO - [6684] [PhysicalDevice]InitPhysicalDevice:Created and start device thread
HSDK_INFO - [6684] [Framer]InitializeFramer:Allocated memory for Framer
HSDK_INFO - [6684] [Framer]InitializeFramer:Created stopThread event
HSDK_INFO - [6684] [Framer]InitializeFramer:Initialized framer's message queue
HSDK_INFO - [6684] [Framer]InitializeFramer:Created event manager for framer
```

Parent topic: *Bluetooth Low Energy Host Stack FSCI Application Programming*

Linux OS Host Software Installation Guide

Libraries

Prerequisites

Packages: build-essential, libudev, libudev-dev, libpcap, libpcap-dev. Use apt-get install on Debian-based distributions. The Linux OS kernel version must be greater than 3.2.

Installation

```
$ pwd
/home/user/hsdk
$ make
$ find build/ -name "\*.so"
build/libframer.so
build/libsys.so
build/libphysical.so
build/libuart.so
build/libfsci.so
build/libspi.so
$ sudo make install
```

By default, make generates sharedlibraries (having .so extension). The step make install (superuser privileges required) copies these libraries to /usr/local/lib, which is part of the default Linux OS library path. The installation prefix may be changed by passing the variable PREFIX, e.g. make install PREFIX=/usr/lib. The user is responsible for making sure that PREFIX is part of the system's LD_LIBRARY_PATH.

Static libraries can be generated instead, by modifying the LIB_OPTION variable in the Makefile from dynamic to static (.a extension).

make install also disables the ModemManager control for the connected devices. Otherwise, the daemon starts sending AT commands that affect the responsiveness of the afore-mentioned devices in the first 20 seconds after plug in.

Demos

Installation

```
$ pwd
/home/user/hsdk/demo
$ make
$ ls bin/
GetKinetisDevices
```

These demos are provided in this package:

- GetKinetisDevices: this program detects the boards connected to the serial line and outputs the path to the console:

  ```
  $ ./GetKinetisDevices
  NXP Kinetis-W device on /dev/ttyACM0.
  NXP Kinetis-W device on /dev/ttyACM1.
  ```

Parent topic: *Bluetooth Low Energy Host Stack FSCI Application Programming*

Windows OS Host Software Installation Guide

Libraries

Prerequisites

Microsoft Visual Studio® is required to build the host software. Open the solution file ConnectivityLibrary.sln and build it for either Win32 or x64, depending on your setup requirements. The output directory contains a file named HSDK.dll, which can be thought of as a bundle of all the

shared libraries from Linux OS, except for SPI (libspi.so). Currently, SPI interface to the board is not supported by the Windows host software.

Prebuilt HSDK.dll files are available under directory hsdk-python\lib.

Installation

The host software for the Windows OS is designed to work in a Python environment by contrast to the Linux OS where standalone C demos also exist.

Download and install the Python 3.10.x/32b package from Python Downloads. When customizing the installation options, check Add python.exe to Path.

Using prebuilt library

1. Depending on your Python environment architure (not Windows architecture) copy the appropriate HSDK.dll from hsdk-python\lib\[x86|x64]to \<Python Directory\>\DLLs.
2. Download and install Visual C++ Redistributable Packages for Microsoft Visual Studio, depending on the Windows architecture of your system (vcredist_x86.exe or vcredist_x64.exe) from Microsoft Visual C++ Redistributable latest supported downloads.
3. Download and install the Microsoft Visual C++ Compiler for Python as described in the python Windows Complilers.

Using local built library

1. Depending on your Python environment architure (not Windows architecture), build the appropriate Microsoft Visual Studio solution configuration and then copy HSDK.dll to \<Python Directory\>\DLLs.
2. Download and install the Microsoft Visual C++ Compiler for Python as described in the python Windows Complilers.

Optionally, copy the hsdk\res\hsdk.conf to \<Python Directory\>\DLLs to control the behavior of the FSCI-ACK synchronization mechanism.

Demos

See *Host API Python Bindings*.

Parent topic: *Bluetooth Low Energy Host Stack FSCI Application Programming*

Host API C Bindings

The Host SDK includes a set of C bindings to interface with a *black-box*. Bindings are generated from the matching FSCI XML file that is available in the stack software package under tools\wireless\xml_fsci. The bindings are designed to be platform agnostic, with a minimal set of OS abstraction symbols required for building. Thus, the files can be easily integrated on a wide range of host platforms.

Directory Tree

```
hsdk-c/
  demo
    HeartRateSensor.c      Source file that implements the Bluetooth LE Heart Sensor Profile.
    Makefile
  inc
    ble_sig_defines.h      Standard Bluetooth SIG UUID values.
    cmd_<name>.h           Generated from the matching FSCI <name>.xml file.
    os_abstraction.h       Provides OS dependent symbols for building the interface.
  README.md
  src
    cmd_<name>.c           Generated from the matching FSCI <name>.xml file.
```

(continues on next page)

(continued from previous page)

```
    evt_<name>.c            Generated from the matching FSCI <name>.xml file.
    evt_printer_<name>.c    Generated from the matching FSCI <name>.xml file.
```

Tests and examples

Tests and examples that make use of the C bindings are placed in the hsdk-c/demo directory. Example of usage:

```
$ cd hsdk-c/demo/
$ make
$ ./HeartRateSensor /dev/ttyACM0
[...]
--> Setup finished, please open IoT Toolbox -> Heart Rate -> HSDK_HRS
```

Development

Header file cmd_<name>.h is generated from the corresponding <name>.xml FSCI XML file.

- Enumerations

```
/* Indicates whether the connection request is issued for a specific device or for all the devices in the␣
↪White List - default specific device */
typedef enum GAPConnectRequest_FilterPolicy_tag {
    GAPConnectRequest_FilterPolicy_gUseDeviceAddress_c = 0x00,
    GAPConnectRequest_FilterPolicy_gUseWhiteList_c     = 0x01
} GAPConnectRequest_FilterPolicy_t;
```

- Structures

```
typedef PACKED_STRUCT GAPConnectRequest_tag {
    uint16_t ScanInterval;          // Scanning interval - default 10ms
    uint16_t ScanWindow;            // Scanning window - default 10ms
    GAPConnectRequest_FilterPolicy_t FilterPolicy;          // Indicates whether the connection␣
↪request is issued for a specific device or for all the devices in the White List - default specific device
    GAPConnectRequest_OwnAddressType_t OwnAddressType;      // Indicates whether the address␣
↪used in connection requests will be the public address or the random address - default public address
    GAPConnectRequest_PeerAddressType_t PeerAddressType;    // When connecting to a specific␣
↪device, this indicates that device's address type - default public address
    uint8_t PeerAddress[6];       // When connecting to a specific device, this indicates that device's␣
↪address
    uint16_t ConnIntervalMin;       // The minimum desired connection interval - default 100ms
    uint16_t ConnIntervalMax;       // The maximum desired connection interval - default 200ms
    uint16_t ConnLatency;           // The desired connection latency (the maximum number of␣
↪consecutive connection events the Slave is allowed to ignore) - default 0
    uint16_t SupervisionTimeout;    // The maximum time interval between consecutive over-the-air␣
↪packets; if this timer expires, the connection is dropped - default 10s
    uint16_t ConnEventLengthMin;    // The minimum desired connection event length - default 0ms
    uint16_t ConnEventLengthMax;    // The maximum desired connection event length - default␣
↪maximum possible, ~41 s
    bool_t usePeerIdentityAddress;  // TRUE if the address defined in the peerAddressType and␣
↪peerAddress is an identity address
} GAPConnectRequest_t;
```

- Container for all possible event types

```
typedef struct bleEvtContainer_tag {
    uint16_t id;
    union {
        [...]
        GAPConnectionEventConnectedIndication_t GAPConnectionEventConnectedIndication;
```

(continues on next page)

(continued from previous page)

```
        [...]
    } Data;
} bleEvtContainer_t;
```

- Prototypes for sending commands

```
memStatus_t GAPConnectRequest(GAPConnectRequest_t *req, void *arg, uint8_t fsciInterface);
```

Header file os_abstraction.h provides the required symbols for building the generated interface. When integrating in a project different that Host SDK, the user needs to provide the implementation for

```
void FSCI_transmitPayload (
    void *arg,              /* Optional argument passed to thefunction */
    uint8_t og,             /* FSCI operation group */
    uint8_t oc,             /* FSCI operation code */
    void *msg,              /* Pointer to payload */
    uint16_t msgLen,        /* Payload length */
    uint8_t fsciInterface   /* FSCI interface ID */
);
```

that creates and sends a FSCI packet (0x02 | og | oc | msgLen | msg | crc +- fsciInterface) on the serial interface. Source files cmd_<name>.c, evt_<name>.c and evt_printer_<name>.c are generated from the correspondent <NAME>.xml FSCI XML file.

- Functions that handle command serialization in cmd_<name>.c

```
memStatus_t GAPConnectRequest(GAPConnectRequest_t *req, void *arg, uint8_t fsciInterface) {
    /* Sanity check */
    if (!req)
    {
        return MEM_UNKNOWN_ERROR_c;
    }
    FSCI_transmitPayload(arg, 0x48, 0x1C, req, sizeof(GAPConnectRequest_t), fsciInterface);
    return MEM_SUCCESS_c;
}
```

- Event dispatcher in evt_<name>.c

```
void KHC_BLE_RX_MsgHandler(void *pData, void *param, uint8_t fsciInterface) {
    if (!pData || !param)
    {
        return;
    }

    fsciPacket_t *frame = (fsciPacket_t *)pData;
    bleEvtContainer_t *container = (bleEvtContainer_t *)param;
    uint8_t og = frame->opGroup;
    uint8_t oc = frame->opCode;
    uint8_t *pPayload = frame->data;
    uint16_t id = (og << 8) + oc, i;

    for (i = 0; i < sizeof(evtHandlerTbl) / sizeof(evtHandlerTbl[0]); i++)
    {
        if (evtHandlerTbl[i].id == id)
        {
            evtHandlerTbl[i].handlerFunc(container, pPayload);
            break;
        }
    }
}
```

- Handler functions to perform event de-serialization in evt_<name>.c

```

Host API Python Bindings

Prerequisites

Python 3.10.x/32b is necessary to run the Python bindings. The bindings use the Host API C libraries. On Linux and OS X operating systems, these are called from the installation location which is /usr/local/lib, while on Windows OS the library file is loaded in <Python Install Directory>\DLLs.

Platform setup

To run scripts from the command line, the PYTHONPATH must be set accordingly, so that the interpreter can find the imported modules.

Linux OS

Adding the source folder to the PYTHONPATH can be done by editing ~/.bashrc and adding the following line:

```
export PYTHONPATH=\$PYTHONPATH:/home/.../hsdk-python/src
```

Most of the Python scripts operate on boards connected on a serial bus and superuser privileges must be employed to access the ports. After running a command prefixed with sudo, the environment paths become those of root, so the locally set PYTHONPATH is not visible anymore. That is why /etc/sudoers is modified to keep the environment variable when changing user.

Edit /etc/sudoers with your favorite text editor. Modify:

```
Defaults env_reset -> Defaults env_keep="PYTHONPATH"
```

As an alternative to avoid modifying the :sudoers file, the PYTHONPATH can be adjusted programmatically, as in the example below:

```
import sys

if sys.platform.startswith('linux'):
    sys.path.append('/home/user/hsdk-python/src')
```

Windows OS

Add the source folder to the PYTHONPATH by following these steps:

1. Navigate to My Computer > Properties > Advanced System Settings > Environment Variables > System Variables.
2. Modify existing or create new variable named PYTHONPATH, with the absolute path of tools\wireless\host_sdk\hsdk-python\src.

Directory Tree

```

Functional description

The interaction between Python and the C libraries is made by the ctypes module. Ctypes provides C compatible data types, and allows calling functions in DLLs or shared libraries. It can be used to wrap these libraries in pure Python. Because the use of shared libraries is a requirement, the LIB_OPTION variable must remain set on “dynamic” in hsdk/Makefile. Ctypes made into mainline Python starting with version 2.5.

The Python Bindings expose Bluetooth LE familiar API in the `com.nxp.wireless_connectivity.commands` package. Such a package contains the following modules:

```
bluetooth le
   enums.py          – Classes that resemble enums, constants are generated here.
   events.py         – Observer classes that can build an object from a byte array and deliver it to the user.
   frames.py         – Classes that map on Bluetooth LE/Firmware FSCI messages.
   operations.py     – Each Operation class encapsulates a request and one or multiple events that are to be␣
↪generated by the request.
   spec.py           – This file describes the name, size, order and relationship between the command␣
↪parameters.
   sync_requests.py  – Each Synchronous Request is a method which sends a request and returns the␣
↪triggered event.
```

Tests and examples are placed in the package com.nxp.wireless_connectivity.test.

Bluetooth LE Heart Rate Service use case

The Heart Rate Service is presented as use case for using the API of a Bluetooth LE *black box*, located in the example hsdk-python/src/com/nxp/wireless_connectivity/test/hrs.py.

The example populates the GATT Database dynamically with the GATT, GAP, heart rate, battery and device information services. It then configures the Bluetooth LE stack and starts advertising. There are also two connect and disconnect observers to handle specific events.

The user needs to connect to the Bluetooth LE or hybrid *black box* through a serial bus port that is passed as a command line argument, for example, /dev/ttyACM0.

```
# python hrs.py -h
usage: hrs.py [-h] [-p] serial_port

Bluetooth LE demo app which implements a ble_fsci_heart_rate_sensor.

positional arguments:
   serial_port Kinetis-W system device node.
optional arguments:
   -h, --help  show this help message and exit
   -p, --pair  Use pairing
```

It is important to first execute a CPU reset request to the Bluetooth LE *black box* before performing any other configuration to reset the Buetooth LE stack. This is done by the following command:

```
FSCICPUReset(serial_port, protocol=Protocol.BLE)
```

User sync request example

It is recommended for the user to access the Bluetooth LE API through sync requests. GATTDBDynamicAddCharacteristicDeclarationAndValue API is used as an example:

```
def gattdb_dynamic_add_cdv(self, char_uuid, char_prop, maxval_len, initval, val_perm):
   '''
   Declare a characteristic and assign it a value.

   @param char_uuid: UUID of the characteristic
   @param char_prop: properties of the characteristic
   @param maxval_len: maximum length of the value
   @param initval: initial value
   @param val_perm: access permissions on the value
   @return: handle of the characteristic
   '''
   ind = GATTDBDynamicAddCharacteristicDeclarationAndValue(
      self.serial_port,
      UuidType=UuidType.Uuid16Bits,
      Uuid=char_uuid,
```

(continues on next page)

(continued from previous page)

```
        CharacteristicProperties=char_prop,
        MaxValueLength=maxval_len,
        InitialValueLength=len(initval),
        InitialValue=initval,
        ValueAccessPermissions=val_perm,
        protocol=self.protocol
    )
    if ind is None:
        return self.gattdb_dynamic_add_cdv(char_uuid, char_prop, maxval_len, initval, val_perm)

    print '\tCharacteristic Handle for UUID 0x%04X ->' % char_uuid, ind.CharacteristicHandle
    self.handles[char_uuid] = ind.CharacteristicHandle
    return ind.CharacteristicHandle
```

Sync request internal implementation

As an example, for the GATTDBDynamicAddCharacteristicDeclarationAndValue API, the command is executed through a synchronous request. The sync request code creates an object of the following class:

```
class GATTDBDynamicAddCharacteristicDeclarationAndValueRequest(object):

    def __init__(self,
UuidType=GATTDBDynamicAddCharacteristicDeclarationAndValueRequestUuidType.Uuid16Bits, Uuid=[],
CharacteristicProperties=GATTDBDynamicAddCharacteristicDeclarationAndValueRequestCharacteristicProperties.
↪gNone_c,
MaxValueLength=bytearray(2), InitialValueLength=bytearray(2), InitialValue=[],
ValueAccessPermissions=GATTDBDynamicAddCharacteristicDeclarationAndValueRequestValueAccessPermissions.
↪gPermissionNone_c):
    '''
    @param UuidType: UUID type
    @param Uuid: UUID value
    @param CharacteristicProperties: Characteristic properties
    @param MaxValueLength: If the Characteristic Value length is variable, this is the maximum length; for␣
↪fixed lengths this must be set to 0
    @param InitialValueLength: Value length at initialization; remains fixed if maxValueLength is set to 0,␣
↪otherwise cannot be greater than maxValueLength
    @param InitialValue: Contains the initial value of the Characteristic
    @param ValueAccessPermissions: Access permissions for the value attribute
    '''
    self.UuidType = UuidType
    self.Uuid = Uuid
    self.CharacteristicProperties = CharacteristicProperties
    self.MaxValueLength = MaxValueLength
    self.InitialValueLength = InitialValueLength
    self.InitialValue = InitialValue
    self.ValueAccessPermissions = ValueAccessPermissions
```

An operation is represented by an object of the following class:

```
class GATTDBDynamicAddCharacteristicDescriptorOperation(FsciOperation):

    def subscribeToEvents(self):
        self.spec = Spec.GATTDBDynamicAddCharacteristicDescriptorRequestFrame
        self.observers =[GATTDBDynamicAddCharacteristicDescriptorIndicationObserver(
↪'GATTDBDynamicAddCharacteristicDescriptorIndication'), ]
        super(GATTDBDynamicAddCharacteristicDescriptorOperation, self).subscribeToEvents()
```

The Spec object is initialized and set to zero in the FSCI packet any parameter not passed through the object of a class, depending on its length. Also, when defining such an object, the parameters may take simple integer, boolean or even list values instead of byte arrays, the values are serialized as a byte stream.

The observer is an object of the following class:

```
class GATTDBDynamicAddCharacteristicDeclarationAndValueIndicationObserver(Observer):
    opGroup = Spec.GATTDBDynamicAddCharacteristicDeclarationAndValueIndicationFrame.opGroup
    opCode = Spec.GATTDBDynamicAddCharacteristicDeclarationAndValueIndicationFrame.opCode

    @overrides(Observer)
    def observeEvent(self, framer, event, callback, sync_request):
    # Call super, print common information
    Observer.observeEvent(self, framer, event, callback, sync_request)
    #Get payload
    fsciFrame = cast(event, POINTER(FsciFrame))
    data = cast(fsciFrame.contents.data, POINTER(fsciFrame.contents.length * c_uint8))
    packet = Spec.GATTDBDynamicAddCharacteristicDeclarationAndValueIndicationFrame.
↪getFsciPacketFromByteArray(data.contents, fsciFrame.contents.length)
    # Create frame object
    frame = GATTDBDynamicAddCharacteristicDeclarationAndValueIndication()
    frame.CharacteristicHandle = packet.getParamValueAsNumber("CharacteristicHandle")
    framer.event_queue.put(frame) if sync_request else None

    if callback is not None:
        callback(frame)
    else:
        print_event(self.deviceName, frame)
    fsciLibrary.DestroyFSCIFrame(event)
```

The status of the request is printed at the console by the following general status handler:

```
def subscribe_to_async_ble_events_from(device, ack_policy=FsciAckPolicy.GLOBAL):
    ble_events = [
        L2CAPConfirmObserver('L2CAPConfirm'),
        GAPConfirmObserver('GAPConfirm'),
        GATTConfirmObserver('GATTConfirm'),
        GATTDBConfirmObserver('GATTDBConfirm'),
        GAPGenericEventInitializationCompleteIndicationObserver(
↪'GAPGenericEventInitializationCompleteIndication'),
        GAPAdvertisingEventCommandFailedIndicationObserver(
↪'GAPAdvertisingEventCommandFailedIndication'),
        GATTServerErrorIndicationObserver('GATTServerErrorIndication'),
        GATTServerCharacteristicCccdWrittenIndicationObserver(
↪'GATTServerCharacteristicCccdWrittenIndication')
    ]

    for ble_event in ble_events:
        FsciFramer(device, FsciAckPolicy.GLOBAL, Protocol.BLE, Baudrate.BR115200).addObserver(ble_
↪event)
```

Connect and disconnect observers

The following code adds observers for the connect and disconnect events in the user class:

```
class BLEDevice(object):
    '''
    Class which defines the actions performed on a generic Bluetooth LE device.
    Services implemented: GATT, GAP, Device Info.
    '''
    self.framer.addObserver(
        GAPConnectionEventConnectedIndicationObserver('GAPConnectionEventConnectedIndication'),
        self.cb_gap_conn_event_connected_cb)
    self.framer.addObserver(GAPConnectionEventDisconnectedIndicationObserver(
↪'GAPConnectionEventDisconnectedIndication'),
    self.cb_gap_conn_event_disconnected_cb)
```

where the callbacks are:

```
def cb_gap_conn_event_connected_cb(self, event):
    '''
    Callback executed when a smartphone connects to this device.
    @param event: GAPConnectionEventConnectedIndication
    '''
    print_event(self.serial_port, event)
    self.client_device_id = event.DeviceId
    self.gap_event_connected.set()

def cb_gap_conn_event_disconnected_cb(self, event):
    '''
    Callback executed when a smartphone disconnects from this device.
    @param event: GAPConnectionEventdisConnectedIndication
    '''
    print_event(self.serial_port, event)
    self.gap_event_connected.clear()
```

From an Android™ or iOS-based smartphone, the user can use the Bluetooth LE Toolbox application in the Heart Rate profile. Random heart rate measurements in the range 60-100 are displayed every second, while battery values change every 10 seconds.

FSCI Messages XML

Overview

The Framework Serial Communication Interface (FSCI) module supports interfacing the BLE Host Stack with a host or a PC tool (Test Tool for Connectivity Products) using a serial communication line. If the FSCI is used with the NXP Test Tool for Connectivity products, the tool can use an XML file containing a detailed meta-description for serial commands and events. This XML file is provided in the software packages that include this document.

Bluetooth LE Host Stack interface set

The Bluetooth LE Host Stack layers that offer access using FSCI are L2CAP, L2CAP CB, GATT, GATTDB, GAP, FSCI, and NVM. Each layer provides primitives that an upper layer (profile/application) uses to access services of that layer. This document includes a detailed list of the provided primitives.

Basic requirements

Following are the hardware requirements for using FSCI API RM:

- IAR Embedded Workbench for Arm architecture
- NXP development boards (to be loaded with the **ble_fscibb** application)
- Optional Bluetooth LE sniffer for testing
- PC tool (Test Tool for Connectivity Products) or another host processor capable of communicating through UART, USB, SPI, or I2C

FSCI message description

This chapter describes the L2CAP, L2CAP CB, GATT, GATTDB, GAP, FSCI, and NVM commands (requests) and events (confirms and indications) in detail.

The BLE.xml document is found in the ble_fsci_app subfolder, and provides an XML representation of all these commands and events. The BLE_x.x.x.xml document is found in the ..\tools\wireless\xml_fsci\ subfolder, and provides an XML representation of all these commands and events.

How to interpret the XML

The XML is structured in <Commands> and <Events> tags, the contents grouped by layer. Each group contains the description <GroupDesc> and multiple <Cmd> tags (as shown below).

```
<BLE>
  <Commands>
    <L2CAP>
      <GroupDesc>L2CAP Commands</GroupDesc>
      <Cmd>
        <CmdName>L2CAP-Init.Request</CmdName>
        <CmdDesc>L2CAP initialization function</CmdDesc>
        <CmdHeader>41 01</CmdHeader>
        <CmdParms>
        </CmdParms>
      </Cmd>
    [...]
    </L2CAP>
    <L2CAPCB>
    [...]
    </L2CAPCB>
  [...]
  </Commands>
  <Events>
    [...]
  </Events>
  [...]
</BLE>
```

Every command or event is described in a <Cmd> that contains:

- the name - <CmdName>
- the description - <CmdDesc>
- the opGroup and opCode - <CmdHeader>
- the parameters - <CmdParms>

The parameters of a command/event are specified using the <Parm> tag and contain:

- the name - <ParmName>
- the description - <ParmDesc>
- the size - <ParmSize>
- the type - <ParmType>
- the last value - <ParmLastValue>
- the default value - <ParmDefaultValue>
- the type specifics - <ParmTypeSpecifics>

The type specifics tag is used where needed to specify certain behaviours:

- <ParmItem> for specifying *enum* items
- <ParmState> for specifying the state of a variable (e.g. *ReadOnly*)
- <ParmRange> for specifying the range of the values taken by a variable
- <Depend> for specifying a dependence on another variable (e.g.an *array*'s dependence on the length variable)
- <Parm> for specifying the parameters of a *struct*

FSCI message example

For example, the L2CAP-SendAttData.Request command has the following XML structure:

```
<Cmd>

Bluetooth Low Energy Connection Handover Introduction

Connection Handover is an NXP proprietary feature that enables a Bluetooth Low Energy connection to be seamlessly transferred from one device to another while the connected peer remains unaware.

This document explains how to integrate the NXP Bluetooth Low Energy Connection Handover feature in an application and provides detailed explanation of the most commonly used APIs and code examples.

Prerequisites

The Bluetooth Low Energy Connection Handover feature can be integrated in an application that fulfills the following requirements:

- Supported platforms: KW45, KW47 and KW43.
- Bluetooth Low Energy application that is using the lib_ble_OPT_host_cm33_iar.a host library.
- Communication channel between the Source and Target devices involved in the Connection Handover procedure.

Integration and APIs

Integration

All the APIs referenced in this section are available in the the full-featured libraries.

- *lib_ble_OPT_host_cm33_iar.a* (for IAR projects)
- *lib_ble_OPT_host_cm33_gcc.a* (for MCUX projects).

Parent topic:*Bluetooth LE Connection Handover Integration and APIs*

Connection Handover API availability

Gap_HandoverGetDataSize

```
bleResult_t Gap_HandoverGetDataSize(deviceId_t deviceId, uint32_t *pDataSize);
```

Description: Returns the size in octets of the Handover Data for the given peer device id.

Parameters:

- deviceId: Peer device identifier.
- pDataSize: Pointer to the size in octets of the Handover Data.

Returns: gBleSuccess_c or error.

Gap_HandoverGetData

```
bleResult_t Gap_HandoverGetData(deviceId_t deviceId, uint8_t *pData);
```

Description: Copies the data used by the Handover feature for the given peer device id.

Parameters:

- deviceId: Peer device identifier.
- pData: Pointer to memory location where the Handover data is to be copied.

Returns: gBleSuccess_c or error.

Gap_HandoverSetData

```
bleResult_t Gap_HandoverSetData(uint8_t *pData);
```

Description: Sets the data used by the Handover feature.

Parameters:

- pData: Pointer to memory location where the Handover data is found.

Returns: gBleSuccess_c or error.

Gap_HandoverSetLlPendingData

```
bleResult_t Gap_HandoverSetLlPendingData(uint16_t connectionHandle, uint8_t *pTxData);
```

Description: Sets the LL data pending on the target device to be transmitted after handover connect.

Parameters:

- connectionHandle: Handover connection identifier.
- pTxData: Pointer to memory location where the pending data is found.

Returns: gBleSuccess_c or error.

Gap_HandoverFreeData

```
bleResult_t Gap_HandoverFreeData(void);
```

Description: Frees reference to handover data provided through Gap_HandoverSetData().

Returns: gBleSuccess_c or gBleInvalidState_c if handover data reference is not set.

Gap_HandoverGetTime

```
bleResult_t Gap_HandoverGetTime(void);
```

Description: Gets timing information from Link Layer to be used in Handover process.

Returns: gBleSuccess_c or error.

Gap_HandoverSuspendTransmit

```
bleResult_t Gap_HandoverSuspendTransmit(deviceId_t deviceId, bleHandoverSuspendTransmitMode_t␣
↪mode, uint16_t eventCounter, uint8_t noOfConnIntervals);
```

Description: Suspends TX for the given connection.

Parameters:

- deviceId: Peer device identifier.
- mode: Mode.
- eventCounter: Event counter.
- noOfConnIntervals: Number of connection intervals during which TX is suspended. Use 0 for manual resume.

Returns: gBleSuccess_c or error.

Gap_HandoverResumeTransmit

```
bleResult_t Gap_HandoverResumeTransmit(deviceId_t deviceId);
```

Description: Resumes TX for the given connection.

Parameters:

- deviceId: Peer device identifier.

Returns: gBleSuccess_c or error.

Gap_HandoverAnchorNotification

```
bleResult_t Gap_HandoverAnchorNotification(deviceId_t deviceId, bleHandoverAnchorNotificationEnable_t␣
↪enable, uint8_t noOfReports);
```

Description: Enables or disables anchor notifications for the given peer.

Parameters:

- deviceId: Peer device identifier.
- enable: Enables or disables notifications.
- noOfReports: Number of reports to receive (0 for manual stop).

Returns: gBleSuccess_c or error.

Gap_HandoverAnchorSearchStart

```
bleResult_t Gap_HandoverAnchorSearchStart(gapHandoverAnchorSearchStartParams_t *pSearchParams);
```

Description: Starts anchor search with the given parameters.

Parameters:

- pSearchParams: Pointer to structure containing anchor search parameters. The structure contains:
  - startTime625: Slot of the anchor point timing of the connection event.
  - startTimeOffset: Slot offset of the anchor point timing of the connection event.
  - lastRxInstant: Last successful access address reception instant (unit 625 us).
  - accessAddress: Access address (4 bytes).
  - crcInit: CRC initialization value (3 bytes).
  - channelMap: Channel map (5 bytes, FF FF FF FF 1F if all channels are used).
  - connInterval: Connection interval (unit 1.25ms).
  - latency: Latency (unit connection interval).
  - supervisionTimeout: Supervision timeout (unit 10ms).
  - eventCounter: Current connection event counter.
  - centralSca: Sleep clock accuracy (0 to 7).
  - role: Role (0 for central and 1 for peripheral).
  - centralPhy: TX/RX PHY.
  - seqNum: Sequence number; bits 1-0: latest received SN and NESN; bits 5-4: latest transmitted SN and NESN.
  - hopAlgo2: Hop algorithm (0/1 for hop algorithm #1 or #2).
  - unmappedChannelIndex: Unmapped channel index (used only for hop algorithm #1).
  - hopIncrement: Hop increment.
  - ucNbReports: Number of connection intervals to monitor (0: continuous, 1-255: automatic stop).
  - uiEventCounterAdvance: Event counter delay to perform the search (0 to start ASAP).
  - timeout: Timeout in connection intervals (0 if no timeout).
  - timingDiffSlot: Slot difference of the LL timing.
  - timingDiffOffset: Slot offset difference of the LL timing.
  - mode: Search mode setting.

  - reportLatency: gHandoverAnchorMonitorEvent_c report latency. Applies only after a valid RSSI detection (0 = send all HCI events, use gHandoverAnchorMonitorReportLatencySendAll_c; 1-254 = skip that many events with valid RSSI; 255 = drop all HCI events with valid RSSI, use gHandoverAnchorMonitorReportLatencyDropAll_c).
  - connEvtRxLatency: Connection events RX operation latency. Applies only after a valid RSSI detection (0 = monitor all connection events for the radio RX; 1-255 = skip that many connection events during the radio RX).

Returns: gBleSuccess_c or error.

Gap_HandoverAnchorSearchStop

```
bleResult_t Gap_HandoverAnchorSearchStop(uint16_t connHandle);
```

Description: Stops anchor search for the given connection handle.

Parameters:

- connHandle: Connection handle for which to stop the anchor search.

Returns: gBleSuccess_c or error.

Gap_HandoverTimeSyncTransmit

```
bleResult_t Gap_HandoverTimeSyncTransmit(gapHandoverTimeSyncTransmitParams_t *pTransmitParams);
```

Description: Starts time sync advertising with given parameters.

Parameters:

- pTransmitParams: Pointer to structure containing time sync transmit parameters. The structure contains:
  - enable: Enables or disables the transmit operation (0 = disable, 1 = enable).
  - advChannel: BLE channel to use for advertising (0 to 39).
  - deviceAddress: Packet identifier, can be the BD address or any value (6 bytes).
  - phys: PHY setting (0 = 1M, 1 = 2M, 2 = LR S8, 3 = LR S2).
  - txPowerLevel: TX Power level (0 to 31).
  - txIntervalSlots625: Packet interval in slots (4 to 255).

Returns: gBleSuccess_c or error.

Gap_HandoverTimeSyncReceive

```
bleResult_t Gap_HandoverTimeSyncReceive(gapHandoverTimeSyncReceiveParams_t *pReceiveParams);
```

Description: Starts time sync scanning with the given parameters.

Parameters:

- pReceiveParams: Pointer to structure containing time sync receive parameters. The structure contains:
  - enable: Enables or disables the receive operation (0 = disable, 1 = enable).
  - scanChannel: BLE channel to use for scanning (0 to 39).
  - deviceAddress: Packet identifier, can be the BD address or any value (6 bytes).
  - phys: PHY setting (0 = 1M, 1 = 2M, 2 = LR S8, 3 = LR S2).
  - stopWhenFound: One-shot setting (0 = continue scanning, 1 = stop when packet is found).

Returns: gBleSuccess_c or error.

Gap_HandoverGetConnParams

```
bleResult_t Gap_HandoverGetConnParams(uint16_t connHandle, gapConnectionCallback_t
↪connectionCallback, uint8_t anchorNotification);
```

Description: Connects to a peer device initialized through the Connection Handover procedure.

Parameters:

- connHandle: Handover Connection handle.
- connectionCallback: Pointer to the connection event handler function.
- anchorNotification: Anchor search setting after handover, 0 - stop anchor notification, 1 - keep anchor notification.

Returns: gBleSuccess_c or error.

Gap_HandoverDisconnect

```
bleResult_t Gap_HandoverDisconnect(deviceId_t deviceId);
```

Description: Disconnects a peer device for which the connection was handed over to another device.

Parameters:

- deviceId: Peer device identifier.

Returns: gBleSuccess_c or error.

Gap_HandoverInit

```
bleResult_t Gap_HandoverInit(void);
```

Description: Initializes the connection handover feature. Must be called before Ble_Initialize().

Returns: gBleInvalidState_c if Ble_Initialize() was already called, gBleSuccess_c otherwise.

Gap_HandoverSetSkd

```
bleResult_t Gap_HandoverSetSkd(uint8_t nvmIndex, uint8_t *pSkd);
```

Description: Sets the SKD of the connection that is to be handed over. Used only if gAppSecureMode_d is enabled in the application. Requires Handover Data to be set.

Parameters:

- nvmIndex: Bonding Data NVM index.
- pSkd: Pointer to 16 octets SKD.

Returns: gBleInvalidState_c if Ble_Initialize() was already called, gBleSuccess_c otherwise.

Gap_HandoverGetCsLlContext

```
bleResult_t Gap_HandoverGetCsLlContext(deviceId_t deviceId);
```

Description: Copies the LL CS-related context data for the given peer device id.

Parameters:

- deviceId: Peer device identifier.

Returns: gBleSuccess_c or error.

Gap_HandoverSetCsLlContext

```
bleResult_t Gap_HandoverSetCsLlContext(deviceId_t deviceId, uint16_t mask, uint8_t contextLength,␣
↪uint8_t *pContextData);
```

Description: Sets the CS-related context data into the LL, for the given peer device id.

Parameters:

- deviceId: Peer device identifier.
- mask: Context data bitmask (used by the LL).
- contextLength: Length of the context data.
- pContextData: Pointer to context data.

Returns: gBleSuccess_c or error.

Gap_HandoverUpdateConnParams

```
bleResult_t Gap_HandoverUpdateConnParams(gapHandoverUpdateConnParams_t *pConnParams);
```

Description: Updates the channel map and/or PHY used in the current anchor monitoring process.

Parameters:

- pConnParams: Pointer to connection parameters to be updated.

Returns: gBleSuccess_c or error.

Gap_HandoverApplyConnectionUpdateProcedure

```
bleResult_t Gap_
↪HandoverApplyConnectionUpdateProcedure(gapHandoverApplyConnectionUpdateProcedure_t␣
↪*pConnParams);
```

Description: Applies the new connection parameters in case of Connection Update Procedure on the active controller.

Parameters:

- pConnParams: Pointer to connection parameters to be applied.

Returns: gBleSuccess_c or error.

Connection Handover Events

The following events can be received through the GAP generic callback during the handover operations:

gHandoverGetComplete_c (0x31)

Description: Event generated when handover data get operation is complete.

Event Data: handoverGetData_t containing:

- status: Command status.
- pData: Pointer to connection handover data.

gHandoverSetComplete_c (0x32)

Description: Event generated when handover data set operation is complete.

Event Data: handoverSetData_t containing:

- status: Command status.
- pData: Pointer to connection handover data.

gHandoverGetCsLlContextComplete_c (0x33)

Description: Event generated when handover CS LL context data get operation is complete.

Event Data: handoverGetCsLlContext_t containing:

- status: Command status.
- responseMask: LL context bitmap indicating the Channel Sounding context.
- llContextLength: Context data length.
- llContext: LL Context data.

gHandoverSetCsLlContextComplete_c (0x34)

Description: Event generated when handover CS LL context data set operation is complete.

Event Data: Status of the operation.

gHandoverGetTime_c (0x35)

Description: Event generated when Handover Get Time command is complete.

Event Data: handoverGetTime_t containing:

- status: Command status.
- slot: LL timing slot counter (unit 625us).
- us_offset: LL timing slot offset (0 to 624, unit us).

gHandoverSuspendTransmitComplete_c (0x36)

Description: Event generated when Handover Suspend Transmit command is complete.

Event Data: handoverSuspendTransmitCompleteEvent_t containing:

- connectionHandle: Connection identifier.
- noOfPendingAclPackets: Number of pending ACL packets.
- sizeOfPendingAclPackets: Pending ACL packet data size.
- sizeOfDataTxInOldestPacket: Size of data transmitted and acked in the oldest ACL packet.
- sizeOfDataNAckInOldestPacket: Size of data transmitted but not acked in the oldest ACL packet.

gHandoverResumeTransmitComplete_c (0x37)

Description: Event generated when Handover Resume Transmit command is complete.

Event Data: handoverResumeTransmitCompleteEvent_t containing:

- connectionHandle: Connection identifier.

gHandoverAnchorNotificationStateChanged_c (0x38)

Description: Event generated when Handover Anchor Notification command is complete.

Event Data: handoverAnchorNotificationStateChanged_t containing:

- connectionHandle: Connection identifier.

gHandoverAnchorSearchStarted_c (0x39)

Description: Event generated when Handover Anchor Search Start command is complete.

Event Data: handoverAnchorSearchStart_t containing:

- status: Command status.
- connectionHandle: Connection identifier.

gHandoverAnchorSearchStopped_c (0x3A)

Description: Event generated when Handover Anchor Search Stop command is complete.

Event Data: handoverAnchorSearchStop_t containing:

- status: Command status.
- connectionHandle: Connection identifier.

gHandoverTimeSyncTransmitStateChanged_c (0x3B)

Description: Event generated when Handover Time Sync Transmit command is complete.

Event Data: Status of the operation.

gHandoverTimeSyncReceiveComplete_c (0x3C)

Description: Event generated when Handover Time Sync Receive command is complete.

Event Data: Status of the operation.

gHandoverAnchorMonitorEvent_c (0x3D)

Description: Event received from Controller - Handover Anchor Monitor.

Event Data: handoverAnchorMonitorEvent_t containing:

- connectionHandle: Connection identifier.
- connEvent: Current connection event counter.
- rssiRemote: RSSI of the packet from the remote device (+127 if not available).
- lqiRemote: LQI (Link Quality Indicator) of the packet from the remote device.
- statusRemote: Status of the packet from the remote device.
- rssiActive: RSSI of the packet from the active device (+127 if not available).
- lqiActive: LQI (Link Quality Indicator) of the packet from the active device.
- statusActive: Status of the packet from the active device.
- anchorClock625Us: Slot of the anchor point timing of the connection event.
- anchorDelay: Slot offset of the anchor point timing of the connection event.
- chIdx: BLE channel index.
- ucNbReports: Number of remaining reports to receive.

gHandoverTimeSyncEvent_c (0x3E)

Description: Event received from Controller - Handover Time Sync.

Event Data: handoverTimeSyncEvent_t containing:

- txClkSlot: Transmitter packet start time in slot (625 us).
- txUs: Transmitter packet start time offset inside the slot (0 to 624 us).
- rxClkSlot: Receiver packet start time in slot (625 us).
- rxUs: Receiver packet start time offset inside the slot (0 to 624 us).
- rssi: RSSI value.

gHandoverConnParamUpdateEvent_c (0x3F)

Description: Event received from Controller - Handover Connection Parameters Update.

Event Data: handoverConnParamUpdateEvent_t containing:

- status: Status indicating the event trigger source.
- connectionHandle: Connection identifier.
- ulTxAccCode: Access address.
- aCrcInitVal: CRC initialization value (3 bytes).
- uiConnInterval: Connection interval (unit 1.25ms).
- uiSuperTO: Supervision timeout (unit 10ms).
- uiConnLatency: Latency (unit connection interval).
- aChMapBm: Channel map (5 bytes).
- ucChannelSelection: Hop algorithm (0/1 for algorithm #1 or #2).
- ucHop: Hop increment.
- ucUnMapChIdx: Unmapped channel index.
- ucCentralSca: Sleep clock accuracy.
- ucRole: Role (0 for central and 1 for peripheral).
- aucRemoteMasRxPHY: TX/RX PHY.
- seqNum: Sequence number.
- uiConnEvent: Current connection event counter.
- ulAnchorClk: Slot of the anchor point timing.
- uiAnchorDelay: Slot offset of the anchor point timing.
- ulRxInstant: Last successful access address reception instant.

gHandoverFreeComplete_c (0x46)

Description: Event generated when handover data free operation is complete.

Event Data: Status of the operation.

gHandoverUpdateConnParamsComplete_c (0x47)

Description: Event generated when Handover Update Connection Parameters command is complete.

Event Data: handoverUpdateConnParams_t containing:

- status: Command status.
- connectionHandle: Connection identifier.

gHandoverLlPendingData_c (0x4A)

Description: Event indicating ACL Data pending to be transmitted by the LL.

Event Data: handoverLlPendingDataIndication_t containing:

- dataSize: Pending HCI ACL data packet size.
- pData: Pointer to message containing the HCI ACL data packet (should be freed by the application).

gHandoverAnchorMonitorPacketEvent_c (0x44)

Description: Event received from Controller - Handover Anchor Monitor Packet.

Event Data: handoverAnchorMonitorPacketEvent_t containing:

- packetCounter: Packet counter, incremented for each event.
- connectionHandle: Connection identifier.
- statusPacket: Status of the packet.
  - b0: CRC status - valid (1) or invalid (0).
  - b1: packet transmitter - central (1) or peripheral (0).
- phy: PHY (0/1/2/3 for 1M/2M/LR S8/LR S2).
- chIdx: BLE channel index.
- rssiPacket: RSSI of the packet (+127 if not available).
- lqiPacket: LQI (Link Quality Indicator) of the packet.
- connEvent: Current connection event counter.
- anchorClock625Us: Slot value of packet start time (in 625us unit).
- anchorDelay: Slot offset value of packet start time (in 1us unit).
- ucNbConnIntervals: Number of remaining connection intervals to monitor.
- pduSize: PDU length.
- pPdu: Pointer to PDU data (must be freed by the application).

gHandoverAnchorMonitorPacketContinueEvent_c (0x45)

Description: Event received from Controller - Handover Anchor Monitor Packet Continue.

Event Data: handoverAnchorMonitorPacketContinueEvent_t containing:

- packetCounter: Packet counter, incremented for each event.
- connectionHandle: Connection identifier.
- pduSize: PDU length.
- pPdu: Pointer to PDU data (must be freed by the application).

gHandoverConnectionUpdateProcedureEvent_c (0x4F)

Description: Event reporting new connection parameters indicated during the Connection Update procedure.

Event Data: handoverConnectionUpdateProcedureEvent_t containing:

- connectionHandle: Connection identifier.
- winSize: Transmit window size value (in 1.25 ms units).
- winOffset: Transmit window offset value (in 1.25 ms units).
- interval: Connection interval value (in 1.25 ms units).
- latency: Connection peripheral latency value.
- timeout: Connection supervision timeout value (in 10 ms units).
- instant: Connection event counter value when new parameters will be applied.
- currentEventCounter: Current connection event counter.

gHandoverApplyConnectionUpdateProcedureComplete_c (0x50)

Description: Event reporting completion of the Connection Update procedure application.

Event Data: handoverApplyConnectionUpdateProcedure_t containing:

- connectionHandle: Connection identifier.

Application common modules

The following application common modules are meant to offer a simplified API for generic Connection Handover procedures and allow for quick integration into existing applications.

Handover application common module

Introduction

The Connection Handover application common module allows for quick integration of the Connection Handover feature in a Bluetooth LE application.

Integration

All the APIs referenced in this section are available in the Connection Handover application common module.

Connection handover requires a communication interface with the other devices involved in the connection handover process.

Perform the following steps to integrate Connection Handover in an application:

1. Add app_handover.c and app_handover.h from middleware\wireless\bluetooth\application\common\auto\ in the application project.
2. Initialize the Connection Handover application common module by calling AppHandover_Init().
3. Call AppHandover_ProcessA2ACommand() to handle connection handover commands received.
4. Call AppHandover_GenericCallback() in the application generic events callback to handle the following events:
   - gHandoverAnchorSearchStarted_c
   - gHandoverAnchorSearchStopped_c
   - gHandoverAnchorMonitorEvent_c
   - gHandoverSuspendTransmitComplete_c
   - gHandoverGetComplete_c
   - gGetConnParamsComplete_c

- gHandoverTimeSyncEvent_c
- gHandoverTimeSyncTransmitStateChanged_c
- gHandoverTimeSyncReceiveComplete_c
- gLlSkdReportEvent_c
- gInternalError_c
- gHandoverAnchorMonitorPacketEvent_c
- gHandoverAnchorMonitorPacketContinueEvent_c
- gHandoverFreeComplete_c
- gHandoverLlPendingData_c
- gHandoverConnectionUpdateProcedureEvent_c
- gHandoverApplyConnectionUpdateProcedureComplete_c

5. Call AppHandover_ConnectionCallback in the application connection events callback to handle the following events:
   - gConnEvtHandoverConnected_c
   - gHandoverDisconnected_c
6. To trigger connection handover:
   - **Standard flow** (Time Synchronization required): call AppHandover_SetPeerDevice() followed by AppHandover_StartTimeSync(TRUE).
   - **Fast flow** (Anchor/Packet Monitoring already active on Target): call AppHandover_StartConnectionHandover(deviceId). This skips Time Synchronization and Anchor Search entirely.

Connection Handover application common module APIs

AppHandover_Init

```
bleResult_t AppHandover_Init(appHandoverEventCb_t pfAppEventCb, gapConnectionCallback_t␣
↪pfConnectionCallback, appHandoverA2AInterfaceCb_t pfAppA2AInterfaceCb);
```

Description: Initializes the handover application common module.

Parameters:

- pfAppEventCb: Application callback for handover events.
- pfConnectionCallback: Connection callback for connection events.
- pfAppA2AInterfaceCb: Communication callback for handover data.

Returns: bleResult_t

AppHandover_TimeSyncTransmit

```
bleResult_t AppHandover_TimeSyncTransmit(bleHandoverTimeSyncEnable_t enable);
```

Description: Enables/disables transmission of time synchronization information.

Parameters:

- enable: Enables or disables the transmission of time synchronization parameters.

Returns: bleResult_t

AppHandover_TimeSyncReceive

```
bleResult_t AppHandover_TimeSyncReceive(bleHandoverTimeSyncEnable_t enable);
```

Description: Enables/disables reception of time synchronization information.

Parameters:

- enable: Enables or disables the reception of time synchronization parameters.

Returns: bleResult_t

AppHandover_StartTimeSync

```
void AppHandover_StartTimeSync(bool_t bTimeSyncForHandover);
```

Description: Triggers handover time synchronization.

Parameters:

- bTimeSyncForHandover: TRUE if handover is following, FALSE if RSSI sniffing is following.

Returns: None

AppHandover_TimeSyncTransmitSetParams

```
void AppHandover_TimeSyncTransmitSetParams(gapHandoverTimeSyncTransmitParams_t *pParams);
```

Description: Sets parameters for the transmission of time synchronization information.

Parameters:

- pParams: Tx params.

Returns: None

AppHandover_TimeSyncReceiveSetParams

```
void AppHandover_TimeSyncReceiveSetParams(gapHandoverTimeSyncReceiveParams_t *pParams);
```

Description: Sets parameters for the reception of time synchronization information.

Parameters:

- pParams: Rx params.

Returns: None

AppHandover_StartConnectionHandover

```
bleResult_t AppHandover_StartConnectionHandover(deviceId_t deviceId);
```

Description: Triggers connection handover without requiring time synchronization or anchor search. Anchor monitoring must already be in progress for the specified connection on the Target device.

Parameters:

- deviceId: Peer device identifier of the connection to be handed over.

Returns: bleResult_t

- gBleSuccess_c: Handover initiated successfully.
- gBleInvalidParameter_c: Invalid device identifier.
- gBleInvalidState_c: Handover already in progress.
- gBleUnavailable_c: Anchor monitoring not active for the specified connection.

AppHandover_SetPeerDevice

```
void AppHandover_SetPeerDevice(deviceId_t deviceId);
```

Description: Sets the peer device for connection handover.

Parameters:

- deviceId: Peer device identifier.

Returns: None

AppHandover_ProcessA2ACommand

```
void AppHandover_ProcessA2ACommand(uint8_t cmdId, uint32_t cmdLen, uint8_t *pCmdData);
```

Description: Processes handover commands.

Parameters:

- cmdId: Command identifier.
- cmdLen: Command length.
- pCmdData: Command data.

Returns: None

AppHandover_SetPeerSkd

```
bleResult_t AppHandover_SetPeerSkd(uint8_t *pSkd, uint8_t nvmIndex);
```

Description: Sets the peer LL SKD for connection handover with advanced secure mode.

Parameters:

- nvmIndex: Peer device NVM index.
- pSkd:

A2A application common module

Introduction

The A2A (Anchor-to-Anchor) application common module implements a sample communication interface between devices involved in the connection handover process.

Integration

Perform the following steps to integrate A2A application common module in an application:

1. Add app_a2a_interface.c and app_a2a_interface.h from middleware\wireless\bluetooth\application\common\auto\ in the application project.
2. Initialize the Connection Handover application common module by calling A2A_Init().
3. Use A2A_SendCommand() as the communication callback for the Connection Handover application common module.
4. Use A2A_SendSetBondingDataCommand() in the application to send the bonding data from the connected anchor to the target anchor after pairing a new device is successful.

A2A application common module APIs

A2A_Init

```
bleResult_t A2A_Init(serial_handle_t pSerialHandle, appA2ADataIndicationCb_t pfDataIndCb);
```

Description: Performs initialization of the Anchor to Anchor serial communication.

Parameters:

- pSerialHandle: Serial interface handle to be used for communication.
- pfConnectionCallback: Application callback for received packets.

Returns: bleResult_t

A2A_SendCommand

```
void A2A_SendCommand(uint8_t opGroup, uint8_t opCode, uint8_t *pPayload, uint16_t len);
```

Description: Send packet over the Anchor to Anchor interface.

Parameters:

- opGroup: Group identifier.
- opCode: Command identifier.
- pPayload: Pointer to command data.
- len: Command length.

Returns: None

A2B application common module

Introduction

The A2B (Alice to Bob) application common module takes advantage of the EdgeLock to EdgeLock Key Exchange feature of the EdgeLock Secure Enclave integrated in the KW45, KW47 and KW43 to derive a special internal key (E2E key) that may be used to import/export encrypted key material between two devices. This may be used to allow for secure transfer of the key material between the anchors involved in the Connection Handover process. The LTK and IRK included in the bonding data are transferred as encrypted blobs that may only be decrypted by the EdgeLock Secure Enclave of the destination device.

Integration

Perform the following steps to integrate A2B application common module in an application:

1. Add app_a2b.c and app_a2b.h from middleware\wireless\bluetooth\application\common\auto\ in the application project.
2. Initialize the A2B application common module by calling A2B_Init().
3. One of the device involved in the Connection Handover process must be configured with the gA2BInitiator_d macro set to 1, the other must be configured with the gA2BInitiator_d macro set to 0. The initiator device triggers the EdgeLock-to-EdgeLock (E2E) key derivation and local IRK synchronization. Therefore, it should be started last.
4. After initialization the E2E key will be derived and the gSecLibFunctions.pfSecLib_ExportA2BBlob() and gSecLibFunctions.pfSecLib_ImportA2BBlob() functions can be used to export and import encrypted key material between the two devices.

A2B application common module APIs

A2B_Init

```
bleResult_t A2B_Init(appA2BEventCb_t pfAppEventCb, appA2BA2ACommInterfaceCb_t␣
↪pfAppA2AInterfaceCb);
```

Description: Trigger the A2B feature initialization by generating the public key used for the Edgelock to Edgelock key derivation.

Parameters:

- pfAppEventCb: Application callback functions for A2B events.
- pfAppA2AInterfaceCb: Communication callback for A2B data.

Returns: bleResult_t - Result of the operation.

A2B_ProcessA2ACommand

```
void A2B_ProcessA2ACommand(uint8_t cmdId, uint32_t cmdLen, uint8_t *pCmdData);
```

Description: Process A2B commands received through the A2A interface.

Parameters:

- cmdId: Command identifier.
- cmdLen: Command length.
- pCmdData: Command data.

Returns: None

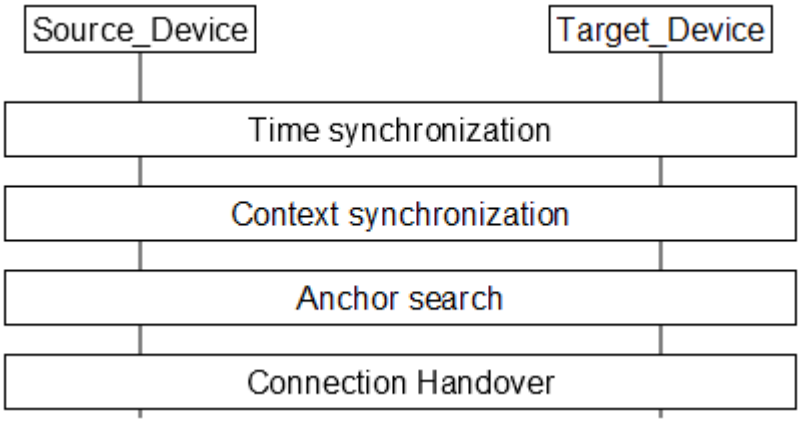
A2B_FreeE2EKey

```
bleResult_t A2B_FreeE2EKey(void);
```

Description: Free the EdgeLock to EdgeLock key.

Parameters: None

Returns: bleResult_t - Result of the operation.

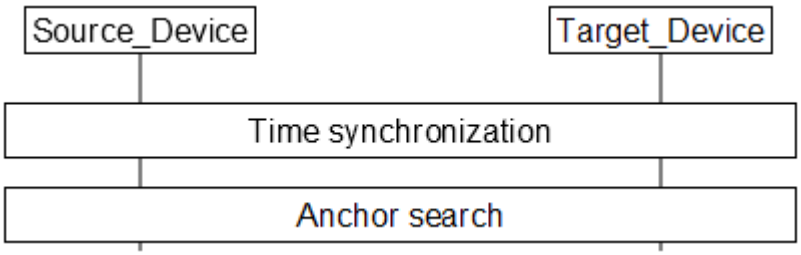


Procedures

This section describes the available Connection Handover procedures. A procedure is executed between a device in a connection, referred as the Source device, and another device involved in the Connection Handover or Anchor/Packet Monitoring process, referred to as the Target device.

Procedures - Top level view

The Connection Handover and Anchor/Packet Monitoring process comprises several procedures as illustrated below.



Connection Handover

Connection Handover (Monitoring Active)

When Anchor or Packet Monitoring is already active on the Target device, the Connection Handover can be performed directly without Time Synchronization or Anchor Search. The application triggers this flow by calling AppHandover_StartConnectionHandover(). The process skips directly to Context Synchronization and uses the existing monitoring state for the handover connect.

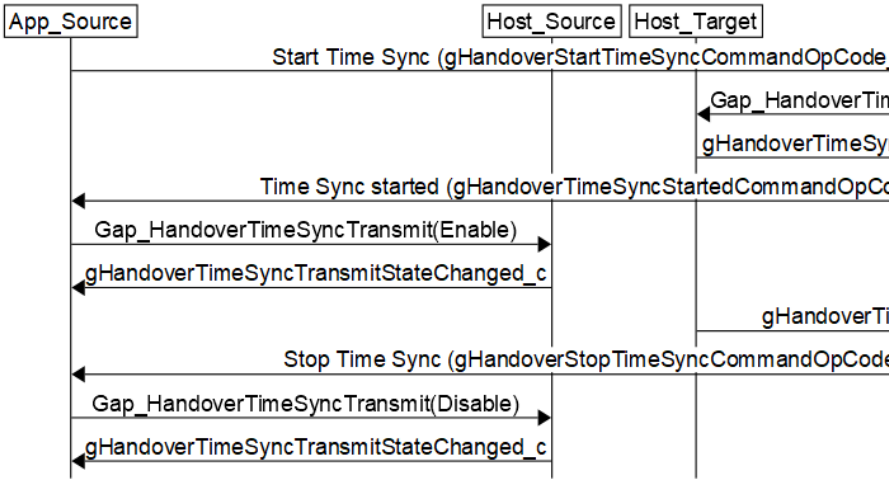
Anchor/Packet monitoring

Individual procedures

This section describes each individual procedure in detail.

Time synchronization

The Time Synchronization procedure enables precise timing alignment between the Source and Target devices for the Connection Handover and Anchor/Packet monitoring processes. The timing information obtained is further required for the Anchor Search procedure.



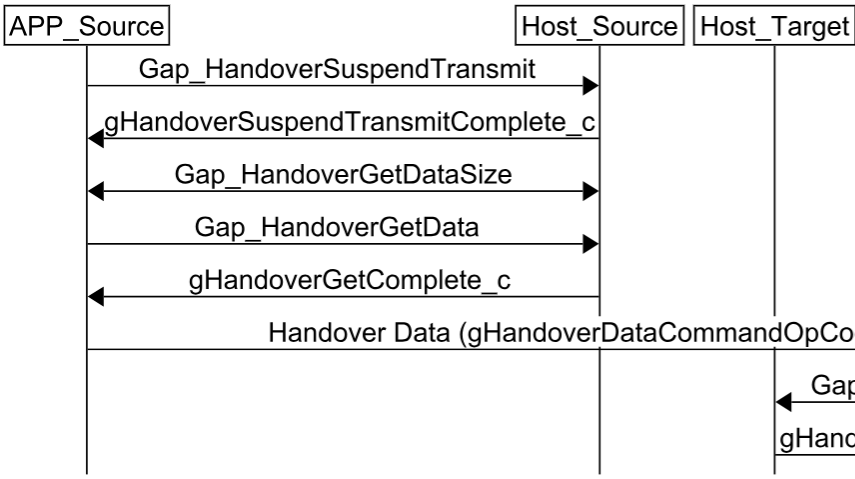
To start the time synchronization procedure, one of the devices must call GAP_HandoverTimeSyncReceive() and the other device must call GAP_HandoverTimeSyncTransmit(). Either device, Source or Target, can initiate the procedure. The Connection Handover application common module initiates the procedure on the Source device by notifying the Target device to call the Gap_HandoverTimeSyncReceive() function.

Time Synchronization steps

Time synchronization steps for two devices where the Target device starts the procedure:

1. Target device application calls GAP_HandoverTimeSyncReceive() with the stopWhenFound parameter set to 'gTimeSyncStopWhenFound_c'.
2. Target device receives the 'gHandoverTimeSyncReceiveComplete_c' event indicating that Source Link Layer is waiting for the time synchronization event.
3. Source device application calls GAP_HandoverTimeSyncTransmit()
4. Source device receives the 'gHandoverTimeSyncTransmitStateChanged_c' event indication that time synchronization transmission is enabled.

5. The Target device receives the 'gHandoverTimeSyncEvent_c' event containing the timing information.
6. The Target device computes the 'Gap_HandoverAnchorSearchStart' 'timingDiffSlot' and 'timingDiffOffset' parameters using the timing information received in the gHandoverTimeSyncEvent_c event as shown below: 'searchParams.timingDiffSlot = mSlotLocal - mSlotRemote' 'searchParams.timingDiffOffset = mOffsetLocal - mOffsetRemote;'



Time Synchronization signaling chart

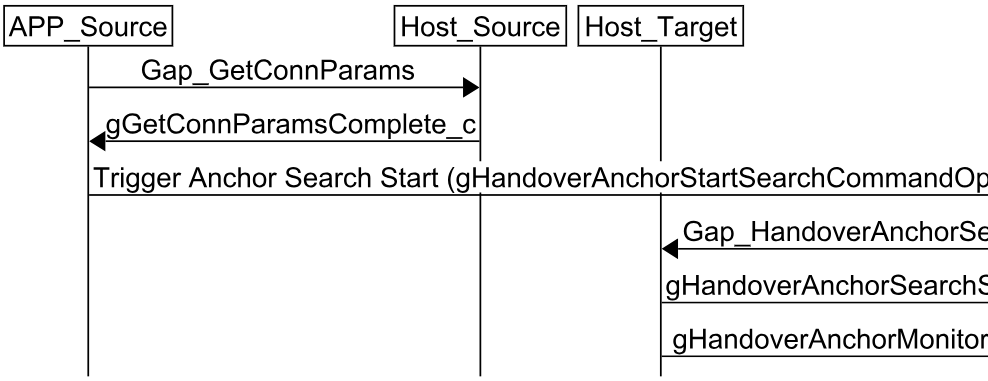
Context Synchronization

In order to transfer an existing connection from a Source device to a Target device, the Host and Link Layer connection context must be synchronized. The Handover Data includes all the required connection information, which must be retrieved from the Source device and transferred to the Target device. Potential issues include instances where the Host or Link Layer context is updated during the Connection Handover process. To avoid such issues, the Bluetooth LE communication between the Source device and the connected device must be suspended until the Connection Handover is complete or aborted. In case the Connection Handover process is aborted, the original connection can be resumed. This procedure is required only for the Connection Handover process and not for the Anchor/Packet Monitoring process.

Context Synchronization steps

1. Source device calls Gap_HandoverSuspendTransmit() to suspend the Bluetooth LE communication with the connected device.
2. After the gHandoverSuspendTransmitComplete_c event is received, the Handover Data may be retrieved using Gap_HandoverGetData(). The application must provided memory for the Handover Data. To obtain the required data size, use the function Gap_HandoverGetDataSize().
3. Wait for the gHandoverGetComplete_c event to confirm the Handover Data retrieval.
4. Transfer the Handover Data from the Source device to the Target device.
5. On the Target device, call Gap_HandoverSetData() to set the received Handover Data.
6. Wait for the gHandoverSetComplete_c event to confirm the Handover Data has been successfully set.

Context Synchronization signaling chart



Anchor Search

The Anchor Search procedure takes the connection parameters and timing information obtained in the Time Synchronization procedure to locate the anchor point of the connection between the source device and the connected device.

Anchor Search steps

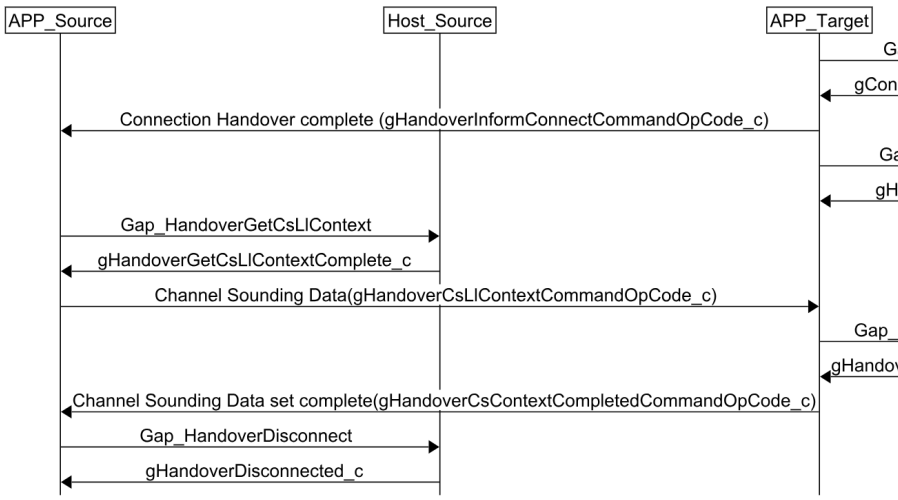
1. Source device calls Gap_GetConnParams() to retrieve current connection parameters. The connection parameters will be reported through the gGetConnParamsComplete_c event.
2. Send the connection parameters and the timing information obtained from Time Synchronization to the Target device.
3. On the Target device, call Gap_HandoverAnchorSearch() with the received connection parameters and timing information. Set the 'mode' parameter according to the current process:
   - 'gSuspendTxMode_c' for Connection Handover.
   - 'gRssiSniffingMode_c' for Anchor Monitoring.
   - 'gPacketMode_c' for Packet Monitoring.

   The Anchor Search parameters also include two settings that control the rate of the reported events. Both apply only after a valid RSSI detection:
   - 'reportLatency': controls the report rate of the gHandoverAnchorMonitorEvent_c events with valid RSSI. Set to 0 (gHandoverAnchorMonitorReportLatencySendAll_c) to send all HCI events; set to a value between 1 and 254 to skip that many events with valid RSSI; set to 255 (gHandoverAnchorMonitorReportLatencyDropAll_c) to drop all HCI events with valid RSSI.
   - 'connEvtRxLatency': controls the connection events RX operation latency. Set to 0 to monitor all the connection events for the radio RX; set to a value between 1 and 255 to skip that many connection events during the radio RX.
4. Wait for the gHandoverAnchorSearchStarted_c event to confirm the Anchor Search procedure has started.
5. If Anchor Search is successful the requested events will be reported to the application through the gHandoverAnchorMonitorEvent_c or gHandoverAnchorMonitorPacketEvent_c event.

Anchor Search signaling chart

Connection Handover

The Connection Handover procedure consists in the Target device taking over the connection from the Source device. It may be performed in two cases:

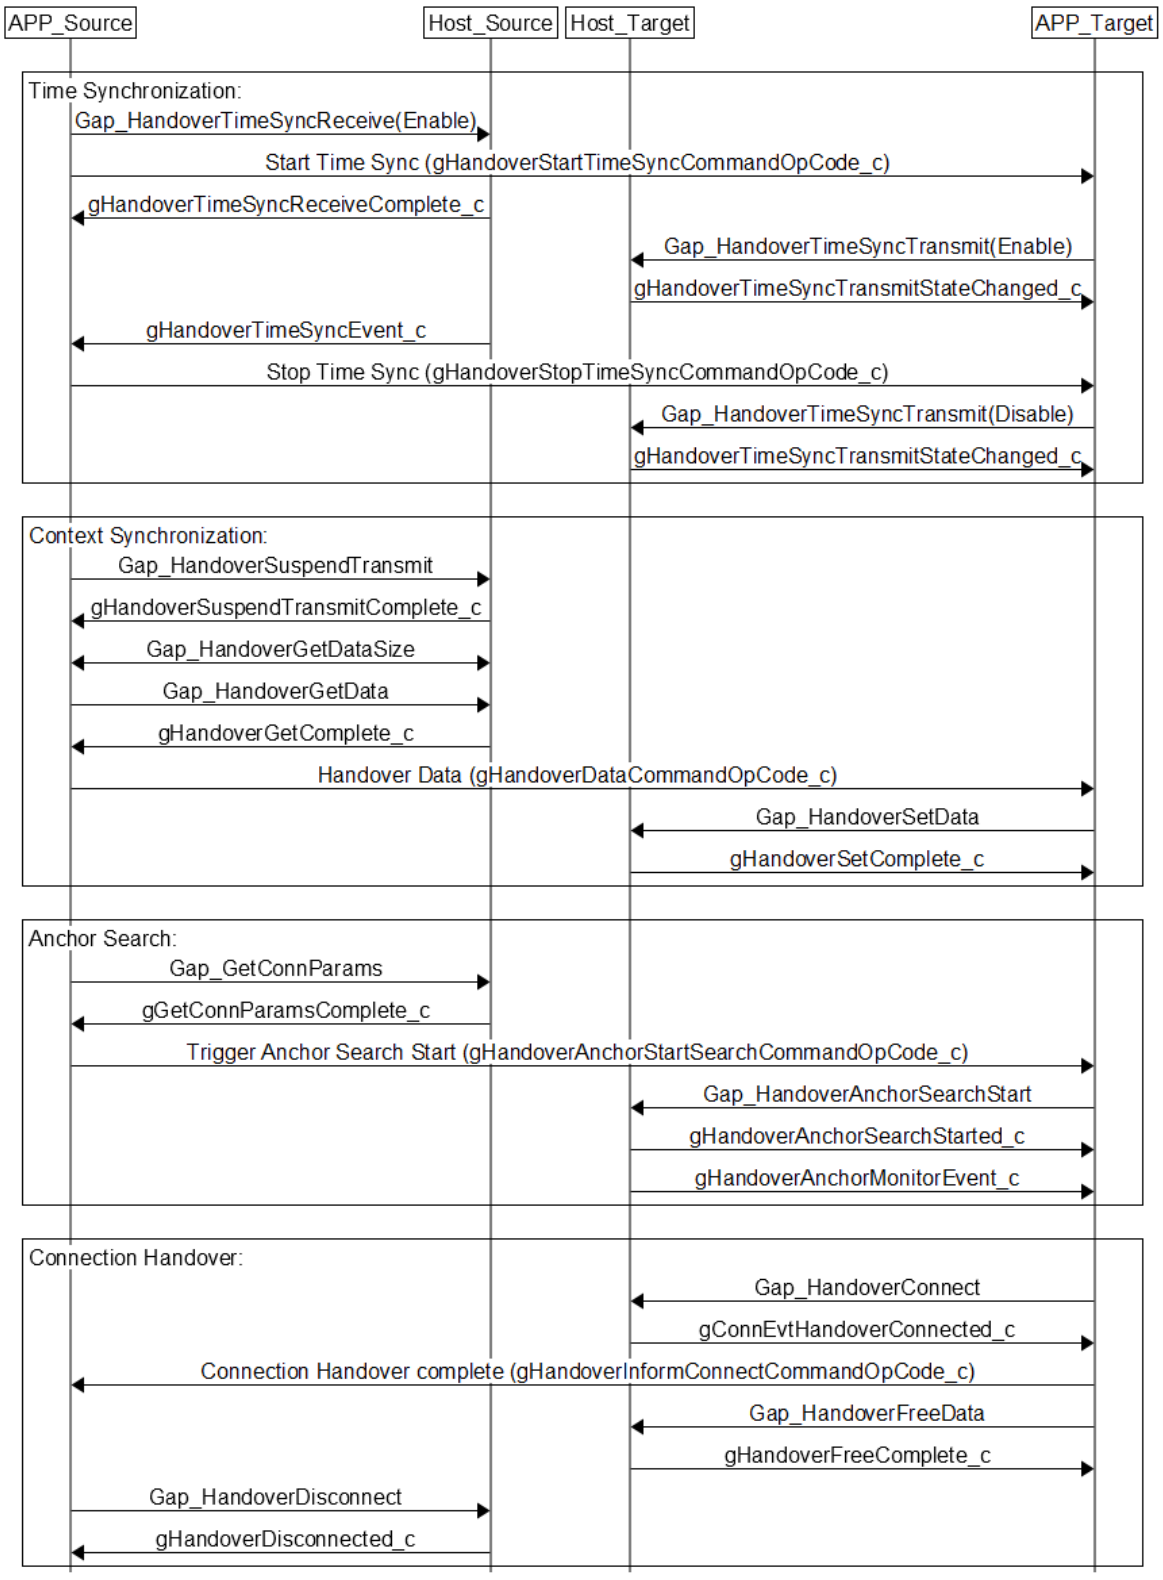


- After a successful Anchor Search procedure, as part of the standard handover flow.
- Directly without Time Synchronization or Anchor Search, when Anchor or Packet Monitoring is already active on the Target device.

Connection Handover steps

1. Target device calls Gap_HandoverConnect() to initiate the connection handover process.
2. Wait for the gConnEvtHandoverConnected_c event on the Target device. Once received, the connection has been successfully transferred.
3. Notify the Source device that the Target device has successfully connected to the Device.
4. If the application does not include Channel Sounding, call Gap_HandoverDisconnect on the Source device to terminate its connection.
5. The Handover Data is no longer required and may be freed by calling Gap_HandoverFreeData() on the Target device.
6. Application context may be transferred at this point through application specific means. If Channel Sounding is enabled in the application, the Channel Sounding Context must be transferred.

Additional steps for Channel Sounding applications:



1. After step 3 above, retrieve the Channel Sounding context on the Source device by calling Gap_HandoverGetCsLlContext() and wait for the gHandoverGetCsLlContextComplete event.
2. Send the Channel Sounding context to the Target device.
3. Set the context in the Target device by calling Gap_HandoverSetCsLlContext() and wait for the gHandoverSetCsLlContextComplete_c event.
4. Notify the Source device that the Channel Sounding context has been successfully set.
5. Call Gap_HandoverDisconnect() on the Source device to terminate its connection. When complete, the gHandoverDisconnected_c event will be sent.

Gap_HandoverDisconnect
gHandoverDisconnected_c

Connection Handover (Monitoring Active)

When Anchor or Packet Monitoring is already active on the Target device, the Connection Handover bypasses Time Synchronization and Anchor Search. The Source device suspends TX, retrieves and sends the Handover Data, and the Target device performs the handover connect on the next monitor event. See the Connection Handover section for the detailed step-by-step procedure and signaling chart.

Anchor/Packet Monitoring

Bluetooth Low Energy Host Stack API Reference Manual Groups

GAP

enum gapRole_t

GAP Role of a BLE device

Values:

enumerator gGapCentral_c

Central scans and connects to Peripherals.

enumerator gGapPeripheral_c

Peripheral advertises and connects to Centrals.

enumerator gGapObserver_c

Observer only scans and makes no connections.

enumerator gGapBroadcaster_c

Broadcaster only advertises and makes no connections.

enum gapKeypressNotification_tag

Values:

enumerator gKnPasskeyEntryStarted_c

Start of the Passkey Entry.

enumerator gKnPasskeyDigitStarted_c

Digit entered.

enumerator gKnPasskeyDigitErased_c

Digit erased.

enumerator gKnPasskeyCleared_c

Passkey cleared.

enumerator gKnPasskeyEntryCompleted_c

Passkey Entry completed.

enum gapScanMode_t

Scan Mode options; used as parameter for Gap_SetScanMode.

Values:

enumerator gDefaultScan_c

Reports all scanned devices to the application.

enumerator gLimitedDiscovery_c

Reports only devices in Limited Discoverable Mode, i.e., containing the Flags AD with the LE Limited Discoverable Flag set.

enumerator gGeneralDiscovery_c

Reports only devices in General Discoverable Mode, i.e., containing the Flags AD with the LE General Discoverable Flag set.

enumerator gAutoConnect_c

Automatically connects with devices with known addresses and does not report any scanned device to the application.

enum gapAdvertisingChannelMapFlags_t

Advertising Channel Map flags - setting a bit activates advertising on the respective channel.

Values:

enumerator gAdvChanMapFlag37_c

Bit for channel 37.

enumerator gAdvChanMapFlag38_c

Bit for channel 38.

enumerator gAdvChanMapFlag39_c

Bit for channel 39.

enum gapAdvertisingFilterPolicy_t

Advertising Filter Policy values

Values:

enumerator gProcessAll_c

Default value: accept all connect and scan requests.

enumerator gProcessConnAllScanWL_c

Accept all connect requests, but scan requests only from devices in Filter Accept List.

enumerator gProcessScanAllConnWL_c

Accept all scan requests, but connect requests only from devices in Filter Accept List.

enumerator gProcessFilterAcceptListOnly_c

Accept connect and scan requests only from devices in Filter Accept List.

enum gapPeriodicAdvSyncMode_tag

Periodic Advertisement Sync Transfer parameters

Values:

enumerator gapPeriodicSyncNoSyncMode_c

No attempt is made to synchronize to the periodic advertising and no gHciLePeriodicAdvSyncTransferReceived_c event is sent to the Host

enumerator gapPeriodicSyncNoReports_c

A gHciLePeriodicAdvSyncTransferReceived_c event is sent to the Host. gHciLePeriodicAdvReportEvent_c events will be disabled.

enumerator gapPeriodicSyncReportsEnabled_c

A gHciLePeriodicAdvSyncTransferReceived_c event is sent to the Host. gHciLePeriodicAdvReportEvent_c events will be enabled with duplicate filtering disabled

enumerator gapPeriodicSyncReportsEnabledWithDF_c

A gHciLePeriodicAdvSyncTransferReceived_c event is sent to the Host. gHciLePeriodicAdvReportEvent_c events will be enabled with duplicate filtering enabled

enum gapFilterDuplicates_t

Values:

enumerator gGapDuplicateFilteringDisable_c

Duplicate filtering disabled

enumerator gGapDuplicateFilteringEnable_c

Duplicate filtering enabled

enumerator gGapDuplicateFilteringPeriodicEnable_c

Duplicate filtering enabled, reset for each scan period

enum gapCreateSyncReqFilterPolicy_tag

Values:

enumerator gUseCommandParameters_c

Use the SID, peerAddressType, and peerAddress parameters to determine which advertiser to listen to.

enumerator gUsePeriodicAdvList_c

Use the Periodic Advertiser List to determine which advertiser to listen to

enum gapPrivateKeyType_t

Values:

enumerator gUseGeneratedKey_c

The private key generated by LE_Read_Local_P-256_Public_Key command, used for DH key generation

enumerator gUseDebugKey_c

The private debug key, used for DH key generation

enum gapAdType_t

AD Type values as defined by Bluetooth SIG used when defining *gapAdStructure_t* structures for advertising or scan response data.

Values:

enumerator gAdFlags_c

Defined by the Bluetooth SIG.

enumerator gAdIncomplete16bitServiceList_c

Defined by the Bluetooth SIG.

enumerator gAdComplete16bitServiceList_c

Defined by the Bluetooth SIG.

enumerator gAdIncomplete32bitServiceList_c

Defined by the Bluetooth SIG.

enumerator gAdComplete32bitServiceList_c

Defined by the Bluetooth SIG.

enumerator gAdIncomplete128bitServiceList_c

Defined by the Bluetooth SIG.

enumerator gAdComplete128bitServiceList_c
Defined by the Bluetooth SIG.

enumerator gAdShortenedLocalName_c
Defined by the Bluetooth SIG.

enumerator gAdCompleteLocalName_c
Defined by the Bluetooth SIG.

enumerator gAdTxPowerLevel_c
Defined by the Bluetooth SIG.

enumerator gAdClassOfDevice_c
Defined by the Bluetooth SIG.

enumerator gAdSimplePairingHashC192_c
Defined by the Bluetooth SIG.

enumerator gAdSimplePairingRandomizerR192_c
Defined by the Bluetooth SIG.

enumerator gAdSecurityManagerTkValue_c
Defined by the Bluetooth SIG.

enumerator gAdSecurityManagerOobFlags_c
Defined by the Bluetooth SIG.

enumerator gAdPeripheralConnectionIntervalRange_c
Defined by the Bluetooth SIG.

enumerator gAdServiceSolicitationList16bit_c
Defined by the Bluetooth SIG.

enumerator gAdServiceSolicitationList32bit_c
Defined by the Bluetooth SIG.

enumerator gAdServiceSolicitationList128bit_c
Defined by the Bluetooth SIG.

enumerator gAdServiceData16bit_c
Defined by the Bluetooth SIG.

enumerator gAdServiceData32bit_c
Defined by the Bluetooth SIG.

enumerator gAdServiceData128bit_c
Defined by the Bluetooth SIG.

enumerator gAdPublicTargetAddress_c
Defined by the Bluetooth SIG.

enumerator gAdRandomTargetAddress_c
Defined by the Bluetooth SIG.

enumerator gAdAppearance_c
Defined by the Bluetooth SIG.

enumerator gAdAdvertisingInterval_c
Defined by the Bluetooth SIG.

enumerator gAdLeDeviceAddress_c
Defined by the Bluetooth SIG.

enumerator gAdLeRole_c
Defined by the Bluetooth SIG.

enumerator gAdSimplePairingHashC256_c
Defined by the Bluetooth SIG.

enumerator gAdSimplePairingRandomizerR256_c
Defined by the Bluetooth SIG.

enumerator gAd3dInformationData_c
Defined by the Bluetooth SIG.

enumerator gAdUniformResourceIdentifier_c
Defined by the Bluetooth SIG.

enumerator gAdLeSupportedFeatures_c
Defined by the Bluetooth SIG.

enum gapDecisionInstructionsAdvAChecks_t

Values:

enumerator gDIAAC_AdvAinFilterAcceptList_c

enumerator gDIAAC_AdvAmatchAddress1_c

enumerator gDIAAC_AdvAmatchAddress1orAddress2_c

enum gapRadioPowerLevelReadType_t

Enumeration used by the Gap_ReadRadioPowerLevel function.

Values:

enumerator gTxPowerCurrentLevelInConnection_c

Reading the instantaneous TX power level in a connection.

enumerator gTxPowerMaximumLevelInConnection_c

Reading the maximum TX power level achieved during a connection.

enumerator gTxPowerLevelForAdvertising_c

Reading the TX power on the advertising channels.

enumerator gRssi_c

Reading the Received Signal Strength Indication in a connection.

enum gapControllerTestCmd_t

Enumeration for Controller Test commands.

Values:

enumerator gControllerTestCmdStartRx_c

Start Receiver Test.

enumerator gControllerTestCmdStartTx_c

Start Transmitter Test.

enumerator gControllerTestCmdEnd_c

End Test.

enum gapControllerTestTxType_tag

Values:

enumerator gControllerTestTxPrbs9_c

PRBS9 sequence ‘1111111100000111101’...

enumerator gControllerTestTxF0_c

Repeated ‘11110000’

enumerator gControllerTestTxAA_c

Repeated ‘10101010’

enumerator gControllerTestTxPrbs15_c

PRBS15 sequence

enumerator gControllerTestTxFF_c

Repeated ‘11111111’

enumerator gControllerTestTx00_c
Repeated '00000000'

enumerator gControllerTestTx0F_c
Repeated '00001111'

enumerator gControllerTestTx55_c
Repeated '01010101'

enum gapSleepClockAccuracy_t
Enumeration for Sleep Clock Accuracy command.

Values:

enumerator gSwitchToMoreAccurateClock_c

enumerator gSwitchToLessAccurateClock_c

enum gapAdvertisingEventType_t
Advertising event type enumeration, as contained in the *gapAdvertisingEvent_t*.

Values:

enumerator gAdvertisingStateChanged_c
Event received when advertising has been successfully enabled or disabled.

enumerator gAdvertisingCommandFailed_c
Event received when advertising could not be enabled or disabled. Reason contained in gapAdvertisingEvent_t.eventData.failReason.

enumerator gExtAdvertisingStateChanged_c
Event received when extended advertising has been successfully enabled or disabled.

enumerator gAdvertisingSetTerminated_c
Event received when advertising in a given advertising set has stopped.

enumerator gExtScanNotification_c
Event indicates that a SCAN_REQ PDU or an AUX_SCAN_REQ PDU has been received by the extended advertiser.

enumerator gPerAdvSubeventDataRequest_c
Event received when doing PAWR.

enumerator gPerAdvResponse_c
Periodic Advertising Response.

enum gapScanningEventType_t
Scanning event type enumeration, as contained in the *gapScanningEvent_t*.

Values:

enumerator gScanStateChanged_c

Event received when scanning had been successfully enabled or disabled, or a Scan duration time-out has occurred.

enumerator gScanCommandFailed_c

Event received when scanning could not be enabled or disabled. Reason contained in gapScanningEvent_t.eventData.failReason.

enumerator gDeviceScanned_c

Event received when an advertising device has been scanned. Device data contained in gapScanningEvent_t.eventData.scannedDevice.

enumerator gExtDeviceScanned_c

Event received when an advertising device has been scanned. Device data contained in gapScanningEvent_t.eventData.extScannedDevice.

enumerator gPeriodicDeviceScanned_c

Event received when an Periodic advertising device has been scanned. Device data contained in gapScanningEvent_t.eventData.periodicScannedDevice.

enumerator gPeriodicDeviceScannedV2_c

Event received when an Periodic advertising device has been scanned. Device data contained in gapScanningEvent_t.eventData.periodicScannedDeviceV2.

enumerator gPeriodicAdvSyncEstablished_c

Event received when a sync with a periodic advertiser was established.

enumerator gPeriodicAdvSyncLost_c

Event received when a sync with a periodic advertiser have been lost.

enumerator gPeriodicAdvSyncTerminated_c

Event received when a sync with a periodic advertiser have been terminated.

enumerator gConnectionlessIqReportReceived_c

Event received when the Controller has reported IQ information from the CTE of a received advertising packet

enumerator gMonAdvReportEventReceived_c

Event received when Monitored Advertisers is enabled

enum bleMonAdvCondition_t

Values:

enumerator gBleMonAdvConditionRssiLowThreshold_c

Monitored Advertisers RSSI value below the RSSI low threshold.

enumerator gBleMonAdvConditionRssiHighThreshold_c

Monitored Advertisers RSSI value greater than or equal to the RSSI high threshold.

enum gapConnectionEventType_t

Connection event type enumeration, as contained in the *gapConnectionEvent_t*.

Values:

enumerator gConnEvtConnected_c

A connection has been established. Data in gapConnectionEvent_t.eventData.connectedEvent.

enumerator gConnEvtPairingRequest_c

A pairing request has been received from the peer Central. Data in gapConnectionEvent_t.eventData.pairingEvent.

enumerator gConnEvtPeripheralSecurityRequest_c

A Peripheral Security Request has been received from the peer Peripheral. Data in gapConnectionEvent_t.eventData.peripheralSecurityRequestEvent.

enumerator gConnEvtPairingResponse_c

A pairing response has been received from the peer Peripheral. Data in gapConnectionEvent_t.eventData.pairingEvent.

enumerator gConnEvtAuthenticationRejected_c

A link encryption or pairing request has been rejected by the peer device. Data in gapConnectionEvent_t.eventData.authenticationRejectedEvent.

enumerator gConnEvtPasskeyRequest_c

Peer has requested a passkey (maximum 6 digit PIN) for the pairing procedure. Device should respond with Gap_EnterPasskey.

enumerator gConnEvtOobRequest_c

Out-of-Band data must be provided for the pairing procedure. Central or Peripheral should respond with Gap_ProvideOob.

enumerator gConnEvtPasskeyDisplay_c

The pairing procedure requires this Peripheral to display the passkey for the Central's user.

enumerator gConnEvtKeyExchangeRequest_c

The pairing procedure requires the SMP keys to be distributed to the peer. Data in gapConnectionEvent_t.eventData.keyExchangeRequestEvent.

enumerator gConnEvtKeysReceived_c

SMP keys distributed by the peer during pairing have been received. Data in gapConnectionEvent_t.eventData.keysReceivedEvent.

enumerator gConnEvtLongTermKeyRequest_c

The bonded peer Central has requested link encryption and the LTK must be provided. Peripheral should respond with Gap_ProvideLongTermKey. Data in gapConnectionEvent_t.eventData.longTermKeyRequestEvent.

enumerator gConnEvtEncryptionChanged_c

Link's encryption state has changed, e.g., during pairing or after a reconnection with a bonded peer. Data in gapConnectionEvent_t.eventData.encryptionChangedEvent.

enumerator gConnEvtPairingComplete_c

Pairing procedure is complete, either successfully or with failure. Data in gapConnectionEvent_t.eventData.pairingCompleteEvent.

enumerator gConnEvtDisconnected_c

A connection has been terminated. Data in gapConnectionEvent_t.eventData.disconnectedEvent.

enumerator gConnEvtRssiRead_c

RSSI for an active connection has been read. Data in gapConnectionEvent_t.eventData.rssi_dBm.

enumerator gConnEvtTxPowerLevelRead_c

TX power level for an active connection has been read. Data in gapConnectionEvent_t.eventData.txPowerLevel_dBm.

enumerator gConnEvtPowerReadFailure_c

Power reading could not be performed. Data in gapConnectionEvent_t.eventData.failReason.

enumerator gConnEvtParameterUpdateRequest_c

A connection parameter update request has been received. Data in gapConnectionEvent_t.eventData.connectionUpdateRequest.

enumerator gConnEvtParameterUpdateComplete_c

The connection has new parameters. Data in gapConnectionEvent_t.eventData.connectionUpdateComplete.

enumerator gConnEvtLeDataLengthChanged_c

The new TX/RX Data Length parameters. Data in gapConnectionEvent_t.eventData.rssi_dBm.leDataLengthChanged.

enumerator gConnEvtLeScOobDataRequest_c

Event sent to request LE SC OOB Data (r, Cr and Addr) received from a peer.

enumerator gConnEvtLeScDisplayNumericValue_c

Event sent to display and confirm a Numeric Comparison Value when using the LE SC Numeric Comparison pairing method.

enumerator gConnEvtLeScKeypressNotification_c

Remote Keypress Notification received during Passkey Entry Pairing Method.

enumerator gConnEvtChannelMapRead_c

Channel Map was read for a connection. Data is contained in gapConnectionEvent_t.eventData.channelMap

enumerator gConnEvtChannelMapReadFailure_c

Channel Map reading could not be performed. Data in gapConnectionEvent_t.eventData.failReason.

enumerator gConnEvtChanSelectionAlgorithm2_c

LE Channel Selection Algorithm #2 is used on the data channel connection.

enumerator gConnEvtPairingNoLtk_c

No LTK was found for the Central peer. Pairing shall be performed again.

enumerator gConnEvtPairingAlreadyStarted_c

Pairing process was already started

enumerator gConnEvtIqReportReceived_c

Controller has reported IQ information received from a connected peer. Data in gapConnectionEvent_t.eventData.connIqReport.

enumerator gConnEvtCteRequestFailed_c

CTE Request to a connected peer has failed. Data in gapConnectionEvent_t.eventData.cteRequestFailedEvent.

enumerator gConnEvtCteReceiveParamsSetupComplete_c

Connection CTE receive parameters have been successfully set.

enumerator gConnEvtCteTransmitParamsSetupComplete_c

Connection CTE transmit parameters have been successfully set.

enumerator gConnEvtCteReqStateChanged_c

Controller started or stopped initiating the CTE Request procedure.

enumerator gConnEvtCteRspStateChanged_c

Controller enabled or disabled sending CTE Responses for a connection.

enumerator gConnEvtPathLossThreshold_c

Received a Path Loss Threshold event. Data in gapConnectionEvent_t.eventData.pathLossThreshold.

enumerator gConnEvtTransmitPowerReporting_c

Received a Transmit Power report. Data in gapConnectionEvent_t.eventData.transmitPowerReporting.

enumerator gConnEvtEnhancedReadTransmitPowerLevel_c

Local information has been read from Controller. Data in gapConnectionEvent_t.eventData.transmitPowerInfo.

enumerator gConnEvtPathLossReportingParamsSetupComplete_c

Path Loss Reporting parameters have been successfully set.

enumerator gConnEvtPathLossReportingStateChanged_c

Path Loss Reporting has been enabled or disabled.

enumerator gConnEvtTransmitPowerReportingStateChanged_c

Transmit Power Reporting has been enabled or disabled for local and/or remote Controllers.

enumerator gConnEvtEattConnectionRequest_c

Received Enhanced Connection Request for EATT channels.

enumerator gConnEvtEattConnectionComplete_c

Received Enhanced Connection Response for EATT channels.

enumerator gConnEvtEattChannelReconfigureResponse_c

Received Enhanced Channel Reconfigure Response for EATT channels.

enumerator gConnEvtEattBearerStatusNotification_c

Enhanced Bearer status updated

enumerator gConnEvtHandoverConnected_c

A connection has been established through the Handover feature. Data in gapConnectionEvent_t.eventData.handoverConnectedEvent.

enumerator gHandoverDisconnected_c

A connection has been terminated as a result of connection handover.

enumerator gConnEvtLeSetDataLengthFailure_c

The Set Data Length command has failed.

enumerator gConnEvtSmError_c

Security Manager error occured.

enumerator gConnEvtLeSubrateChange_c

The connection has new parameters. Data in gapConnectionEvent_t.eventData.gapSubrateChangeEvent.

enumerator gConnEvtLeSetLocalPeripheralLatencyEnableComplete_c

Le Set Local Peripheral Latency Enable complete. Data in gapConnectionEvent_t.eventData.leSetLocalPeripheralLatencyEnableComplete.

enumerator gConnEvtRemoteFeaturesRead_c

enum gapEattBearerStatus_t

Enumeration for Bearer Status Notification command status.

Values:

enumerator gEnhancedBearerActive_c

enumerator gEnhancedBearerSuspendedNoLocalCredits_c

enumerator gEnhancedBearerNoPeerCredits_c

enumerator gEnhancedBearerDisconnected_c

enumerator gEnhancedBearerStatusEnd_c

enum gapCarSupport_t

Central Address Resolution characteristic state

Values:

enumerator CAR_Unknown

The Central Address Resolution characteristic was not read

enumerator CAR_Unavailable

The device tried to read the Central Address Resolution characteristic, but it's unavailable

enumerator CAR_Unsupported

The device has read the Central Address Resolution characteristic, and the it's value is FALSE

enumerator CAR_Supported

The device has read the Central Address Resolution characteristic, and the it's value is TRUE

enum gapPeriodicAdvListOperation_t

Values:

enumerator gAddDevice_c

enumerator gRemoveDevice_c

enumerator gRemoveAllDevices_c

enum gapAppearance_tag

Appearance characteristic enumeration, also used in advertising.

Values:

enumerator gUnknown_c

enumerator gGenericPhone_c

enumerator gGenericComputer_c

enumerator gGenericWatch_c

enumerator gSportsWatch_c

enumerator gGenericClock_c

enumerator gGenericDisplay_c

enumerator gGenericRemoteControl_c

enumerator gGenericEyeglasses_c

enumerator gGenericTag_c

enumerator gGenericKeyring_c

enumerator gGenericMediaPlayer_c

enumerator gGenericBarcodeScanner_c

enumerator gGenericThermometer_c

enumerator gThermometerEar_c

enumerator gGenericHeartrateSensor_c

enumerator gHeartRateSensorHeartRateBelt_c

enumerator gGenericBloodPressure_c

enumerator gBloodPressureArm_c

enumerator gBloodPressureWrist_c

enumerator gHumanInterfaceDevice_c

enumerator gKeyboard_c

enumerator gMouse_c

enumerator gJoystick_c

enumerator gGamepad_c

enumerator gDigitizerTablet_c

enumerator gCardReader_c

enumerator gDigitalPen_c

enumerator gBarcodeScanner_c

enumerator gGenericGlucoseMeter_c

enumerator gGenericRunningWalkingSensor_c

enumerator gRunningWalkingSensorInShoe_c

enumerator gRunningWalkingSensorOnShoe_c

enumerator gRunningWalkingSensorOnHip_c

enumerator gGenericCycling_c

enumerator gCyclingComputer_c

enumerator gCyclingSpeedSensor_c

enumerator gCyclingCadenceSensor_c

enumerator gCyclingPowerSensor_c

enumerator gCyclingSpeedandCadenceSensor_c

enumerator gGenericPulseOximeter_c

enumerator gFingertip_c

enumerator gWristWorn_c

enumerator gGenericWeightScale_c

enumerator gGenericOutdoorSportsActivity_c

enumerator gLocationDisplayDevice_c

enumerator gLocationandNavigationDisplayDevice_c

enumerator gLocationPod_c

enumerator gLocationAndNavigationPod_c

typedef uint8_t gapIoCapabilities_t

I/O Capabilities as defined by the SMP

typedef uint8_t gapSmpKeyFlags_t

Flags indicating the Keys to be exchanged by the SMP during the key exchange phase of pairing.

typedef uint8_t gapSecurityMode_t

LE Security Mode

typedef uint8_t gapSecurityLevel_t

LE Security Level

typedef uint8_t gapSecurityModeAndLevel_t

Security Mode-and-Level definitions

typedef uint8_t gapKeypressNotification_t

Keypress Notification Types

typedef enum *gapKeypressNotification_tag* gapKeypressNotification_tag

typedef uint8_t gapAuthenticationRejectReason_t

Reason for rejecting the pairing request.

typedef struct *gapExtAdvertisingParameters_tag* gapExtAdvertisingParameters_t

Extended Advertising Parameters; for defaults see gGapDefaultExtAdvertisingParameters_d.

typedef struct *gapPeriodicAdvParameters_tag* gapPeriodicAdvParameters_t

Periodic Advertising Parameters [v2]; for defaults see gGapDefaultPeriodicAdvParameters_d.

typedef enum *gapPeriodicAdvSyncMode_tag* gapPeriodicAdvSyncMode_t

Periodic Advertisement Sync Transfer parameters

typedef struct *gapPeriodicAdvSyncTransfer_tag* gapPeriodicAdvSyncTransfer_t

typedef struct *gapPeriodicAdvSetInfoTransfer_tag* gapPeriodicAdvSetInfoTransfer_t

typedef struct *gapSetPeriodicAdvSyncTransferParams_tag*
gapSetPeriodicAdvSyncTransferParams_t

typedef uint8_t gapCreateSyncReqFilterPolicy_t

Create Sync Request Filter Policy values

typedef struct *gapCreateSyncReqOptions_tag* gapCreateSyncReqOptions_t

Create Sync Request Options

typedef struct *gapPeriodicAdvSyncReq_tag* gapPeriodicAdvSyncReq_t

Periodic Advertising Sync Request parameters

typedef uint8_t gapAdTypeFlags_t

Values of the AD Flags advertising data structure.

typedef uint8_t gapDecisionInstructionsAdvMode_t

typedef struct *gapDecisionInstructionsData_tag* gapDecisionInstructionsData_t

typedef *gapAdvertisingData_t* gapScanResponseData_t

Scan Response Data structure : a list of several *gapAdStructure_t* structures.

typedef uint8_t gapControllerTestTxType_t

Enumeration for Controller Transmitter Test payload types.

typedef *bleResult_t* gapDisconnectionReason_t

Disconnection reason alias - reasons are contained in HCI error codes.

typedef void (*gapAdvertisingCallback_t)(*gapAdvertisingEvent_t* *pAdvertisingEvent)

Advertising Callback prototype.

typedef void (*gapScanningCallback_t)(*gapScanningEvent_t* *pScanningEvent)

Scanning Callback prototype.

typedef void (*gapConnectionCallback_t)(*deviceId_t* deviceId, *gapConnectionEvent_t* *pConnectionEvent)

Connection Callback prototype.

typedef enum *gapAppearance_tag* gapAppearance_t

Appearance characteristic enumeration, also used in advertising.

typedef struct *gapHostVersion_tag* gapHostVersion_t

bleResult_t Gap_SetDataRelatedAddressChanges(uint8_t advertisingHandle, uint8_t changeReasons)

Command specifies circumstances when the Controller shall refresh any Resolvable Private Address used by the advertising set identified by the Advertising_Handle parameter.

Parameters

- advertisingHandle – **[in]** Identify an advertising set.
- changeReasons – **[in]** Change reasons. Any combination of gAdvDataChange_c and gScanRspDataChange_c. 0U to disable the feature.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range

bleResult_t Gap_LeChasConfig(int8_t initialFilterSeed, uint8_t filterThreshold, uint8_t filterWeight, uint16_t measurementInterval)

Command to configure Channel Assessment settings.

Parameters

- initialFilterSeed – **[in]** Initial filter seed (-108 to -80 dBm).
- filterThreshold – **[in]** Filter threshold (not used).
- filterWeight – **[in]** Filter weight (1 to 255).

- measurementInterval – **[in]** Measurement interval (0 to 0x7FFF).

Return values

bleResult_t – gBleSuccess_c or error.

bleResult_t Gap_LeModulationTest(uint8_t testMode, uint8_t channelNumber, uint8_t options, int8_t txPower)

Command to transmit continuously unmodulated or modulated signal or measure the RSSI of a channel.

Parameters

- testMode – **[in]** Test mode (0=disable, 1=unmodulated, 2=mod 0's, 3=mod 1's, 4=mod PRBS, 255=RSSI measurement).
- channelNumber – **[in]** Channel number (0-39 for BLE RF, 0-127 for generic).
- options – **[in]** Options bitmap (bit0=PHY, bit1=channel type, bit2=power type).
- txPower – **[in]** TX power in dBm or power index (0-62) based on options.

Return values

bleResult_t – gBleSuccess_c or error.

bleResult_t Gap_RegisterDeviceSecurityRequirements(const *gapDeviceSecurityRequirements_t* *pSecurity)

Registers the device security requirements. This function includes a central security for all services and, optionally, additional stronger security settings for services as required by the profile and/or application.

Remark

pSecurity or any other contained security structure pointers that are NULL are ignored, i.e., defaulted to No Security (Security Mode 1 Level 1, No Authorization, Minimum encryption key size). This function executes synchronously.

Parameters

- pSecurity – **[in]** A pointer to the application-allocated *gapDeviceSecurityRequirements_t* structure.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range

bleResult_t Gap_SetAdvertisingParameters(const *gapAdvertisingParameters_t* *pAdvertisingParameters)

Sets up the Advertising Parameters.

Remark

GAP Peripheral-only API function.

Parameters

- pAdvertisingParameters – **[in]** Pointer to *gapAdvertisingParameters_t* structure.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range
- gBleOutOfMemory_c – Cannot allocate memory for the Host task
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version

bleResult_t Gap_SetAdvertisingData(const *gapAdvertisingData_t* *pAdvertisingData, const *gapScanResponseData_t* *pScanResponseData)

Sets up the Advertising and Scan Response Data.

Remark

Any of the parameters may be NULL, in which case they are ignored. Therefore, this function can be used to set any of the parameters individually or both at once. The standard advertising packet payload is 37 bytes. Some of the payload may be occupied by the Advertiser Address which takes up 6 bytes and for some advertising PDU types also by the Initiator Address which takes another 6 bytes. This leaves 25-31 bytes to the application to include advertising structures (Length [1Byte], AD Type [1 Byte], AD Data[Length-1 Bytes])

Remark

GAP Peripheral-only API function.

Parameters

- pAdvertisingData – **[in]** Pointer to *gapAdvertisingData_t* structure or NULL.
- pScanResponseData – **[in]** Pointer to gapScanResponseData_t structure or NULL.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range
- gGapAdvDataTooLong_c – The advertising data length is too big
- gBleOutOfMemory_c – Cannot allocate memory for the Host task
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version

bleResult_t Gap_StartAdvertising(*gapAdvertisingCallback_t* advertisingCallback, *gapConnectionCallback_t* connectionCallback)

Commands the controller to start advertising.

Remark

The advertisingCallback confirms or denies whether the advertising has started. The connectionCallback is only used if a connection gets established during advertising.

Remark

GAP Peripheral-only API function.

Parameters

- advertisingCallback – **[in]** Callback used by the application to receive advertising events. Can be NULL.
- connectionCallback – **[in]** Callback used by the application to receive connection events. Can be NULL.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleInvalidState_c – Advertising is already started or pending to be started
- gBleOutOfMemory_c – Cannot allocate memory for the Host task
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version

bleResult_t Gap_StopAdvertising(void)

Commands the controller to stop advertising.

Remark

GAP Peripheral-only API function.

Return values

- gBleSuccess_c –
- gBleInvalidState_c – Advertising is already stopped or pending to be stopped
- gBleOutOfMemory_c – Cannot allocate memory for the Host task
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version

bleResult_t Gap_Authorize(*deviceId_t* deviceId, uint16_t handle, *gattDbAccessType_t* access)

Authorizes a peer for an attribute in the database.

Remark

This function executes synchronously.

Remark

GATT Server-only API function.

Parameters

- deviceId – **[in]** The peer being authorized.
- handle – **[in]** The attribute handle.
- access – **[in]** The type of access granted (gAccessRead_c or gAccessWrite_c).

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range
- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory
- gBleInvalidParameter_c – The deviceId parameter is not valid or the access parameter is not gAccessRead_c or gAccessWrite_c
- gBleUnexpectedError_c – Saving to NVM failed (module not initialized or corrupted NVM)
- gBleOverflow_c – the number of handles to be read or written from the NVM is bigger than gcGapMaxAuthorizationHandles_c
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version

bleResult_t Gap_SaveCccd(*deviceId_t* deviceId, uint16_t handle, *gattCccdFlags_t* cccd)

Save the CCCD value for a specific Client and CCCD handle.

Remark

The GATT Server layer saves the CCCD value automatically when it is written by the Client. This API should only be used to save the CCCD in other situations, e.g., when for some reason the application decides to disable notifications/indications for a specific Client.

Remark

This function executes synchronously.

Remark

GATT Server-only API function.

Parameters

- deviceId – **[in]** The peer GATT Client.
- handle – **[in]** The handle of the CCCD as defined in the GATT Database.
- cccd – **[in]** The bit mask representing the CCCD value to be saved.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range
- gBleUnexpectedError_c – Saving to NVM failed (module not initialized or corrupted NVM)
- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory
- gDevDbCccdLimitReached_c – No more room in NVM

bleResult_t Gap_CheckNotificationStatus(*deviceId_t* deviceId, uint16_t handle, bool_t *pOutIsActive)

Retrieves the notification status for a given Client and a given CCCD handle.

Remark

This function executes synchronously.

Remark

GATT Server-only API function.

Parameters

- deviceId – **[in]** The peer GATT Client.
- handle – **[in]** The handle of the CCCD.
- pOutIsActive – **[out]** The address to store the status into.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range
- gDevDbCccdNotFound_c – The handle is not CCCD
- gBleUnavailable_c – The bond data entry for this device is corrupted

bleResult_t Gap_CheckIndicationStatus(*deviceId_t* deviceId, uint16_t handle, bool_t *pOutIsActive)

Retrieves the indication status for a given Client and a given CCCD handle.

Remark

This function executes synchronously.

Remark

GATT Server-only API function.

Parameters

- deviceId – **[in]** The peer GATT Client.
- handle – **[in]** The handle of the CCCD.
- pOutIsActive – **[out]** The address to store the status into.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gDevDbCccdNotFound_c – The handle is not CCCD.
- gBleUnavailable_c – The bond data entry for this device is corrupted.

bleResult_t Gap_GetBondedDevicesIdentityInformation(*gapIdentityInformation_t* *aOutIdentityAddresses, uint8_t maxDevices, uint8_t *pOutActualCount)

Retrieves a list of the identity information of bonded devices, if any.

Remark

This API may be useful when creating a filter accept list or a resolving list.

Remark

This function executes synchronously.

Parameters

- aOutIdentityAddresses – **[out]** Array of identities to be filled.
- maxDevices – **[in]** Maximum number of identities to be obtained.
- pOutActualCount – **[out]** The actual number of identities written.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleInvalidParameter_c – A parameter has an invalid value, is outside the accepted range, or the NVM entry is invalid

bleResult_t Gap_Pair(*deviceId_t* deviceId, const *gapPairingParameters_t* *pPairingParameters)

Initiates pairing with a peer device.

Remark

GAP Central-only API function.

Parameters

- deviceId – **[in]** The peer to pair with.
- pPairingParameters – **[in]** Pairing parameters as required by the SMP.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range
- gBleOutOfMemory_c – Cannot allocate memory for the Host task

bleResult_t Gap_SendPeripheralSecurityRequest(*deviceId_t* deviceId, const *gapPairingParameters_t* *pPairingParameters)

Informs the peer Central about the local security requirements.

Remark

The procedure has the same parameters as the pairing request, but, because it is initiated by the Peripheral, it has no pairing effect. It only informs the Central about the requirements.

Remark

GAP Peripheral-only API function.

Parameters

- deviceId – **[in]** The GAP peer to pair with.
- pPairingParameters – **[in]** Pairing parameters as required by the SMP.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleOutOfMemory_c – Cannot allocate memory for the Host task

bleResult_t Gap_EncryptLink(*deviceId_t* deviceId)

Encrypts the link with a bonded peer.

Remark

GAP Central-only API function.

Parameters

- deviceId – **[in]** Device ID of the peer.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gGapDeviceNotBonded_c – Trying to execute an API that is only available for bonded devices.

bleResult_t Gap_EncryptLinkTak(*deviceId_t* deviceId, uint8_t *pTak)

Encrypts the link using a Transient Application Key.

Parameters

- deviceId – **[in]** Device ID of the peer.
- ptak – **[in]** Pointer to the Transient Key.

Return values

bleResult_t – gBleSuccess_c or error.

bleResult_t Gap_AcceptPairingRequest(*deviceId_t* deviceId, const *gapPairingParameters_t* *pPairingParameters)

Accepts the pairing request from a peer.

Remark

This should be called in response to a gPairingRequest_c event.

Remark

GAP Peripheral-only API function.

Parameters

- deviceId – **[in]** The peer requesting authentication.
- pPairingParameters – **[in]** Pairing parameters as required by the SMP.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_RejectPairing(*deviceId_t* deviceId, *gapAuthenticationRejectReason_t* reason)

Rejects the peer's authentication request.

Parameters

- deviceId – **[in]** The GAP peer who requested authentication.
- reason – **[in]** Reason why the current device rejects the authentication.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_EnterPasskey(*deviceId_t* deviceId, uint32_t passkey)

Enters the passkey requested by the peer during the pairing process.

Parameters

- deviceId – **[in]** The GAP peer that requested a passkey entry.
- passkey – **[in]** The peer's secret passkey.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_ProvideOob(*deviceId_t* deviceId, const uint8_t *aOob)

Provides the Out-Of-Band data for the SMP Pairing process.

Parameters

- deviceId – **[in]** The pairing device.
- aOob – **[in]** Pointer to OOB data (array of gcSmpOobSize_c size).

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_RejectPasskeyRequest(*deviceId_t* deviceId)

Rejects the passkey request from a peer.

Remark

GAP Central-only API function.

Parameters

- deviceId – **[in]** The GAP peer that requested a passkey entry.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SendSmpKeys(*deviceId_t* deviceId, const *gapSmpKeys_t* *pKeys)

Sends the SMP keys during the SMP Key Exchange procedure.

Parameters

- deviceId – **[in]** The GAP peer who initiated the procedure.
- pKeys – **[in]** The SMP keys of the local device.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_RejectKeyExchangeRequest(*deviceId_t* deviceId)

Rejects the Key Exchange procedure with a paired peer.

Parameters

- deviceId – **[in]** The GAP peer who requested the Key Exchange procedure.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeScRegeneratePublicKey(void)

Regenerates the private/public key pair used for LE Secure Connections pairing.

Remark

The application should listen for the gLeScPublicKeyRegenerated_c generic event.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeScValidateNumericValue(*deviceId_t* deviceId, bool_t valid)

Validates the numeric value during the Numeric Comparison LE Secure Connections pairing.

Parameters

- deviceId – **[in]** Device ID of the peer.
- valid – **[in]** TRUE if user has indicated that numeric values are matched, FALSE otherwise.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeScGetLocalOobData(void)

Retrieves local OOB data used for LE Secure Connections pairing.

Remark

The application should listen for the gLeScLocalOobData_c generic event.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeScSetPeerOobData(*deviceId_t* deviceId, const *gapLeScOobData_t* *pPeerOobData)

Sets peer OOB data used for LE Secure Connections pairing.

Remark

This function should be called in response to the gConnEvtLeScOobDataRequest_c event.

Parameters

- deviceId – **[in]** Device ID of the peer.
- pPeerOobData – **[in]** OOB data received from the peer.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_LeScSendKeypressNotification(*deviceId_t* deviceId, *gapKeypressNotification_t* keypressNotification)

Sends a Keypress Notification to the peer.

Remark

This function shall only be called during the passkey entry process and only if both peers support Keypress Notifications.

Parameters

- deviceId – **[in]** Device ID of the peer.
- keypressNotification – **[in]** Value of the Keypress Notification.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_ProvideLongTermKey(*deviceId_t* deviceId, const uint8_t *aLtk, uint8_t ltkSize)

Provides the Long Term Key (LTK) to the controller for encryption setup.

Remark

The application should provide the same LTK used during bonding with the respective peer.

Remark

GAP Peripheral-only API function.

Parameters

- deviceId – **[in]** The GAP peer who requested encryption.
- aLtk – **[in]** The Long Term Key.
- ltkSize – **[in]** The Long Term Key size.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_ProvideLongTermKeyTak(*deviceId_t* deviceId, const uint8_t *aLtk, uint8_t ltkSize)

Provides the Long Term Key (TAK) to the controller for encryption setup. GAP Peripheral-only API function.

Parameters

- deviceId – **[in]** The GAP peer who requested encryption.
- aLtk – **[in]** The Transient Application Key.
- ltkSize – **[in]** The Transient Application Key size.

Return values

bleResult_t – gBleSuccess_c or error.

bleResult_t Gap_DenyLongTermKey(*deviceId_t* deviceId)

Rejects an LTK request originating from the controller.

Remark

GAP Peripheral-only API function.

Parameters

- deviceId – **[in]** The GAP peer who requested encryption.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LoadEncryptionInformation(*deviceId_t* deviceId, uint8_t *aOutLtk, uint8_t *pOutLtkSize)

Loads the encryption key for a bonded device.

Remark

This function executes synchronously.

Parameters

- deviceId – **[in]** Device ID of the peer.
- aOutLtk – **[out]** Array of size gcMaxLtkSize_d to be filled with the LTK.
- pOutLtkSize – **[out]** The LTK size.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleUnavailable_c – The bond data entry for this device is corrupted.

bleResult_t Gap_SetLocalPasskey(uint32_t passkey)

Sets the SMP passkey for this device.

Remark

This is the PIN that the peer's user must enter during pairing.

Remark

This function executes synchronously.

Remark

GAP Peripheral-only API function.

Parameters

- passkey – **[in]** The SMP passkey.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gSmInvalidDeviceId_c – The device ID is not valid or it has been disconnected in the meantime.
- gSmInvalidCommandCode_c – An invalid internal state machine code was requested.
- gSmPairingAlreadyStarted_c – Pairing process was already started.
- gSmInvalidInternalOperation_c – A memory corruption or invalid operation may have occurred.
- gSmSmpTimeoutOccurred_c – An SMP timeout has occurred for the peer device.
- gSmInvalidCommandParameter_c – One of the parameters of the SM command is not valid.
- gSmCommandNotSupported_c – The Security Manager does not have the required features or version to support this command
- gSmUnexpectedCommand_c – This command is not or cannot be handled in the current context of the SM.
- gSmSmpPacketReceivedAfterTimeoutOccurred_c – A SMP packet has been received from a peer device for which a pairing procedure has timed out.
- gSmUnexpectedPairingTerminationReason_c – The upper layer tried to cancel the pairing procedure with an unexpected pairing failure reason for the current phase of the pairing procedure.

bleResult_t Gap_SetScanMode(*gapScanMode_t* scanMode, *gapAutoConnectParams_t* *pAutoConnectParams, *gapConnectionCallback_t* connCallback)

Sets internal scan filters and actions.

Remark

This function can be called before Gap_StartScanning. If this function is never called, then the default value of gDefaultScan_c is considered and all scanned devices are reported to the application without any additional filtering or action.

Remark

This function executes synchronously.

Remark

GAP Central-only API function.

Parameters

- scanMode – **[in]** The scan mode to be activated. Default is gDefaultScan_c.
- pAutoConnectParams – **[in]** Pointer to the *gapAutoConnectParams_t* structures if scanMode is set to gAutoConnect_c. The memory used must be persistent and should not change during the next scan periods or until another Gap_SetScanMode is called.
- connCallback – **[in]** Auto-Connect callback. Must be set if scanMode is set to gAutoConnect_c.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_SetDecisionInstructions(uint8_t numTest, const *gapDecisionInstructionsData_t* *pDecisionInstructions)

Sets up the Decision Instructions.

Remark

GAP Central-only API function.

Remark

Application should wait for gDecisionInstructionsSetupComplete_c generic event or for gInternalError_c generic event with errorSource = gSetDecisionInstructions_c.

Parameters

- numTest – **[in]** The number of tests in the decision instructions.
- pDecisionInstructions – **[in]** Pointer to an array of gapDecisionInstructionsData_t structures. containing decision instruction for each test.

Return values

- gBleFeatureNotSupported_c – in case gLeExtendedAdv_c or gLeDecisionBasedAdvertisingFiltering_c are not supported.
- gBleInvalidParameter_c – in case at least 1 parameter is incorrect.
- gBleOutOfMemory_c – in case the memory allocation for the app to host message fails.
- gBleSuccess_c – otherwise.

bleResult_t Gap_InitMonitoringAdvertisers(void)

Initialize function table for Monitored Advertisers functionality.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Feature is not supported.

bleResult_t Gap_AddDeviceToMonAdvList(*bleAddressType_t* addressType, *bleDeviceAddress_t* address, int8_t rssiLowThreshold, int8_t rssiHighThreshold, uint8_t timeout)

This function adds a device to the Monitored Advertisers List.

Parameters

- addressType – **[in]** Address type of the device.
- address – **[in]** Address of the device.
- rssiLowThreshold – **[in]** RSSI low threshold value.
- rssiHighThreshold – **[in]** RSSI high threshold value.
- timeout – **[in]** Timeout value.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – One or more parameters are invalid.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_RemoveDeviceFromMonAdvList(*bleAddressType_t* addressType, *bleDeviceAddress_t* address)

This function removes a device from the Monitored Advertisers List.

Parameters

- addressType – **[in]** Address type of the device.
- address – **[in]** Address of the device.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – One or more parameters are invalid.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_ClearMonAdvList(void)

This function clears the Monitored Advertisers List.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnableMonAdv(bool_t enable)

This function enables or disables monitoring of advertisers.

Parameters

- enable – **[in]** Enable or disable monitoring.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_ReadMonAdvListSize(void)

This function reads the size of the Monitored Advertisers List.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_StartScanning(const *gapScanningParameters_t* *pScanningParameters, *gapScanningCallback_t* scanningCallback, *gapFilterDuplicates_t* enableFilterDuplicates, uint16_t duration, uint16_t period)

Optionally sets the scanning parameters and begins scanning.

Remark

Use this API to both set the scanning parameters and start scanning. If pScanningParameters is NULL, scanning is started with the existing settings.

Remark

GAP Central-only API function.

Parameters

- pScanningParameters – **[in]** The scanning parameters; may be NULL.
- scanningCallback – **[in]** The scanning callback.
- enableFilterDuplicates – **[in]** Enable or disable duplicate advertising report filtering
- duration – **[in]** Scan duration expressed in units of 10 ms. Set 0 for continuous scan until explicitly disabled. Used only for BLE5.0, otherwise ignored.
- period – **[in]** Time interval expressed in units of 1.28 seconds from when the Controller started its last Scan_Duration until it begins the subsequent Scan_Duration. Set 0 to disable periodic scanning. Used only for BLE5.0, otherwise ignored.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidState_c – The requested API cannot be called in the current state, scanning was already started.

bleResult_t Gap_StopScanning(void)

Commands the controller to stop scanning.

Remark

GAP Central-only API function.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidState_c – The requested API cannot be called in the current state, scanning is in the process of stopping.

bleResult_t Gap_Connect(const *gapConnectionRequestParameters_t* *pParameters, *gapConnectionCallback_t* connCallback)

Connects to a scanned device.

Remark

GAP Central-only API function.

Parameters

- pParameters – **[in]** Create Connection command parameters.
- connCallback – **[in]** Callback used to receive connection events.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_ConnectFromPawr(const *gapConnectionFromPawrParameters_t* *pParameters, *gapConnectionCallback_t* connCallback)

Connects to a device which is doing periodic advertising with responses.

Remark

GAP Central-only API function.

Parameters

- pParameters – **[in]** Create Connection command parameters.
- connCallback – **[in]** Callback used to receive connection events.

Return values

- gBleSuccess_c –

- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_Disconnect(*deviceId_t* deviceId)

Initiates disconnection from a connected peer device.

Parameters

- deviceId – **[in]** The connected peer to disconnect from.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SaveCustomPeerInformation(*deviceId_t* deviceId, const uint8_t *pInfo, uint16_t offset, uint16_t infoSize)

Saves custom peer information in raw data format.

Remark

This function can be called by the application to save custom information about the peer device, e.g., Service Discovery data (to avoid doing it again on reconnection).

Remark

This function executes synchronously.

Parameters

- deviceId – **[in]** Device ID of the GAP peer.
- pInfo – **[in]** Pointer to the beginning of the data.
- offset – **[in]** Offset from the beginning of the reserved memory area.
- infoSize – **[in]** Data size (maximum equal to gcReservedFlashSizeForCustomInformation_d).

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory.

bleResult_t Gap_LoadCustomPeerInformation(*deviceId_t* deviceId, uint8_t *pOutInfo, uint16_t offset, uint16_t infoSize)

Loads the custom peer information in raw data format.

Remark

This function can be called by the application to load custom information about the peer device, e.g., Service Discovery data (to avoid doing it again on reconnection).

Remark

This function executes synchronously.

Parameters

- deviceId – **[in]** Device ID of the GAP peer.
- pOutInfo – **[out]** Pointer to the beginning of the allocated memory.
- offset – **[in]** Offset from the beginning of the reserved memory area.
- infoSize – **[in]** Data size (maximum equal to gcReservedFlashSizeForCustomInformation_d).

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleUnavailable_c – The bond data entry for this device is corrupted.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory.

bleResult_t Gap_LoadCustomBondedDeviceInformation(uint8_t nvmIndex, uint8_t *pOutInfo, uint16_t offset, uint16_t infoSize)

Loads the custom bonded device information in raw data format. Unlike Gap_LoadCustomPeerInformation, it does not require an active connection.

Remark

This function can be called by the application to load custom information about the bonded device.

Remark

This function executes synchronously.

Parameters

- nvmIndex – **[in]** Index of the device in NVM bonding area.
- pOutInfo – **[out]** Pointer to the beginning of the allocated memory.
- offset – **[in]** Offset from the beginning of the reserved memory area.
- infoSize – **[in]** Data size (maximum equal to gcReservedFlashSizeForCustomInformation_d).

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleUnavailable_c – The bond data entry for this device is corrupted.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory.

bleResult_t Gap_CheckIfBonded(*deviceId_t* deviceId, bool_t *pOutIsBonded, uint8_t *pOutNvmIndex)

Returns whether or not a connected peer device is bonded and the NVM index.

Remark

This function executes synchronously.

Parameters

- deviceId – **[in]** Device ID of the GAP peer.
- pOutIsBonded – **[out]** Boolean to be filled with the bonded flag.
- pOutNvmIndex – **[out]** If bonded, to be filled optionally with the NVM index.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_CheckIfConnected(*bleAddressType_t* addressType, const *bleDeviceAddress_t* aAddress, bool_t addrResolved, bool_t *pOutIsConnected)

Checks if a connection exists between the local device and another device that has the provided address information. This function executes synchronously.

Parameters

- addressType – **[in]** Peer address type
- aAddress – **[in]** Peer address
- addrResolved – **[in]** Set to TRUE if the address contained in the addressType and aAddress fields is the identity address of a resolved RPA.
- pOutIsConnected – **[out]** TRUE if the device is found

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_CheckNvmIndex(uint8_t nvmIndex, bool_t *pOutIsFree)

Returns whether or not the given NVM index is free.

Remark

This function executes synchronously.

Parameters

- nvmIndex – **[in]** NVM index.
- pOutIsFree – **[out]** TRUE if free, FALSE if occupied.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_ReadFilterAcceptListSize(void)

Retrieves the size of the Filter Accept List.

Remark

Response is received in the gFilterAcceptListSizeRead_c generic event.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_ClearFilterAcceptList(void)

Removes all addresses from the Filter Accept List, if any.

Remark

Confirmation is received in the gFilterAcceptListCleared_c generic event.

Return values

gBleSuccess_c –

bleResult_t Gap_AddDeviceToFilterAcceptList(*bleAddressType_t* addressType, const *bleDeviceAddress_t* address)

Adds a device address to the Filter Accept List.

Parameters

- address – **[in]** The address of the filter accept listed device.
- addressType – **[in]** The device address type (public or random).

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_RemoveDeviceFromFilterAcceptList(*bleAddressType_t* addressType, const *bleDeviceAddress_t* address)

Removes a device address from the Filter Accept List.

Parameters

- address – **[in]** The address of the filter accept listed device.
- addressType – **[in]** The device address type (public or random).

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_ReadPublicDeviceAddress(void)

Reads the device's public address from the controller.

Remark

The application should listen for the gPublicAddressRead_c generic event.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_CreateRandomDeviceAddress(const uint8_t *aIrk, const uint8_t *aRandomPart)

Requests the controller to create a random address.

Remark

The application should listen for the gRandomAddressReady_c generic event. Note that this does not set the random address in the Controller. To set the random address, call *Gap_SetRandomAddress()* with the generated address contained in the event data.

Parameters

- aIrk – **[in]** The Identity Resolving Key to be used for a private resolvable address or NULL for a private non-resolvable address (fully random).
- aRandomPart – **[in]** If aIrk is not NULL, this is a 3-byte array containing the Random Part of a Private Resolvable Address, in LSB to MSB order; the most significant two bits of the most significant byte (aRandomPart[3] & 0xC0) are ignored. This may be NULL, in which case the Random Part is randomly generated internally.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SaveDeviceName(*deviceId_t* deviceId, const uchar_t *pName, uint8_t cNameSize)

Store the name of a bonded device.

Remark

This function copies cNameSize characters from the pName array and adds the NULL character to terminate the string.

Remark

This function executes synchronously.

Parameters

- deviceId – **[in]** Device ID for the active peer which name is saved.
- pName – **[in]** Array of characters holding the name.
- cNameSize – **[in]** Number of characters to be saved.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory.

bleResult_t Gap_GetBondedDevicesCount(uint8_t *pOutBondedDevicesCount)

Retrieves the number of bonded devices.

Remark

This function executes synchronously.

Parameters

- pOutBondedDevicesCount – **[out]** Pointer to integer to be written.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_GetBondedDeviceName(uint8_t nvmIndex, uchar_t *pOutName, uint8_t maxNameSize)

Retrieves the name of a bonded device.

Remark

nvmIndex is an integer ranging from 0 to N-1, where N is the number of bonded devices and can be obtained by calling Gap_GetBondedDevicesCount(&N).

Remark

This function executes synchronously.

Parameters

- nvmIndex – **[in]** Index of the device in NVM bonding area.
- pOutName – **[out]** Destination array to copy the name into.
- maxNameSize – **[in]** Maximum number of characters to be copied, including the terminating NULL character.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleUnavailable_c – The bond data entry for this device is corrupted.

bleResult_t Gap_SetBondedDeviceName(uint8_t nvmIndex, const uchar_t *pName, uint8_t cNameSize)

Store the name of a bonded device.

Remark

This function copies cNameSize characters from the pName array and adds the NULL character to terminate the string.

Remark

This function executes synchronously.

Parameters

- nvmIndex – **[in]** Index of the device in NVM bonding area.
- pName – **[in]** Array of characters holding the name.
- cNameSize – **[in]** Number of characters to be saved.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory.

bleResult_t Gap_RemoveBond(uint8_t nvmIndex)

Removes the bond with a device.

Remark

This API requires that there are no active connections at call time. The *Gap_CheckIfBonded()* API can be called to obtain the nvmIndex of a bonded peer.

Remark

This function executes synchronously.

Parameters

- nvmIndex – **[in]** Index of the device in the NVM bonding area.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleUnavailable_c – The bond data entry for this device is corrupted.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleInvalidState_c – The bond is not active.

bleResult_t Gap_RemoveAllBonds(void)

Removes all bonds with other devices.

Remark

This API requires that there are no active connections at call time.

Remark

This function executes synchronously.

Return values

- gBleSuccess_c –

- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version
- gBleInvalidState_c – At least one bond is still active.

bleResult_t Gap_ReadRadioPowerLevel(*gapRadioPowerLevelReadType_t* txReadType, *deviceId_t* deviceId)

Reads the power level of the controller's radio. The response is contained in the gConnEvtTxPowerLevelRead_c connection event when reading connection TX power level, the gAdvTxPowerLevelRead_c generic event when reading the advertising TX power level, or the gConnEvtRssiRead_c connection event when reading the RSSI.

Parameters

- txReadType – **[in]** Advertising or connection Tx power
- deviceId – **[in]** Peer identifier (for connections only, otherwise ignored)

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetTxPowerLevel(uint8_t powerLevel, *bleTransmitPowerChannelType_t* channelType)

Sets the Tx power level on the controller's radio.

Remark

The application should listen for the gTxPowerLevelSetComplete_c generic event.

Remark

This function executes synchronously.

Remark

For QN908x platform this command is not supported by the controller.

Remark

Instead, use RF_SetTxPowerLevel API to set the desired TX power level.

Parameters

- powerLevel – **[in]** Power level as specified in the controller interface.
- channelType – **[in]** The advertising or connection channel type.

Return values

gBleSuccess_c –

bleResult_t Gap_VerifyPrivateResolvableAddress(uint8_t nvmIndex, const *bleDeviceAddress_t* aAddress)

Verifies a Private Resolvable Address with a bonded device's IRK.

Remark

nvmIndex is an integer ranging from 0 to N-1, where N is the number of bonded devices and can be obtained by calling Gap_GetBondedDevicesCount(&N); the application should listen to the gPrivateResolvableAddressVerified_c event.

Parameters

- nvmIndex – **[in]** Index of the device in NVM bonding area whose IRK must be checked.
- aAddress – **[in]** The Private Resolvable Address to be verified.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetRandomAddress(const *bleDeviceAddress_t* aAddress)

Sets a random address into the Controller.

Remark

The application should listen for the gRandomAddressSet_c generic event.

Parameters

- aAddress – **[in]** The Private Resolvable, Private Non-Resolvable, or Static Random Address.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_ReadControllerLocalRPA(const *bleIdentityAddress_t* *pIdAddress)

Reads the device's Local Private Address for a specific peer device from the controller.

Remark

The application should listen for the gControllerLocalRPARead_c generic event.

Parameters

- pIdAddress – **[in]** pointer to the peer identity address the local private address should be retrieved for.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidState_c – The Controller privacy is not enabled.

bleResult_t Gap_SetDefaultPairingParameters(const *gapPairingParameters_t* *pPairingParameters)

Sets the default pairing parameters to be used by automatic pairing procedures.

Remark

When these parameters are set, the Security Manager automatically responds to a Pairing Request or a Peripheral Security Request using these parameters. If NULL is provided, it returns to the default state where all security requests are sent to the application.

Remark

This function executes synchronously.

Parameters

- pPairingParameters – **[in]** Pairing parameters as required by the SMP or NULL.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_UpdateConnectionParameters(*deviceId_t* deviceId, uint16_t intervalMin, uint16_t intervalMax, uint16_t peripheralLatency, uint16_t timeoutMultiplier, uint16_t minCeLength, uint16_t maxCeLength)

Request a set of new connection parameters.

Parameters

- deviceId – **[in]** The DeviceID for which the command is intended
- intervalMin – **[in]** The minimum value for the connection event interval
- intervalMax – **[in]** The maximum value for the connection event interval
- peripheralLatency – **[in]** The peripheral latency parameter
- timeoutMultiplier – **[in]** The connection timeout parameter
- minCeLength – **[in]** The minimum value for the connection event length
- maxCeLength – **[in]** The maximum value for the connection event length

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.

- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

Pre
A connection must be in place

bleResult_t Gap_EnableUpdateConnectionParameters(*deviceId_t* deviceId, bool_t enable)
Update the connection parameters.

Remark

The LE central Host may accept the requested parameters or reject the request

Parameters

- deviceId – **[in]** The DeviceID for which the command is intended
- enable – **[in]** Allow/disallow the parameters update

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – The device id is not valid.

Pre
A connection must be in place

bleResult_t Gap_UpdateLeDataLength(*deviceId_t* deviceId, uint16_t txOctets, uint16_t txTime)
Update the Tx Data Length.

Remark

The response is contained in the gConnEvtLeDataLengthChanged_c connection event.

Parameters

- deviceId – **[in]** The DeviceID for which the command is intended
- txOctets – **[in]** Maximum transmission number of payload octets
- txTime – **[in]** Maximum transmission time

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – The device id is not valid.

Pre
A connection must be in place

bleResult_t Gap_SetDefaultConnectionSubrateParameters(const *gapConnectionSubrateParameters_t* *pConnSubrateParam)

The function sets the initial values of the acceptable parameters for subrating requests, for all future connections where the Controller is Central. User should wait for a gLeSetDefaultConnectionSubrateParametersSetupComplete_c generic event or for a gInternalError_c generic event with source gSetDefaultConnectionSubrateParameters_c .

Parameters

- pConnSubrateParam – **[in]** Pointer to the new set of connection subrate parameters

Return values

bleResult_t – gBleSuccess_c or error.

bleResult_t Gap_ConnectionSubrateRequest(*deviceId_t* deviceId, const *gapConnectionSubrateParameters_t* *pConnSubrateParam)

Requests a set of new connection subrate parameters. A connection must be in place. When initiated on a Central this procedure triggers the Link Layer Connection Subrate Update procedure. When initiated on a Peripheral this procedure triggers the Link Layer Connection Subrate Request procedure. User should wait for a gConnEvtLeSubrateChange_c connection event or for a gInternalError_c generic event with source gConnectionSubrateRequest_c.

Parameters

- deviceId – **[in]** The DeviceID for which the command is intended
- pConnSubrateParam – **[in]** Pointer to the new set of connection subrate parameters

Return values

bleResult_t – gBleSuccess_c or error.

bleResult_t Gap_EnableHostPrivacy(bool_t enable, const uint8_t *aIrk)

Enables or disables Host Privacy (automatic regeneration of a Private Address).

Remark

The application should listen for the gHostPrivacyStateChanged_c generic event.

Parameters

- enable – **[in]** TRUE to enable, FALSE to disable.
- aIrk – **[in]** Local IRK to be used for Resolvable Private Address generation or NULL for Non-Resolvable Private Address generation. Ignored if enable is FALSE.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnableControllerPrivacy(bool_t enable, const uint8_t *aOwnIrk, uint8_t peerIdCount, const *gapIdentityInformation_t* *aPeerIdentities)

Enables or disables Controller Privacy (Enhanced Privacy feature).

Remark

The application should listen for the gControllerPrivacyStateChanged_c generic event.

Parameters

- enable – **[in]** TRUE to enable, FALSE to disable.
- aOwnIrk – **[in]** Local IRK. Ignored if enable is FALSE, otherwise shall not be NULL.
- peerIdCount – **[in]** Size of aPeerIdentities array. Shall not be zero or greater than gcGapControllerResolvingListSize_c. Ignored if enable is FALSE.
- aPeerIdentities – **[in]** Array of peer identity addresses and IRKs. Ignored if enable is FALSE, otherwise shall not be NULL.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleFeatureNotSupported_c – Cannot use Device Privacy mode if controller does not support LE Set Privacy Mode Command.

bleResult_t Gap_SetPrivacyMode(uint8_t nvmIndex, *blePrivacyMode_t* privacyMode)

Sets the privacy mode to an existing bond.

Remark

The change has no effect (other than the change in NVM) unless controller privacy is enabled for the bonded identities.

Parameters

- nvmIndex – **[in]** Index of the device in the NVM bonding area.
- privacyMode – **[in]** Controller privacy mode: Network or Device

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Cannot use Device Privacy mode if controller does not support LE Set Privacy Mode Command.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleUnavailable_c – The bond data entry for this device is corrupted.
- gBleOutOfMemory_c – There is no more room to allocate memory for a bonding entry.

bleResult_t Gap_ControllerTest(*gapControllerTestCmd_t* testCmd, uint8_t radioChannel, uint8_t txDataLength, *gapControllerTestTxType_t* txPayloadType)

Commands a Controller Test procedure.

Remark

The application should listen for the gControllerTestEvent_c generic event.

Remark

This API function is available only in the full-featured host library.

Parameters

- testCmd – Command type - “start TX test”, “start RX test” or “end test”.
- radioChannel – Radio channel index. Valid range: 0-39. Frequency will be F[MHz] = 2402 + 2 * index. Effective range: 2402-2480 MHz. Ignored if command is “end test”.
- txDataLength – Size of packet payload for TX tests. Ignored if command is “start RX test” or “end test”.
- txPayloadType – Type of packet payload for TX tests. Ignored if command is “start RX test” or “end test”.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_ModifySleepClockAccuracy(*gapSleepClockAccuracy_t* action)

Requests the Controller to change its sleep clock accuracy for testing purposes.

Remark

The application should listen for the generic event.

Parameters

- action – Specifies whether the sleep clock should be changed to one that is more accurate or one that is less accurate.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_LeReadPhy(*deviceId_t* deviceId)

Read the Tx and Rx Phy on the connection with a device.

Remark

The application should listen for the gLePhyEvent_c generic event. This API is available only in the Bluetooth 5.0 Host Stack.

Parameters

- deviceId – **[in]** Device ID of the peer.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeSetPhy(bool_t defaultMode, *deviceId_t* deviceId, uint8_t allPhys, uint8_t txPhys, uint8_t rxPhys, uint16_t phyOptions)

Set the Tx and Rx Phy preferences on the connection with a device or all subsequent connections.

Remark

The application should listen for the gLePhyEvent_c generic event. This API is available only in the Bluetooth 5.0 Host Stack.

Parameters

- defaultMode – **[in]** Use the provided values for all subsequent connections
- deviceId – **[in]** Device ID of the peer Ignored if defaultMode is TRUE.
- allPhys – **[in]** Host preferences on Tx and Rx Phy, as defined by gapLeAllPhyFlags_t
- txPhys – **[in]** Host preferences on Tx Phy, as defined by gapLePhyFlags_t, ignored for gLeTxPhyNoPreference_c
- rxPhys – **[in]** Host preferences on Rx Phy, as defined by gapLePhyFlags_t, ignored for gLeRxPhyNoPreference_c
- phyOptions – **[in]** Host preferences on Coded Phy, as defined by gapLePhyOptionsFlags_t Ignored if defaultMode is TRUE.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version

bleResult_t Gap_ControllerEnhancedNotification(uint16_t eventType, *deviceId_t* deviceId)

Configures enhanced notifications on advertising, scanning and connection events on the controller.

Remark

The application should listen for the gControllerNotificationEvent_c generic event.

Remark

This function executes synchronously.

Parameters

- eventType – **[in]** Event type selection as specified by bleNotificationEventType_t.
- deviceId – **[in]** Device ID of the peer, used only for connection events.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory.

bleResult_t Gap_BleAdvIndexChange(*bleAdvIndexType_t* advIndexType, uint8_t aUserDefinedChannels[3])

This function configures the advertising index type.

Parameters

- advIndexType – **[in]** Advertising index type
- aUserDefinedChannels – **[in]** User defined channels array

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_LoadKeys(uint8_t nvmIndex, *gapSmpKeys_t* *pOutKeys, *gapSmpKeyFlags_t* *pOutKeyFlags, bool_t *pOutLeSc, bool_t *pOutAuth)

Retrieves the keys from an existing bond with a device.

Remark

This API requires that the aAddress in the pOutKeys shall not be NULL.

Remark

The application will check pOutKeyFlags to see which information is valid in pOutKeys.

Remark

This function executes synchronously.

Parameters

- nvmIndex – **[in]** Index of the device in the NVM bonding area.
- pOutKeys – **[out]** Pointer to fill the keys distributed during pairing.
- pOutKeyFlags – **[out]** Pointer to indicate which keys were distributed during pairing.
- pOutLeSc – **[out]** Pointer to mark if LE Secure Connections was used during pairing.
- pOutAuth – **[out]** Pointer to mark if the device was authenticated for MITM during pairing.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_SaveKeys(uint8_t nvmIndex, const *gapSmpKeys_t* *pKeys, bool_t leSc, bool_t auth)

Saves the keys to a new or existing bond based on OOB information.

Remark

This API requires that the aAddress in the pKeys shall not be NULL.

Remark

If any of the keys are passed as NULL, they will not be saved.

Remark

The application listen for gBondCreatedEvent_c to confirm the bond was created.

Parameters

- nvmIndex – **[in]** Index of the device in the NVM bonding area.
- pKeys – **[in]** Pointer to the keys distributed during pairing.
- leSc – **[in]** Indicates if LE Secure Connections was used during pairing.
- auth – **[in]** Indicates if the device was authenticated for MITM during pairing.

Return values

- gBleSuccess_c –

- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetChannelMap(const *bleChannelMap_t* channelMap)

Set the channel map in the Controller and trigger an LL channel map update. Specifies the channel map for data, secondary advertising and periodic physical channels.

Remark

The application should listen for the gChannelMapSet_c generic event.

Remark

This function executes synchronously.

Remark

API supported on GAP Central devices or Broadcaster with Extended Advertising support.

Parameters

- channelMap – **[in]** Array with the channels using 0 for bad channels and 1 for unknown.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.

bleResult_t Gap_ReadChannelMap(*deviceId_t* deviceId)

Reads the channel map of a connection.

Remark

The application should listen for the gConnEvtChannelMapRead_c connection event.

Remark

This function executes synchronously.

Parameters

- deviceId – **[in]** Device ID of the peer.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.

- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_SetExtAdvertisingParameters(*gapExtAdvertisingParameters_t* *pAdvertisingParameters)

Sets up the Extended Advertising Parameters.

Remark

GAP Peripheral-only API function.

Parameters

- pAdvertisingParameters – **[in]** Pointer to gapExtAdvertisingParameters_t structure.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gGapAnotherProcedureInProgress_c – Another set extended advertisment parameters command is in progress.

bleResult_t Gap_SetExtAdvertisingData(uint8_t handle, *gapAdvertisingData_t* *pAdvertisingData, *gapScanResponseData_t* *pScanResponseData)

Sets up the Extended Advertising and Extended Scan Response Data.

Remark

Any of the parameters may be NULL, in which case they are ignored. Therefore, this function can be used to set any of the parameters individually or both at once.

Remark

GAP Peripheral-only API function.

Parameters

- handle – **[in]** The ID of the advertising set
- pAdvertisingData – **[in]** Pointer to *gapAdvertisingData_t* structure or NULL.
- pScanResponseData – **[in]** Pointer to gapScanResponseData_t structure or NULL.

Return values

- gBleSuccess_c –

- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – The nvm index of the deviceId is bigger than the number of allowed bonded devices, or the nvm saving operation did not have enough memory.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleInvalidState_c – The advertising set was not configured previously using Gap_SetExtAdvertisingParameters.
- gGapAdvDataTooLong_c – The advertising data is too long.

bleResult_t Gap_SetExtAdvertisingDecisionData(uint8_t handle, const *gapAdvertisingDecisionData_t* *pAdvertisingDecisionData)

Sets up the Extended Advertising Decision Data.

Remark

pDecisionData or pKey in the *gapAdvertisingDecisionData_t* structure may be NULL but not both.

Remark

GAP Peripheral-only API function.

Remark

Application should wait for gExtAdvertisingDecisionDataSetupComplete_c or generic event or for gInternalError_c generic event with errorSource = gSetExtAdvDecisionData_c.

Parameters

- handle – **[in]** The ID of the advertising set
- pAdvertisingDecisionData – **[in]** Pointer to *gapAdvertisingDecisionData_t* structure.

Return values

- gBleFeatureNotSupported_c – in case gLeExtendedAdv_c or gLeDecisionBasedAdvertisingFiltering_c are not supported.
- gBleInvalidParameter_c – in case at least 1 parameter is incorrect.
- gBleOutOfMemory_c – in case the memory allocation for the app to host message fails.
- gBleSuccess_c – otherwise.

bleResult_t Gap_StartExtAdvertising(*gapAdvertisingCallback_t* advertisingCallback, *gapConnectionCallback_t* connectionCallback, uint8_t handle, uint16_t duration, uint8_t maxExtAdvEvents)

Commands the controller to start the extended advertising.

Remark

The advertisingCallback confirms or denies whether the advertising has started. The connectionCallback is only used if a connection gets established during advertising.

Remark

GAP Peripheral-only API function.

Parameters

- advertisingCallback – **[in]** Callback used by the application to receive advertising events. Can be NULL.
- connectionCallback – **[in]** Callback used by the application to receive connection events. Can be NULL.
- handle – **[in]** The ID of the advertising set
- duration – **[in]** The duration of the advertising
- maxExtAdvEvents – **[in]** The maximum number of advertising events

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidState_c – The advertising is already started or pending to be started.

bleResult_t Gap_StopExtAdvertising(uint8_t handle)

Commands the controller to stop extended advertising for set ID.

Remark

GAP Peripheral-only API function.

Parameters

- handle – **[in]** The ID of the advertising set

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.

- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleInvalidState_c – The advertising set is not started.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_RemoveAdvSet(uint8_t handle)

Commands the controller to remove the specified advertising set and all its data.

Remark

GAP Peripheral-only API function.

Parameters

- handle – **[in]** The ID of the advertising set

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetPeriodicAdvParameters(*gapPeriodicAdvParameters_t* *pAdvertisingParameters)

Sets up the Periodic Advertising Parameters.

Remark

GAP Peripheral-only API function.

Parameters

- pAdvertisingParameters – **[in]** Pointer to gapPeriodicAdvParameters_t structure.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetPeriodicAdvSubeventData(uint8_t advHandle, const *gapPeriodicAdvertisingSubeventData_t* *pData)

Sets up the Periodic Advertising Subevent Data.

Remark

GAP Peripheral-only API function.

Parameters

- advHandle – **[in]** Advertising handle.
- gapPeriodicAdvertisingSubeventData_t – Pointer to *gapPeriodicAdvertisingSubeventData_t* structure.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetPeriodicAdvResponseData(uint16_t syncHandle, const *gapPeriodicAdvertisingResponseData_t* *pData)

Sets up the Periodic Advertising Response Data.

Parameters

- syncHandle – **[in]** Sync handle.
- gapPeriodicAdvertisingResponseData_t – Pointer to *gapPeriodicAdvertisingResponseData_t* structure.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetPeriodicSyncSubevent(uint16_t syncHandle, const *gapPeriodicSyncSubeventParameters_t* *pParams)

Instructs the controller to sync with a subset of the subevents within a PAWR train identified by syncHandle.

Parameters

- syncHandle – **[in]** Sync handle.
- gapPeriodicSyncSubeventParameters_t – Pointer to *gapPeriodicSyncSubeventParameters_t* structure.

Return values

- gBleSuccess_c –

- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetPeriodicAdvertisingData(uint8_t handle, *gapAdvertisingData_t* *pAdvertisingData, bool_t bUpdateDID)

Sets up the Periodic Advertising Data.

Remark

GAP Peripheral-only API function.

Parameters

- handle – **[in]** The ID of the periodic advertising set
- pAdvertisingData – **[in]** Pointer to *gapAdvertisingData_t* structure.
- bUpdateDid – **[in]** If TRUE, use operation mode gHciExtDataUnchanged_c.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleInvalidState_c – The advertising set was not previously configured using Gap_SetPeriodicAdvParameters.
- gGapAdvDataTooLong_c – The advertising data is too long.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_StartPeriodicAdvertising(uint8_t handle, bool_t bIncludeADI)

Commands the controller to start periodic advertising for set ID.

Remark

GAP Peripheral-only API function.

Parameters

- handle – **[in]** The ID of the periodic advertising set
- bIncludeADI – **[in]** If TRUE, include ADI field in AUX_SYNC_IND PDUs

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.

- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleInvalidState_c – The advertising set was not previously configured using Gap_SetPeriodicAdvParameters.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_StopPeriodicAdvertising(uint8_t handle)

Commands the controller to stop periodic advertising for set ID.

Remark

GAP Peripheral-only API function.

Parameters

- handle – **[in]** The ID of the periodic advertising set

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleInvalidState_c – The advertising set was not previously configured using Gap_SetPeriodicAdvParameters.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_UpdatePeriodicAdvList(*gapPeriodicAdvListOperation_t* operation, *bleAddressType_t* addrType, uint8_t *pAddr, uint8_t SID)

Manage the periodic advertising list.

Remark

GAP Central-only API function.

Parameters

- operation – **[in]** The list operation: add/remove a device, or clear all.
- addrType – **[in]** The address type of the periodic advertiser.
- pAddr – **[in]** Pointer to the advertiser's address.
- SID – **[in]** The ID of the advertising set.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

- gGapAnotherProcedureInProgress_c – Periodic advertising create sync is in progress.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_PeriodicAdvCreateSync(*gapPeriodicAdvSyncReq_t* *pReq)

Start tracking periodic advertisements. Scanning is required to be ON for this request to be processed, so the scanning callback will receive the periodic advertising events.

Remark

GAP Central-only API function.

Parameters

- pReq – **[in]** Pointer to the Sync Request parameters.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gGapAnotherProcedureInProgress_c – Periodic advertising create sync is in progress.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_PeriodicAdvTerminateSync(uint16_t syncHandle)

Stop tracking periodic advertisements.

Remark

GAP Central-only API function.

Parameters

- syncHandle – **[in]** Used to identify the periodic advertiser

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gGapAnotherProcedureInProgress_c – Periodic advertising create sync is in progress.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_PeriodicAdvReceiveEnable(uint16_t syncHandle, bool_t enableDuplicateFiltering)

Enable Periodic Advertisement Sync Transfer Controller feature.

Parameters

- syncHandle – **[in]** Used to identify the periodic advertiser
- enableDuplicateFiltering – **[in]** Used to enable or disable duplicate filtering

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_PeriodicAdvReceiveDisable(uint16_t syncHandle)

Disable Periodic Advertisement Sync Transfer Controller feature.

Parameters

- syncHandle – **[in]** Used to identify the periodic advertiser

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_PeriodicAdvSyncTransfer(*gapPeriodicAdvSyncTransfer_t* *pParam)

Instruct the Controller to send synchronization information about the periodic advertising train identified by the sync handle to a connected device.

Parameters

- pParam – **[in]** Pointer to the command arguments

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_PeriodicAdvSetInfoTransfer(*gapPeriodicAdvSetInfoTransfer_t* *pParam)

Instruct the Controller to send synchronization information about the periodic advertising to a connected device.

Parameters

- pParam – **[in]** Pointer to the command arguments

Return values

- gBleSuccess_c –

- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetPeriodicAdvSyncTransferParams(*gapSetPeriodicAdvSyncTransferParams_t* *pParam)

Specify how the Controller will process periodic advertising synchronization information received from the device identified by the device id.

Parameters

- pParam – **[in]** Pointer to the command arguments

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetDefaultPeriodicAdvSyncTransferParams(*gapSetPeriodicAdvSyncTransferParams_t* *pParam)

Specify the initial value for the mode, skip, timeout, and Constant Tone Extension type (set by the Gap_SetPeriodicAdvSyncTransferParams command) to be used for all subsequent connections over the LE transport.

Parameters

- pParam – **[in]** Pointer to the command arguments

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_ResumeLeScStateMachine(computeDhKeyParam_t *pData)

Resume the pairing process. At this point the ECDH key must be computed. This function should be called only for secured LE connections. In any other cases the user should make his own code for handling the case when the ECDH computation is completed.

Parameters

- pData – **[in]** Pointer to the data used to resume the host state machine. The data is allocated by the stack when it requests an ECDH multiplication. It is also freed by the stack at the end of the multiplication.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_SetConnectionlessCteTransmitParameters(*gapConnectionlessCteTransmitParams_t* *pTransmitParams)

Set Connectionless CTE Transmit Parameters for an advertising set.

Parameters

- pTransmitParams – **[in]** Pointer to struct containing parameters.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnableConnectionlessCteTransmit(uint8_t handle, *bleCteTransmitEnable_t* enable)

Enable or disable Connectionless CTE Transmit for an advertising set.

Parameters

- handle – **[in]** Advertising set handle.
- enable – **[in]** Enable or disable CTE Transmit.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnableConnectionlessIqSampling(uint16_t syncHandle, *gapConnectionlessIqSamplingParams_t* *pIqSamplingParams)

Enable or disable Connectionless IQ sampling for an advertising train.

Parameters

- syncHandle – **[in]** Used to identify advertising train.
- pIqSamplingParams – **[in]** Pointer to struct containing parameters.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetConnectionCteReceiveParameters(*deviceId_t* deviceId, *gapConnectionCteReceiveParams_t* *pReceiveParams)

Set CTE Receive Parameters for a certain connection.

Parameters

- deviceId – **[in]** Peer device ID.
- pReceiveParams – **[in]** Pointer to struct containing parameters.

Return values

- gBleSuccess_c –

- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetConnectionCteTransmitParameters(*deviceId_t* deviceId, *gapConnectionCteTransmitParams_t* *pTransmitParams)

Set CTE Transmit Parameters for a certain connection.

Parameters

- deviceId – **[in]** Peer device ID.
- pTransmitParams – **[in]** Pointer to struct containing parameters.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnableConnectionCteRequest(*deviceId_t* deviceId, *gapConnectionCteReqEnableParams_t* *pCteReqEnableParams)

Enable or disable CTE Request procedure for a certain connection.

Parameters

- deviceId – **[in]** Peer device ID.
- pCteReqEnableParams – **[in]** Pointer to struct containing parameters.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnableConnectionCteResponse(*deviceId_t* deviceId, *bleCteRspEnable_t* enable)

Enable or disable sending CTE Responses for a certain connection.

Parameters

- deviceId – **[in]** Peer device ID.
- enable – **[in]** Enable or disable sending CTE Responses.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_ReadAntennaInformation(void)

Read Antenna Information.

Remark

Antenna information contained in gAntennaInformationRead_c generic event.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnhancedReadTransmitPowerLevel(*deviceId_t* deviceId, *blePowerControlPhyType_t* phy)

Read local current and maximum tx power levels for a certain connection and PHY.

Parameters

- deviceId – **[in]** Peer device ID.
- phy – **[in]** PHY.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_ReadRemoteTransmitPowerLevel(*deviceId_t* deviceId, *blePowerControlPhyType_t* phy)

Read remote tx power for a certain connection and PHY.

Parameters

- deviceId – **[in]** Peer device ID.
- phy – **[in]** PHY.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_SetPathLossReportingParameters(*deviceId_t* deviceId, *gapPathLossReportingParams_t* *pPathLossReportingParams)

Set path loss threshold reporting parameters for a certain connection.

Parameters

- deviceId – **[in]** Peer device ID.
- pPathLossReportingParams – **[in]** Pointer to struct containing parameters.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnablePathLossReporting(*deviceId_t* deviceId, *blePathLossReportingEnable_t* enable)

Enable or disable path loss threshold reporting for a certain connection.

Parameters

- deviceId – **[in]** Peer device ID.
- enable – **[in]** Enable or disable path loss threshold reporting.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EnableTransmitPowerReporting(*deviceId_t* deviceId, *bleTxPowerReportingEnable_t* localEnable, *bleTxPowerReportingEnable_t* remoteEnable)

Enable or disable tx power reporting for a certain connection.

Parameters

- deviceId – **[in]** Peer device ID.
- localEnable – **[in]** Enable or disable local tx power reports.
- removeEnable – **[in]** Enable or disable remote tx power reports.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_GenerateDhKeyV2(ecdhPublicKey_t *pRemoteP256PublicKey, *gapPrivateKeyType_t* keyType)

Initiates generation of a Diffie-Hellman key in the Controller for use over the LE transport. Version 2 of LE Generate DHKey command.

Remark

Generated key is contained in gHciLeGenerateDhKeyCompleteEvent_c event.

Parameters

- pRemoteP256PublicKey – **[in]** Pointer to the remote P-256 public key used as input for DH key generation.
- keyType – **[in]** The private key used of DH key generation.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EattConnectionRequest(*deviceId_t* deviceId, uint16_t mtu, uint8_t cBearers, uint16_t initialCredits, bool_t autoCreditsMgmt)

Open up to 5 Enhanced ATT bearers.

Parameters

- deviceId – **[in]** Peer device id
- mtu – **[in]** MTU
- cBearers – **[in]** Number of bearers
- initialCredits – **[in]** Initial credits
- autoCreditsMgmt – **[in]** EATT will automatically send credits in chunks of initialCredits if TRUE.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EattConnectionAccept(*deviceId_t* deviceId, bool_t accept, uint16_t localMtu, uint16_t initialCredits, bool_t autoCreditsMgmt)

Accept or reject a received EATT Connection Request.

Parameters

- deviceId – **[in]** Peer device id
- accept – **[in]** TRUE - accept received EattConnectionRequest FALSE - reject incoming EattConnectionRequest
- localMtu – **[in]** Local MTU
- Initial (initialCredits,) – **[in]** credits
- autoCreditsMgmt – **[in]** EATT will automatically send credits in chunks of initialCredits if TRUE.

Return values

- gBleSuccess_c –

- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EattReconfigureRequest(*deviceId_t* deviceId, uint16_t mtu, uint16_t mps, uint8_t cBearers, *bearerId_t* *pBearers)

Reconfigure the MTU of up to 5 Enhanced ATT bearers.

Parameters

- deviceId – **[in]** Peer device id
- mtu – **[in]** New MTU value to be configured.
- mps – **[in]** New MPS value to be configured. Set to 0 to use current maximum mps value of the channels being reconfigured
- cBearers – **[in]** Number of bearers
- *pBearers – **[in]** Initial credits

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EattSendCredits(*deviceId_t* deviceId, *bearerId_t* bearerId, uint16_t credits)

Send L2cap credits for Enhanced ATT bearers.

Parameters

- deviceId – **[in]** Peer device id
- bearerId – **[in]** Enhanced ATT bearer id.
- credits – **[in]** Number of credits.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EattDisconnect(*deviceId_t* deviceId, *bearerId_t* bearerId)

Disconnect the specified bearer.

Parameters

- deviceId – **[in]** Peer device id
- bearerId – **[in]** Enhanced ATT bearer id to be disconnected.

Return values

- gBleSuccess_c –

- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_GetDeviceIdFromConnHandle(uint16_t connHandle, *deviceId_t* *pDeviceId)

Returns the deviceId associated with the received connection handle.

Parameters

- connHandle – **[in]** Connection identifier
- pDeviceId – **[out]** Corresponding device id

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_GetConnectionHandleFromDeviceId(*deviceId_t* deviceId, uint16_t *pConnHandle)

Returns the deviceId associated with the received connection handle.

Parameters

- deviceId – **[in]** Connection identifier
- pConnHandle – **[out]** Corresponding connection handle

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_GetHostVersion(*gapHostVersion_t* *pOutHostVersion)

Retrieves Host Version information.

Parameters

- pOutHostVersion – **[out]** Pointer to the memory location where the Host Version information should be stored.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.

bleResult_t Gap_ReadRemoteVersionInformation(*deviceId_t* deviceId)

Reads the version information of a peer device.

Parameters

- deviceId – **[in]** Peer device identifier.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_GetConnParamsMonitoring(*deviceId_t* deviceId, uint8_t mode)

Get the Connection parameters for the given deviceId in the given mode.

Parameters

- deviceId – **[in]** Peer device Id.
- mode – **[in]** Connection parameters event report mode: bit 0: update the local sequence number for central / peripheral differentiation and send the LE_Handover_Connection_Parameters_Update_Event after remote sequence number change. bit 1: Send LE_Handover_Connection_Parameters_Update_Event when the connection parameters are updated following an LL procedure

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeChannelOverride(*bleChannelOverrideMode_t* mode, uint8_t channelListLength, uint8_t *pChannelList)

This function sets the channels to be used for advertising, scanning or initiation.

If the mode is 0x00 (advertising), the specified channels are used by the following advertising commands. The channels used by the ongoing advertising will not change until the advertising is disabled, even if a new channel override command with mode 0x00 is received. This allows different advertising channels for different advertising sets. The mode 0x00 (advertising) can be issued when an advertising is ongoing. The setting will be used by the next advertising enable command.

Remark

In the channel list, the MSB of each byte indicates if the channel is BLE channel index or generic channel index:

- BLE channel index: 0 to 39
- Generic channel index: 0x80+0 to 0x80+127

If the mode is 0x01 or 0x02 (scan or initiation), the specified channels are used by the following scan and initiation. The command with mode 0x01 or 0x02 should be issued when the scan or initiation is not ongoing.

When a generic channel is used, the whitening is initialized by the lower 6 bits of the generic channel index. When a BLE channel is used, the whitening is initialized by the BLE channel index. So the BLE channel 37/38/39 are not strictly the same as the generic channels 42/66/120: they operate on the same frequency but their channel whitening is different.

Parameters

- mode – **[in]** Override the advertising, scanning or initiation channels.
- channelListLength – **[in]** Length of channel list, must be between 1 and 6.
- pChannelList – **[in]** List of channels (see remarks for more details).

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – One or more parameters are invalid.

- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeSetSchedulerPriority(uint16_t priorityHandle)

This function sets the priority for one connection in case of several connections by calling the corresponding HCI command.

Parameters

- priorityHandle – **[in]** Parameter that sets the priority for connections

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LePeriodicAdvUpdateSync(uint16_t syncHandle, uint16_t skip, uint16_t syncTimeout)

This function updates the synchronization parameters for periodic advertising.

Parameters

- syncHandle – **[in]** Handle identifying the periodic advertising sync.
- skip – **[in]** Number of periodic advertising packets to skip.
- syncTimeout – **[in]** Synchronization timeout value.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeSetLocalPeripheralLatencyEnable(*deviceId_t* deviceId, bool_t enable)

This function enables or disables local Peripheral latency for a connection.

Parameters

- deviceId – **[in]** Handle identifying the connection.
- enable – **[in]** FALSE to disable, TRUE to enable local Peripheral latency.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_LeSetHostFeature(uint8_t bitNumber, bool_t enable)

This function is used by the Host to set or clear a bit controlled by the Host in the Link Layer FeatureSet.

Parameters

- bitNumber – **[in]** Bit position in the FeatureSet
- enable – **[in]** Host feature is enabled/disabled

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

bleResult_t Gap_EncryptAdvertisingData(const *gapAdvertisingData_t* *pAdvertisingData, const uint8_t *pKey, const uint8_t *pIV, uint8_t *pOutput)

This function is used to encrypt a series of AD structures into an encrypted AD structure.

Parameters

- pAdvertisingData – **[in]** Pointer to AD(s) to be encrypted.

- pKey – **[in]** Pointer to 16-byte key to be used for encryption (must be big endian).
- pIV – **[in]** Pointer to 8-byte initialization vector (must be little endian).
- pOutput – **[out]** Pointer for location of output encrypted data. Must be large enough to accommodate the size of the total data to be encrypted plus the size of the Randomizer and MIC fields.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – At least one of the provided parameters is invalid.
- gBleOutOfMemory_c – Could not allocate memory for the buffers used in CCM.
- gBleRngError_c – Could not generate the randomizer.
- gBleSecLibError_c – CCM call failed.

bleResult_t Gap_DecryptAdvertisingData(uint8_t *pData, uint16_t dataLength, const uint8_t *pKey, const uint8_t *pIV, uint8_t *pOutput)

This function is used to decrypt advertising data.

Parameters

- pData – **[in]** Pointer to encrypted data (AD payload).
- dataLength – **[in]** Length of the encrypted data (includes randomizer and MIC fields).
- pKey – **[in]** Pointer to 16-byte key to be used for decryption (must be big endian).
- pIV – **[in]** Pointer to 8-byte initialization vector (must be little endian).
- pOutput – **[out]** Pointer to the location of decrypted data.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – At least one of the provided parameters is invalid.
- gBleOutOfMemory_c – Could not allocate memory for the buffers used in CCM.
- gBleSecLibError_c – CCM call failed.

void Gap_SetConnectionCallback(*gapConnectionCallback_t* pfConnectionCallback)

Set the GAP connection callback.

Parameters

- pfConnectionCallback – **[in]** The function called when one of the events defined in gapConnectionEventType_t occurs.

Returns

none

void Gap_SetScanningCallback(*gapScanningCallback_t* pfScanningCallback)

Set the GAP scanning callback.

Parameters

- pfScanningCallback – **[in]** The function called when one of the events defined in gapScanningEventType_t occurs.

Returns
none

Gap_AddSecurityModesAndLevels(modeLevelA, modeLevelB)

Macro used to combine two security mode-levels.

Remark

This macro is useful when two different security requirements must be satisfied at the same time, such as a device central security requirement and a service-specific security requirement.

Parameters

- modeLevelB (modeLevelA,) – **[in]** The two security mode-levels.

Returns
The resulting security mode-level.

Gap_CancelInitiatingConnection()

Macro used to cancel a connection initiated by Gap_Connect(...).

Remark

This macro can only be used for a connection that has not yet been established, such as the "gConnEvtConnected_c" has not been received. For example, call this when a connection request has timed out. Application should listen for gCreateConnectionCanceled_c generic event.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – The requested feature is not supported by this stack version.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

Gap_ReadAdvertisingTxPowerLevel()

Macro used to read the radio transmitter power when advertising.

Remark

The result is contained in the gAdvTxPowerLevelRead_c generic event.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

Gap_ReadRssi(deviceId)

Macro used to read the RSSI of a radio connection.

Remark

The result is contained in the gConnEvtRssiRead_c connection event. The RSSI value is a signed byte, and the unit is dBm. If the RSSI cannot be read, the gConnEvtPowerReadFailure_c connection event is generated.

Parameters

- deviceId – **[in]** Device ID identifying the radio connection.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

Gap_ReadTxPowerLevelInConnection(deviceId)

Macro used to read the radio transmitting power level of a radio connection.

Remark

The result is contained in the gConnEvtTxPowerLevelRead_c connection event. If the TX Power cannot be read, the gConnEvtPowerReadFailure_c connection event is generated.

Parameters

- deviceId – **[in]** Device ID identifying the radio connection.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

Gap_GetConnParams(deviceId)

Get the Connection parameters for the given deviceId.

Parameters

- deviceId – **[in]** Peer device Id.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – A parameter has an invalid value or is outside the accepted range.
- gBleOutOfMemory_c – Cannot allocate memory for the Host task.

gCancelOngoingInitiatingConnection_d

Use this value as a parameter to the Gap_Disconnect(deviceId) function to cancel any ongoing connection initiation, for example if the connection has timed out.

gMode_2_Mask_d

Mask to check if a Security Mode-and-Level is Mode 2

getSecurityLevel(modeLevel)

Extracts the security level (see gapSecurityLevel_t) from the combined security mode-level (gapSecurityModeAndLevel_t).

getSecurityMode(modeLevel)

Extracts the security mode (see gapSecurityMode_t) from the combined security mode-level (gapSecurityModeAndLevel_t).

isMode_2(modeLevel)

isMode_1(modeLevel)

isSameMode(modeLevelA, modeLevelB)

addSameSecurityModes(modeLevelA, modeLevelB)

addMode1AndMode2(mode1, mode2)

addDifferentSecurityModes(modeLevelA, modeLevelB)

gDefaultEncryptionKeySize_d

The default (minimum) value for the LTK size

gMaxEncryptionKeySize_d

The maximum value for the LTK size

gGapDefaultDeviceSecurity_d

The default value for the Device Security (no requirements)

gGapDefaultSecurityRequirements_d

The default value for a Security Requirement

gGapAdvertisingIntervalRangeMinimum_c

Minimum advertising interval (20 ms)

gGapAdvertisingIntervalDefault_c

Default advertising interval (1.28 s)

gGapAdvertisingIntervalRangeMaximum_c

Maximum advertising interval (10.24 s)

gGapExtAdvertisingIntervalRangeMinimum_c

Minimum extended advertising interval (20 ms)

gGapExtAdvertisingIntervalDefault_c

Default extended advertising interval (1.28 s)

gGapExtAdvertisingIntervalRangeMaximum_c

Maximum extended advertising interval (10485.76 s)

gGapPeriodicAdvIntervalRangeMinimum_c
: Minimum periodic advertising interval (7.5 ms)

gGapPeriodicAdvIntervalDefault_c
: Default periodic advertising interval (2.56 s)

gGapPeriodicAdvIntervalRangeMaximum_c
: Maximum periodic advertising interval (81.91875 s)

gGapAdvertisingChannelMapDefault_c
: Default Advertising Channel Map - all 3 channels are enabled

gGapDefaultAdvertisingParameters_d
: Default value for Advertising Parameters struct

gGapDefaultExtAdvertisingParameters_d
: Default value for Extended Advertising Parameters struct

gGapDefaultPeriodicAdvParameters_d
: Default value for Periodic Advertising Parameters struct

gGapScanIntervalMin_d
: Minimum scan interval (2.5 ms)

gGapScanIntervalDefault_d
: Default scan interval (10 ms)

gGapScanIntervalMax_d
: Maximum scan interval (10.24 s)

gGapScanWindowMin_d
: Minimum scan window (2.5 ms)

gGapScanWindowDefault_d
: Default scan window (10 ms)

gGapScanWindowMax_d
: Maximum scan window (10.24 s)

gGapRssiMin_d
: Minimum valid value for RSSI (dB)

gGapRssiMax_d
: Maximum valid value for RSSI (dB)

gGapRssiNotAvailable_d
: A special invalid value for the RSSI indicating that the measurement is not available.

gGapScanContinuously_d
: Default value for Scanning duration - Scan continuously until explicitly disable

gGapScanPeriodicDisabled_d
: Default value for Scanning period - Periodic scanning disabled

gGapDefaultScanningParameters_d
: Default value for Scanning Parameters struct

gGapConnIntervalMin_d
: Minimum connection interval (7.5 ms)

gGapConnIntervalMax_d
: Maximum connection interval (4 s)

gGapConnLatencyMin_d
: Minimum connection latency value (0 - no connection event may be ignored)

gGapConnLatencyMax_d
: Maximum connection latency value (499 connection events may be ignored)

gGapConnSuperTimeoutMin_d
: Minimum supervision timeout (100 ms)

gGapConnSuperTimeoutMax_d
: Maximum supervision timeout (32 s)

gGapConnEventLengthMin_d
: Minimum value of the connection event length (0 ms)

gGapConnEventLengthMax_d
: Maximum value of the connection event length (~41 s)

gGapDefaultConnectionLatency_d
: Default connection latency: 0

gGapDefaultSupervisionTimeout_d
: Default supervision timeout: 10s

gGapDefaultMinConnectionInterval_d
: Default minimum connection interval: 100ms

gGapDefaultMaxConnectionInterval_d
: Default maximum connection interval: 200ms

gGapDefaultConnectionRequestParameters_d
: The default value for the Connection Request Parameters structure

gGapChSelAlgorithmNo2

“Channel Selection Algorithm #2 is used” value in LE Channel Selection Algorithm Event

gBlePeriodicAdvOngoingSyncCancelHandle

Sync handle value for which to call the create sync cancel command instead of terminate sync

gGapInvalidSyncHandle

Sync handle used to differentiate extended advertising reports from periodic advertising reports

gNone_c

Values of the AD Flags advertising data structure. No information.

gLeLimitedDiscoverableMode_c

This device is in Limited Discoverable mode.

gLeGeneralDiscoverableMode_c

This device is in General Discoverable mode.

gBrEdrNotSupported_c

This device supports only Bluetooth Low Energy; no support for Classic Bluetooth.

gSimultaneousLeBrEdrCapableController_c

This device’s Controller also supports Classic Bluetooth.

gSimultaneousLeBrEdrCapableHost_c

This device’s Host also supports Classic Bluetooth.

gNoKeys_c

Flags indicating the Keys to be exchanged by the SMP during the key exchange phase of pairing. No key can be distributed.

gLtk_c

Long Term Key.

gIrk_c

Identity Resolving Key.

gCsrk_c

Connection Signature Resolving Key. Deprecated. Not used.

gSecurityMode_1_c

LE Security Mode values for gapSecurityMode_t Mode 1 - Encryption required (except for Level 1).

gSecurityMode_2_c

Mode 2 - Deprecated. Not used.

gSecurityLevel_NoSecurity_c

LE Security Level values for gapSecurityLevel_t No security (combined only with Mode 1).

gSecurityLevel_NoMitmProtection_c

Unauthenticated (no MITM protection).

gSecurityLevel_WithMitmProtection_c

Authenticated (MITM protection by PIN or OOB).

gSecurityLevel_LeSecureConnections_c

Authenticated with LE Secure Connections.

gSecurityMode_1_Level_1_c

Security Mode-and-Level definitions values for gapSecurityModeAndLevel_t Mode 1 Level 1 - No Security.

gSecurityMode_1_Level_2_c

Mode 1 Level 2 - Encryption without authentication.

gSecurityMode_1_Level_3_c

Mode 1 Level 3 - Encryption with authentication.

gSecurityMode_1_Level_4_c

Mode 1 Level 4 - Encryption with LE Secure Connections pairing.

gSecurityMode_2_Level_1_c

Mode 2 Level 1 - Deprecated. Not used.

gSecurityMode_2_Level_2_c

Mode 2 Level 2 - Deprecated. Not used.

gOobNotAvailable_c

Reason for rejecting the pairing request used by gapAuthenticationRejectReason_t. These values are equal to the corresponding reasons from SMP. This device does not have the required OOB for authenticated pairing.

gIncompatibleIoCapabilities_c

The combination of I/O capabilities does not allow pairing with the desired level of security.

gPairingNotSupported_c

This device does not support pairing.

gLowEncryptionKeySize_c

The peer's encryption key size is too low for this device's required security level.

gUnspecifiedReason_c

The host has rejected the pairing for an unknown reason.

gRepeatedAttempts_c

This device is the target of repeated unsuccessful pairing attempts and does not allow further pairing attempts at the moment.

gLinkEncryptionFailed_c

Link could not be encrypted. This reason may not be used by Gap_RejectPairing!

gIoDisplayOnly_c

I/O Capabilities as defined by the SMP used by gapIoCapabilities_t May display a PIN, no input.

gIoDisplayYesNo_c

May display a PIN and has a binary input (e.g., YES and NO buttons).

gIoKeyboardOnly_c

Has keyboard input, no display.

gIoNone_c

No input and no display.

gIoKeyboardDisplay_c

Has keyboard input and display.

gGapCteMinLength_c

AoA/AoD Min CTE length in 8 us units.

gGapCteMaxLength_c

Max CTE length in 8 us units.

gGapCteMinCount_c

Min number of CTEs to transmit in each periodic advertising interval.

gGapCteMaxCount_c

Max number of CTEs to transmit in each periodic advertising interval.

gGapMinSwitchingPatternLength_c

Min number of antennae in the pattern.

gGapMaxSwitchingPatternLength_c

Max number of antennae in the pattern.

gGapEattMaxBearers

Maximum number of bearer Ids in one GAP request/response.

gbmpDIAM_NonConnectableNonScannableUndirected_c

gbmpDIAM_ConnectableUndirected_c

gbmpDIAM_ScannableUndirected_c

struct gapSmpKeys_t

#include <gap_types.h> Structure containing the SMP information exchanged during pairing.

Public Members

uint8_t cLtkSize

Encryption Key Size. If aLtk is NULL, this is ignored.

uint8_t *aLtk

Long Term (Encryption) Key. NULL if LTK is not distributed, else size is given by cLtkSize.

uint8_t *aIrk

Identity Resolving Key. NULL if aIrk is not distributed.

uint8_t *aCsrk

Deprecated - not used.

uint8_t cRandSize

Size of RAND; usually equal to gcMaxRandSize_d. If aLtk is NULL, this is ignored.

uint8_t *aRand

RAND value used to identify the LTK. If aLtk is NULL, this is ignored.

uint16_t ediv

EDIV value used to identify the LTK. If aLtk is NULL, this is ignored.

bleAddressType_t addressType

Public or Random address. If aAddress is NULL, this is ignored.

uint8_t *aAddress

Device Address. NULL if address is not distributed. If aIrk is NULL, this is ignored.

struct gapSecurityRequirements_t

#include <gap_types.h> Security Requirements structure for a Device, a Service or a Characteristic

Public Members

gapSecurityModeAndLevel_t securityModeLevel

Security mode and level.

bool_t authorization

Authorization required.

uint16_t minimumEncryptionKeySize

Minimum encryption key (LTK) size. Ignored if gSecurityMode_1_Level_4_c is required (set to gMaxEncryptionKeySize_d automatically)

struct gapServiceSecurityRequirements_t

#include <gap_types.h> Service Security Requirements

Public Members

uint16_t serviceHandle

Handle of the Service declaration in the GATT Database.

gapSecurityRequirements_t requirements

Requirements for all attributes in this service.

struct gapDeviceSecurityRequirements_t

#include <gap_types.h> Device Security - Security Requirements + Service Security Requirements

Public Members

gapSecurityRequirements_t *pSecurityRequirements

Security requirements added to all services.

uint8_t cNumServices

Number of service-specific requirements; must be less than or equal to gcGapMaxServiceSpecificSecurityRequirements_c.

gapServiceSecurityRequirements_t *aServiceSecurityRequirements

Array of service-specific requirements.

struct gapHandleList_t

#include <gap_types.h> List of Attribute Handles for authorization lists.

Public Members

uint8_t cNumHandles

Number of handles in this list.

uint16_t aHandles[(1U)]

List of handles.

struct gapConnectionSecurityInformation_t

#include <gap_types.h> Connection Security Information structure

Public Members

bool_t authenticated

TRUE if pairing was performed with MITM protection.

gapHandleList_t authorizedToRead

List of handles the peer has been authorized to read.

gapHandleList_t authorizedToWrite

List of handles the peer has been authorized to write.

struct gapPairingParameters_t

#include <gap_types.h> Pairing parameters structure for the Gap_Pair and Gap_AcceptPairingRequest APIs

Public Members

bool_t withBonding

TRUE if this device is able to and wants to bond after pairing, FALSE otherwise.

gapSecurityModeAndLevel_t securityModeAndLevel

The desired security mode-level.

uint8_t maxEncryptionKeySize

Maximum LTK size supported by the device.

gapIoCapabilities_t localIoCapabilities

I/O capabilities used to determine the pairing method.

bool_t oobAvailable

TRUE if this device has Out-of-Band data that can be used for authenticated pairing. FALSE otherwise.

gapSmpKeyFlags_t centralKeys

Indicates the SMP keys to be distributed by the Central.

gapSmpKeyFlags_t peripheralKeys

Indicates the SMP keys to be distributed by the Peripheral.

bool_t leSecureConnectionSupported

Indicates if device supports LE Secure Connections pairing. Conflict if this is FALSE and securityModeAndLevel is gSecurityMode_1_Level_4_c.

bool_t useKeypressNotifications

Indicates if device supports Keypress Notification PDUs during Passkey Entry pairing. Conflict if this is TRUE and localIoCapabilities is set to gIoNone_c.

struct gapPeripheralSecurityRequestParameters_t

#include <gap_types.h> Parameters of a Peripheral Security Request.

Public Members

bool_t bondAfterPairing

TRUE if the Peripheral supports bonding.

bool_t authenticationRequired

TRUE if the Peripheral requires authentication for MITM protection.

struct gapAdvertisingParameters_t

#include <gap_types.h> Advertising Parameters; for defaults see gGapDefaultAdvertisingParameters_d.

Public Members

uint16_t minInterval

Minimum desired advertising interval. Default: 1.28 s.

uint16_t maxInterval

Maximum desired advertising interval. Default: 1.28 s.

bleAdvertisingType_t advertisingType

Advertising type. Default: connectable undirected.

bleAddressType_t ownAddressType

Indicates whether the advertising address is the public address (BD_ADDR) or the random address (set by Gap_SetRandomAddress). Default: public address. If Controller Privacy is enabled, this parameter is irrelevant as Private Resolvable Addresses are always used.

bleAddressType_t peerAddressType

Address type of the peer; only used in directed advertising and Enhanced Privacy.

bleDeviceAddress_t peerAddress

Address of the peer; same as above.

gapAdvertisingChannelMapFlags_t channelMap

Bit mask indicating which of the three advertising channels are used. Default: all three.

gapAdvertisingFilterPolicy_t filterPolicy

Indicates whether the connect and scan requests are filtered using the Filter Accept List. Default: does not use Filter Accept List (process all).

struct gapExtAdvertisingParameters_tag

#include <gap_types.h> Extended Advertising Parameters; for defaults see gGapDefaultExtAdvertisingParameters_d.

Public Members

uint8_t SID

ID of the advertising set chosen by application. Shall be lower than gBleExtAdvMaxSetId_c

uint8_t handle

ID of the advertising set handled by controller. Shall be lower than gNumOfSupportedAdvSets

uint32_t minInterval

Minimum desired advertising interval. Shall be at least equal or higher than gGapExtAdvertisingIntervalRangeMinimum_c

uint32_t maxInterval

Maximum desired advertising interval. Shall be higher than gGapExtAdvertisingIntervalRangeMinimum_c and higher than minInterval

bleAddressType_t ownAddressType

Indicates whether the advertising address is the public address (BD_ADDR) or the random address (set by Gap_SetRandomAddress). Default: public address. If Controller Privacy is enabled, this parameter is irrelevant as Private Resolvable Addresses are always used.

bleDeviceAddress_t ownRandomAddr

The random address used for advertising on the current handle

bleAddressType_t peerAddressType

Address type of the peer; only used in directed advertising and Enhanced Privacy.

bleDeviceAddress_t peerAddress

Address of the peer; same as above.

gapAdvertisingChannelMapFlags_t channelMap

Bit mask indicating which of the three advertising channels are used for primary advertising

gapAdvertisingFilterPolicy_t filterPolicy

Indicates whether the connect and scan requests are filtered using the Filter Accept List

bleAdvRequestProperties_t extAdvProperties

Type of advertising event

int8_t txPower

The maximum power level at which the adv packets are to be transmitted. The Controller shall choose a power level lower than or equal to the one specified by the Host. Valid range: -127 to 20

gapLePhyMode_t primaryPHY

The PHY on which the advertising packets are transmitted (1M or Coded PHY). Used for sending ADV_EXT_IND

gapLePhyMode_t secondaryPHY

The PHY used for sending AUX_ADV_IND PDU. Used only for Extended Advertising Events

uint8_t secondaryAdvMaxSkip

Maximum number of advertising events that can be skipped before the AUX_ADV_IND can be sent

bool_t enableScanReqNotification

Indicates whether the Controller shall send notifications upon the receipt of a scan request PDU

gapLePhyOptionsFlags_t primaryAdvPhyOptions

Preferred or required coding when transmitting on the primary LE Coded PHY

gapLePhyOptionsFlags_t secondaryAdvPhyOptions

Preferred or required coding when transmitting on the secondary LE Coded PHY

struct gapPeriodicAdvParameters_tag

#include <gap_types.h> Periodic Advertising Parameters [v2]; for defaults see gGapDefaultPeriodicAdvParameters_d.

Public Members

uint8_t handle

ID of the advertising set handled by controller. Shall be lower than gNumOfSupportedAdvSets

bool_t addTxPowerInAdv

Set this option to include the Tx power in advertising packet.

uint16_t minInterval

Minimum advertising interval for periodic advertising.

uint16_t maxInterval

Maximum advertising interval for periodic advertising. Should be different and higher than minInterval.

uint8_t numSubevents

Number of subevents.

uint8_t subeventInterval

Interval between subevents.

uint8_t responseSlotDelay
: Time between the advertising packet in a subevent and the first response slot.

uint8_t responseSlotSpacing
: Time between response slots.

uint8_t numResponseSlots
: Number of response slots.

struct gapPeriodicAdvSyncTransfer_tag
: *#include <gap_types.h>*

Public Members

deviceId_t deviceId
: Connection identifier

uint16_t serviceData
: Value provided by the host

uint16_t syncHandle
: Identifier for the periodic advertising train

struct gapPeriodicAdvSetInfoTransfer_tag
: *#include <gap_types.h>*

Public Members

deviceId_t deviceId
: Connection identifier

uint16_t serviceData
: Value provided by the host

uint16_t advHandle
: Identifier for the advertising set

struct gapSetPeriodicAdvSyncTransferParams_tag
: *#include <gap_types.h>*

Public Members

deviceId_t deviceId
: Connection identifier

gapPeriodicAdvSyncMode_t mode

The action to be taken when periodic advertising synchronization information is received

uint16_t skip

The number of periodic advertising packets that can be skipped after a successful receive

uint16_t syncTimeout

Synchronization timeout for the periodic advertising train

bleSyncCteType_t CTEType

0: Do not sync to packets with an AoA Constant Tone Extension 1: Do not sync to packets with an AoD Constant Tone Extension with 1 us slots 2: Do not sync to packets with an AoD Constant Tone Extension with 2 us slots 4: Do not sync to packets without a Constant Tone Extension

struct gapScanningParameters_t

#include <gap_types.h> Scanning parameters; for defaults see gGapDefaultScanningParameters_d.

Public Members

bleScanType_t type

Scanning type. Default: passive.

uint16_t interval

Scanning interval. Default: 10 ms.

uint16_t window

Scanning window. Default: 10 ms.

bleAddressType_t ownAddressType

Indicates whether the address used in scan requests is the public address (BD_ADDR) or the random address (set by Gap_SetRandomAddress). Default: public address. If Controller Privacy is enabled, this parameter is irrelevant as Private Resolvable Addresses are always used.

bleScanningFilterPolicy_t filterPolicy

Indicates whether the advertising packets are filtered using the Filter Accept List. Default: does not use Filter Accept List (scan all).

gapLePhyFlags_t scanningPHYs

Indicates the PHYs on which the advertising packets should be received on the primary advertising channel.

struct gapCreateSyncReqOptions_tag

#include <gap_types.h> Create Sync Request Options

struct gapPeriodicAdvSyncReq_tag

#include <gap_types.h> Periodic Advertising Sync Request parameters

Public Members

gapCreateSyncReqOptions_t options

Bit 0: Filter Policy. Bit 1: Reporting enabled/disabled. Bit 2: Duplicate filtering disabled/enabled.

uint8_t SID

The SID advertised by the periodic advertiser in the ADI field.

bleAddressType_t peerAddressType

Periodic advertiser's address type (Public or Random)

bleDeviceAddress_t peerAddress

Periodic advertiser's address

uint16_t skipCount

The number of consecutive periodic advertising packets that the receiver may skip after successfully receiving a periodic advertising packet.

uint16_t timeout

The maximum permitted time between successful receives. If this time is exceeded, synchronization is lost.

bleSyncCteType_t cteType

Specifies whether to only sync to certain types of CTE

struct gapConnectionRequestParameters_t

#include <gap_types.h> Connection request parameter structure to be used in the Gap_Connect function; for API-defined defaults, use gGapDefaultConnectionRequestParameters_d.

Public Members

uint16_t scanInterval

Scanning interval. Default: 10 ms.

uint16_t scanWindow

Scanning window. Default: 10 ms.

bleInitiatorFilterPolicy_t filterPolicy

Indicates whether the connection request is issued for a specific device or for all the devices in the Filter Accept List. Default: specific device.

bleAddressType_t ownAddressType

Indicates whether the address used in connection requests is the public address (BD_ADDR) or the random address (set by Gap_SetRandomAddress). Default: public address.

bleAddressType_t peerAddressType

When connecting to a specific device (see filterPolicy), this indicates that device's address type. Default: public address.

bleDeviceAddress_t peerAddress

When connecting to a specific device (see filterPolicy), this indicates that device's address.

uint16_t connIntervalMin

The minimum desired connection interval. Default: 100 ms.

uint16_t connIntervalMax

The maximum desired connection interval. Default: 200 ms.

uint16_t connLatency

The desired connection latency (the maximum number of consecutive connection events the Peripheral is allowed to ignore). Default: 0.

uint16_t supervisionTimeout

The maximum time interval between consecutive over-the-air packets; if this timer expires, the connection is dropped. Default: 10 s.

uint16_t connEventLengthMin

The minimum desired connection event length. Default: 0 ms.

uint16_t connEventLengthMax

The maximum desired connection event length. Default: maximum possible, ~41 s. (lets the Controller decide).

bool_t usePeerIdentityAddress

If Controller Privacy is enabled and this parameter is TRUE, the address defined in the peerAddressType and peerAddress is an identity address. Otherwise, it is a device address.

gapLePhyFlags_t initiatingPHYs

Indicates the PHY on which the advertising packets should be received on the primary advertising channel and the PHY for which connection parameters have been specified.

struct gapConnectionFromPawrParameters_t

#include <gap_types.h> Connection request parameter structure to be used in the Gap_ConnectFromPawr function

Public Members

uint16_t scanInterval

Scanning interval. Default: 10 ms.

uint16_t scanWindow

Scanning window. Default: 10 ms.

bleInitiatorFilterPolicy_t filterPolicy

Indicates whether the connection request is issued for a specific device or for all the devices in the Filter Accept List. Default: specific device.

bleAddressType_t ownAddressType

Indicates whether the address used in connection requests is the public address (BD_ADDR) or the random address (set by Gap_SetRandomAddress). Default: public address.

bleAddressType_t peerAddressType

When connecting to a specific device (see filterPolicy), this indicates that device's address type. Default: public address.

bleDeviceAddress_t peerAddress

When connecting to a specific device (see filterPolicy), this indicates that device's address.

uint16_t connIntervalMin

The minimum desired connection interval. Default: 100 ms.

uint16_t connIntervalMax

The maximum desired connection interval. Default: 200 ms.

uint16_t connLatency

The desired connection latency (the maximum number of consecutive connection events the Peripheral is allowed to ignore). Default: 0.

uint16_t supervisionTimeout

The maximum time interval between consecutive over-the-air packets; if this timer expires, the connection is dropped. Default: 10 s.

uint16_t connEventLengthMin

The minimum desired connection event length. Default: 0 ms.

uint16_t connEventLengthMax

The maximum desired connection event length. Default: maximum possible, ~41 s. (lets the Controller decide).

bool_t usePeerIdentityAddress

If Controller Privacy is enabled and this parameter is TRUE, the address defined in the peerAddressType and peerAddress is an identity address. Otherwise, it is a device address.

gapLePhyFlags_t initiatingPHYs

Indicates the PHY on which the advertising packets should be received on the primary advertising channel and the PHY for which connection parameters have been specified.

uint8_t advHandle

Advertising handle identifying the periodic advertising train.

uint8_t subevent

Subevent where the connection request is to be sent.

struct gapConnectionParameters_t

#include <gap_types.h> Connection parameters as received in the gConnEvtConnected_c connection event.

Public Members

uint16_t connInterval

Interval between connection events.

uint16_t connLatency

Number of consecutive connection events the Peripheral may ignore.

uint16_t supervisionTimeout

The maximum time interval between consecutive over-the-air packets; if this timer expires, the connection is dropped.

bleCentralClockAccuracy_t centralClockAccuracy

Accuracy of central's clock, allowing for frame detection optimizations.

struct gapConnectionSubrateParameters_t

#include <gap_types.h> Connection subrate parameters

Public Members

uint16_t subrateMin

Minimum subrate factor to be applied to the underlying connection interval.

uint16_t subrateMax

Maximum subrate factor to be applied to the underlying connection interval.

uint16_t latencyMax

Maximum Peripheral latency for the connection in units of subrated connection intervals.

uint16_t continuationNumber

Minimum number of underlying connection events to remain active after a packet containing a Link Layer PDU with a non-zero Length field is sent or received.

uint16_t supervisionTimeout

The maximum time interval between consecutive over-the-air packets in 10ms units; if this timer expires, the connection is dropped.

struct gapGenerateDHKeyV2Params_t

#include <gap_types.h> DH Key Generate V2

Public Members

ecdhPublicKey_t remoteP256PublicKey

The remote P-256 public key

gapPrivateKeyType_t keyType

The private key type used for generating the DH key

struct gapConnectionlessCteTransmitParams_t

#include <gap_types.h> Parameter structure to be used in the Gap_SetConnectionlessCteTransmitParameters function.

Public Members

uint8_t handle

Advertising set handle.

uint8_t cteLength

Constant Tone Extension length in 8 us.

bleCteType_t cteType

Type of CTE.

uint8_t cteCount

Number of CTEs to transmit in each periodic advertising interval.

uint8_t switchingPatternLength

Number of Antenna IDs in pattern.

uint8_t aAntennaIds[1]

List of Antenna IDs in pattern.

struct gapConnectionlessIqSamplingParams_t

#include <gap_types.h> Parameter structure to be used in the Gap_EnableConnectionlessIqSampling function.

Public Members

bleIqSamplingEnable_t iqSamplingEnable
: Enable or disable IQ sampling.

bleSlotDurations_t slotDurations
: Switching and sampling slot durations.

uint8_t maxSampledCtes
: Maximum number of CTEs to sample and report in each periodic adv interval.

uint8_t switchingPatternLength
: Number of Antenna IDs in pattern.

uint8_t aAntennaIds[1]
: List of Antenna IDs in pattern.

struct gapConnectionCteTransmitParams_t
: *#include <gap_types.h>* Parameter structure to be used in the Gap_SetConnectionCteTransmitParameters function.

Public Members

bleCteAllowedTypesMap_t cteTypes
: Allowed CTE types.

uint8_t switchingPatternLength
: Number of Antenna IDs in pattern.

uint8_t aAntennaIds[1]
: List of Antenna IDs in pattern.

struct gapConnectionCteReceiveParams_t
: *#include <gap_types.h>* Parameter structure to be used in the Gap_SetConnectionCteReceiveParameters function.

Public Members

bleIqSamplingEnable_t iqSamplingEnable
: Enable or disable IQ sampling.

bleSlotDurations_t slotDurations
: Switching and sampling slot durations.

uint8_t switchingPatternLength
: Number of Antenna IDs in pattern.

uint8_t aAntennaIds[1]
: List of Antenna IDs in pattern.

struct gapConnectionCteReqEnableParams_t

#include <gap_types.h> Parameter structure to be used in the Gap_EnableConnectionCteRequest function.

Public Members

bleCteReqEnable_t cteReqEnable

Enable or disable CTE Req procedure.

uint16_t cteReqInterval

Requested interval for initiating CTE Req procedure.

uint8_t requestedCteLength

Minimum length of CTEs requested in 8 us units.

bleCteType_t requestedCteType

Requested types of CTE.

struct gapPathLossReportingParams_t

#include <gap_types.h> Parameter structure to be used in the Gap_SetPathLossReportingParameters function.

Public Members

uint8_t highThreshold

High threshold for the path loss. Units: dB.

uint8_t highHysteresis

Hysteresis value for the high threshold. Units: dB.

uint8_t lowThreshold

Low threshold for the path loss. Units: dB.

uint8_t lowHysteresis

Hysteresis value for the low threshold. Units: dB.

uint16_t minTimeSpent

Minimum time in number of connection events to be observed once the path crosses the threshold before an event is generated.

struct gapAdStructure_t

#include <gap_types.h> Definition of an AD Structure as contained in Advertising and Scan Response packets. An Advertising or Scan Response packet contains several AD Structures.

Public Members

uint8_t length

Total length of the [adType + aData] fields. Equal to 1 + lengthOf(aData).

gapAdType_t adType

AD Type of this AD Structure.

uint8_t *aData

Data contained in this AD Structure; length of this array is equal to (*gapAdStructure_t.length* - 1).

struct gapAdvertisingData_t

#include <gap_types.h> Advertising Data structure : a list of several *gapAdStructure_t* structures.

Public Members

uint8_t cNumAdStructures

Number of AD Structures.

gapAdStructure_t *aAdStructures

Array of AD Structures.

struct gapAdvertisingDecisionData_t

#include <gap_types.h> Extended Advertising Decision Data structure.

Public Members

uint8_t *pKey

Pointer to the key for the resolvable tag. When pKey != NULL Decision data should contain only arbitrary data or pDecisionData should be NULL.

uint8_t *pPrand

Used only when pKey != NULL. When pPrand != NULL it should point the 3 bytes value of the prand. Otherwise it will be generated by the host.

uint8_t *pDecisionData

Pointer to the decision data. When pDecisionData != NULL decision data may contain the resolvable tag and/or arbitrary data.

uint8_t dataLength

The length of the decision data pointed by pDecisionData. When pKey is NULL it should not exceed 8. Otherwise it should not exceed 2

bool_t resolvableTagPresent

When pKey is NULL it indicates whether decision data contains the resolvable tag. In this case the 6 <= dataLength <= 8

struct gapDecisionInstructionsData_tag

#include <gap_types.h>

struct gapSubeventDataStructure_t

#include <gap_types.h> Definition of a Subevent Data structure as contained in Periodic Advertising subevents.

Public Members

uint8_t subevent

Subevent index for this data.

uint8_t responseSlotStart

The first response slots to be used in this subevent.

uint8_t responseSlotCount

The number of response slots to be used.

gapAdvertisingData_t *pAdvertisingData

Advertising data.

struct gapPeriodicAdvertisingSubeventData_t

#include <gap_types.h> Advertising Data structure : a list of several *gapAdStructure_t* structures.

Public Members

uint8_t cNumSubevents

Number of subevents.

gapSubeventDataStructure_t *aSubeventDataStructures

Data for each subevent.

struct gapPeriodicAdvertisingResponseData_t

#include <gap_types.h> Periodic Advertising Response data

Public Members

uint16_t requestEvent

The value of paEventCounter (see [Vol 6] Part B, Section 4.4.2.1) for the periodic advertising packet that the Host is responding to

uint8_t requestSubevent

The subevent for the periodic advertising packet that the Host is responding to.

uint8_t responseSubevent
: Used to identify the subevent of the PAwR train.

uint8_t responseSlot
: Used to identify the response slot of the PAwR train.

gapAdvertisingData_t *pResponseData
: Response data.

struct gapPeriodicSyncSubeventParameters_t
: *#include <gap_types.h>* Periodic Sync Subevent Parameters

Public Members

uint16_t perAdvProperties
: Bit 6: Include TxPower in the advertising PDU

uint8_t numSubevents
: Number of subevents.

uint8_t aSubevents[1]
: List of subevents

struct gapExtScanNotification_t
: *#include <gap_types.h>*

Public Members

uint8_t handle
: Advertising Handle

bleAddressType_t scannerAddrType
: Scanner device's address type.

bleDeviceAddress_t aScannerAddr
: Scanner device's address.

bool_t scannerAddrResolved
: Whether the address corresponds to Resolved Private Address.

struct gapAdvertisingSetTerminated_t
: *#include <gap_types.h>*

Public Members

bleResult_t status
: Status of advertising set termination

uint8_t handle
: Advertising Handle

deviceId_t deviceId
: Valid only if the advertising ended with a connection

uint8_t numCompletedExtAdvEvents
: Number of advertising events sent by Controller

struct gapPerAdvSubeventDataRequest_t
: *#include <gap_types.h>*

Public Members

uint8_t handle
: Used to identify a periodic advertising train.

uint8_t subeventStart
: The first subevent that data is requested for.

uint8_t subeventDataCount
: The number of subevents that data is requested for.

struct gapPerAdvResponse_t
: *#include <gap_types.h>*

struct gapAdvertisingEvent_t
: *#include <gap_types.h>* Advertising event structure: type + data.

Public Members

gapAdvertisingEventType_t eventType
: Event type.

union *gapAdvertisingEvent_t* eventData
: Event data, to be interpreted according to *gapAdvertisingEvent_t.eventType*.

struct gapScannedDevice_t
: *#include <gap_types.h>* Scanned device information structure, obtained from LE Advertising Reports.

Public Members

bleAddressType_t addressType

Device's advertising address type.

bleDeviceAddress_t aAddress

Device's advertising address.

int8_t rssi

RSSI on the advertising channel; may be compared to the TX power contained in the AD Structure of type gAdTxPowerLevel_c to estimate distance from the advertiser.

uint8_t dataLength

Length of the advertising or scan response data.

uint8_t *data

Advertising or scan response data.

bleAdvertisingReportEventType_t advEventType

Advertising report type, indicating what type of event generated this data (advertising, scan response).

bool_t directRpaUsed

TRUE if directed advertising with Resolvable Private Address as Direct Address was detected while Enhanced Privacy is enabled.

bleDeviceAddress_t directRpa

Resolvable Private Address set as Direct Address for directed advertising. Valid only when directRpaUsed is TRUE.

bool_t advertisingAddressResolved

If this is TRUE, the address contained in the addressType and aAddress fields is the identity address of a resolved RPA from the Advertising Address field. Otherwise, the address from the respective fields is the public or random device address contained in the Advertising Address field.

struct gapExtScannedDevice_t

#include <gap_types.h>

Public Members

bleAddressType_t addressType

Device's advertising address type.

bleDeviceAddress_t aAddress

Device's advertising address.

uint8_t SID

Advertising set id

bool_t advertisingAddressResolved

If this is TRUE, the address contained in the addressType and aAddress fields is the identity address of a resolved RPA from the Advertising Address field. Otherwise, the address from the respective fields is the public or random device address contained in the Advertising Address field.

bleAdvReportEventProperties_t advEventProperties

Advertising report properties, indicating what type of event generated this data (advertising, scan response).

int8_t rssi

RSSI on the advertising channel; may be compared to the TX power contained in the AD Structure of type gAdTxPowerLevel_c to estimate distance from the advertiser.

int8_t txPower

The Tx power level of the advertiser

uint8_t primaryPHY

Advertiser PHY for primary channel

uint8_t secondaryPHY

Advertiser PHY for secondary channel

uint16_t periodicAdvInterval

Interval of the periodic advertising. Zero if not periodic advertising.

bool_t directRpaUsed

TRUE if directed advertising with Resolvable Private Address as Direct Address was detected while Enhanced Privacy is enabled.

bleAddressType_t directRpaType

Address type for directed advertising. Valid only when directRpaUsed is TRUE.

bleDeviceAddress_t directRpa

Resolvable Private Address set as Direct Address for directed advertising. Valid only when directRpaUsed is TRUE.

uint16_t dataLength

Length of the advertising or scan response data.

uint8_t *pData

Advertising or scan response data.

struct gapPeriodicScannedDevice_t

#include <gap_types.h>

Public Members

uint16_t syncHandle

Sync Handle

int8_t txPower

The Tx power level of the advertiser

int8_t rssi

RSSI on the advertising channel; may be compared to the TX power contained in the AD Structure of type gAdTxPowerLevel_c to estimate distance from the advertiser.

bleCteType_t cteType

Type of Constant Tone Extension in the periodic advertising packets.

uint16_t dataLength

Length of the advertising or scan response data.

uint8_t *pData

Advertising or scan response data.

struct gapPeriodicScannedDeviceV2_t

#include <gap_types.h>

Public Members

uint16_t syncHandle

Sync Handle

int8_t txPower

The Tx power level of the advertiser

int8_t rssi

RSSI on the advertising channel; may be compared to the TX power contained in the AD Structure of type gAdTxPowerLevel_c to estimate distance from the advertiser.

bleCteType_t cteType

Type of Constant Tone Extension in the periodic advertising packets.

uint16_t periodicEventCounter

The value of paEventCounter (see [Vol 6] Part B, Section 4.4.2.1) for the reported periodic advertising packet.

uint8_t subevent

Subevent number.

uint16_t dataLength

Length of the advertising or scan response data.

uint8_t *pData
Advertising or scan response data.

struct gapSyncEstbEventData_t
#include <gap_types.h>

Public Members

bleResult_t status
Status of the Sync Established Event

uint16_t syncHandle
Sync Handle

uint8_t SID
Value of the Advertising SID subfield in the ADI field of the PDU

bleAddressType_t peerAddressType
Advertiser Address Type

bleDeviceAddress_t peerAddress
Advertiser Address

gapLePhyMode_t PHY
Advertiser PHY

uint16_t periodicAdvInterval
Periodic advertising interval

bleAdvertiserClockAccuracy_t advertiserClockAccuracy
Advertiser Clock Accuracy

uint8_t numSubevents
Only relevant for v2 of the event, otherwise value is 0

uint8_t subeventInterval
Only relevant for v2 of the event, otherwise value is 0

uint8_t responseSlotDelay
Only relevant for v2 of the event, otherwise value is 0

uint8_t responseSlotSpacing
Only relevant for v2 of the event, otherwise value is 0

struct gapSyncLostEventData_t
#include <gap_types.h>

Public Members

uint16_t syncHandle
Sync Handle

struct gapConnectionlessIqReport_t
#include <gap_types.h>

Public Members

uint16_t syncHandle
Sync Handle.

uint8_t channelIndex
Index of the channel on which the packet was received.

int16_t rssi
RSSI of the packet.

uint8_t rssiAntennaId
Antenna ID.

bleCteType_t cteType
Type of CTE on the received packet (AoA, AoD 1 us, AoD 2 us).

bleSlotDurations_t slotDurations
Durations of switching/sampling slots.

bleIqReportPacketStatus_t packetStatus
Packet status, information about CRC.

uint16_t periodicEventCounter
The value of paEventCounter for the reported AUX_SYNC_IND PDU.

uint8_t sampleCount
Total number of sample pairs.

int8_t *aI_samples
List of sampleCount I_samples.

int8_t *aQ_samples
List of sampleCount Q_samples.

struct gapMonAdvReportReport_t
#include <gap_types.h>

Public Members

bleAddressType_t peerAddressType
Advertiser Address Type

bleDeviceAddress_t peerAddress
Advertiser Address

bleMonAdvCondition_t condition
Condition parameter

struct gapScanningEvent_t
#include <gap_types.h> Scanning event structure: type + data.

Public Members

gapScanningEventType_t eventType
Event type.

union *gapScanningEvent_t* eventData
Event data, to be interpreted according to *gapScanningEvent_t.eventType*.

struct gapConnectedEvent_t
#include <gap_types.h> Event data structure for the gConnEvtConnected_c event.

Public Members

gapConnectionParameters_t connParameters
Connection parameters established by the Controller.

bleAddressType_t peerAddressType
Connected device's address type.

bleDeviceAddress_t peerAddress
Connected device's address.

bool_t peerRpaResolved
If this is TRUE, the address defined by peerAddressType and peerAddress is the identity address of the peer, and the peer used an RPA that was resolved by the Controller and is contained in the peerRpa field. Otherwise, it is a device address. This parameter is irrelevant if Controller Privacy is not enabled.

bleDeviceAddress_t peerRpa
Peer Resolvable Private Address if Controller Privacy is active and peerRpaResolved is TRUE.

bool_t localRpaUsed

If this is TRUE, the Controller has used an RPA contained in the localRpa field. This parameter is irrelevant if Controller Privacy is not enabled.

bleDeviceAddress_t localRpa

Local Resolvable Private Address if Controller Privacy is active and localRpaUsed is TRUE.

bleLlConnectionRole_t connectionRole

Connection Role - central or peripheral.

uint8_t advHandle

Only relevant if the connection was from PAWR.

uint16_t syncHandle

Only relevant if the connection was from PAWR.

struct gapKeyExchangeRequestEvent_t

#include <gap_types.h> Event data structure for the gConnEvtKeyExchangeRequest_c event.

Public Members

gapSmpKeyFlags_t requestedKeys

Mask identifying the keys being requested.

uint8_t requestedLtkSize

Requested size of the encryption key.

struct gapKeysReceivedEvent_t

#include <gap_types.h> Event data structure for the gConnEvtKeysReceived_c event.

Public Members

gapSmpKeys_t *pKeys

The SMP keys distributed by the peer.

struct gapAuthenticationRejectedEvent_t

#include <gap_types.h> Event data structure for the gConnEvtAuthenticationRejected_c event.

Public Members

gapAuthenticationRejectReason_t rejectReason

Peripheral's reason for rejecting the authentication.

struct gapPairingCompleteEvent_t

#include <gap_types.h> Event data structure for the gConnEvtPairingComplete_c event.

Public Members

bool_t pairingSuccessful

TRUE if pairing succeeded, FALSE otherwise.

union *gapPairingCompleteEvent_t* pairingCompleteData

Information of completion, selected upon the value of *gapPairingCompleteEvent_t.pairingSuccessful*.

struct gapLongTermKeyRequestEvent_t

#include <gap_types.h> Event data structure for the gConnEvtLongTermKeyRequest_c event.

Public Members

uint16_t ediv

The Encryption Diversifier, as defined by the SMP.

uint8_t aRand[(8U)]

The Random number, as defined by the SMP.

uint8_t randSize

Usually equal to gcMaxRandSize_d.

struct gapEncryptionChangedEvent_t

#include <gap_types.h> Event data structure for the gConnEvtEncryptionChanged_c event.

Public Members

bool_t newEncryptionState

TRUE if link has been encrypted, FALSE if encryption was paused or removed.

struct gapDisconnectedEvent_t

#include <gap_types.h> Event data structure for the gConnEvtDisconnected_c event.

Public Members

gapDisconnectionReason_t reason

Reason for disconnection.

struct gapConnParamsUpdateReq_t

#include <gap_types.h> Event data structure for the gConnEvtParameterUpdateRequest_c event.

Public Members

uint16_t intervalMin

Minimum interval between connection events.

uint16_t intervalMax

Maximum interval between connection events.

uint16_t peripheralLatency

Number of consecutive connection events the Peripheral may ignore.

uint16_t timeoutMultiplier

The maximum time interval between consecutive over-the-air packets; if this timer expires, the connection is dropped.

struct gapConnParamsUpdateComplete_t

#include <gap_types.h> Event data structure for the gConnEvtParameterUpdateComplete_c event.

Public Members

uint16_t connInterval

Interval between connection events.

uint16_t connLatency

Number of consecutive connection events the Peripheral may ignore.

uint16_t supervisionTimeout

The maximum time interval between consecutive over-the-air packets; if this timer expires, the connection is dropped.

struct gapConnLeDataLengthChanged_t

#include <gap_types.h> Event data structure for the gConnEvtLeDataLengthChanged_c event.

Public Members

uint16_t maxTxOctets

The maximum number of payload octets in a Link Layer Data Channel PDU to transmit on this connection.

uint16_t maxTxTime

The maximum time that the local Controller will take to send a Link Layer Data Channel PDU on this connection.

uint16_t maxRxOctets

The maximum number of payload octets in a Link Layer Data Channel PDU to receive on this connection.

uint16_t maxRxTime

The maximum time that the local Controller will take to receive a Link Layer Data Channel PDU on this connection.

struct gapConnIqReport_t

#include <gap_types.h> Event data structure for the gConnEvtIqReportReceived_c event.

Public Members

gapLePhyMode_t rxPhy

Identifies receiver PHY for this connection.

uint8_t dataChannelIndex

Index of the data channel on which the Data Physical Channel PDU was received.

int16_t rssi

RSSI of the packet.

uint8_t rssiAntennaId

Antenna ID.

bleCteType_t cteType

Type of CTE on the received packet (AoA, AoD 1 us, AoD 2 us).

bleSlotDurations_t slotDurations

Durations of switching/sampling slots.

bleIqReportPacketStatus_t packetStatus

Packet status, information about CRC.

uint16_t connEventCounter

The value of the connEventCounter for the reported PDU.

uint8_t sampleCount

Total number of sample pairs.

int8_t *aI_samples

List of sampleCount I_samples

int8_t *aQ_samples

List of sampleCount Q_samples

struct gapConnCteRequestFailed_t

#include <gap_types.h> Event data structure for the gConnEvtCteRequestFailed_c event.

Public Members

bleResult_t status

Status (0x00 - received response but without CTE, 0x01-0xFF - peer rejected request

struct gapPathLossThresholdEvent_t

#include <gap_types.h> Event data structure for the gConnEvtPathLossThreshold_c event.

Public Members

uint8_t currentPathLoss

Current path loss. Units: dB.

blePathLossThresholdZoneEntered_t zoneEntered

Low, middle or high.

struct gapTransmitPowerReporting_t

#include <gap_types.h> Event data structure for the gConnEvtTransmitPowerReporting_c event.

Public Members

bleTxPowerReportingReason_t reason

Reason for generating this event

- local tx power changed
- remote tx power changed
- a HCI_LE_Read_Remote_Transmit_Power_Level command completed

blePowerControlPhyType_t phy

The PHY for which the event is generated.

int8_t txPowerLevel

New transmit power level on this connection and PHY.

bleTxPowerLevelFlags_t flags

Tx power level flags.

int8_t delta

Change in tx power level. Units: dB.

struct gapSubrateChangeEvent_t

#include <gap_types.h> Event data structure for the gConnEvtLeSubrateChange_c event.

Public Members

uint16_t subrateFactor

subrate factor applied to the underlying connection interval.

uint16_t peripheralLatency

Peripheral latency for the connection in units of subrated connection intervals.

uint16_t continuationNumber

Minimum number of underlying connection events to remain active after a packet containing a Link Layer PDU with a non-zero Length field is sent or received.

uint16_t supervisionTimeout

The maximum time interval between consecutive over-the-air packets in 10ms units; if this timer expires, the connection is dropped.

struct gapTransmitPowerInfo_t

#include <gap_types.h> Event data structure for the gConnEvtEnhancedReadTransmitPowerLevel_c event.

Public Members

blePowerControlPhyType_t phy

The PHY for which the event is generated.

int8_t currTxPowerLevel

Current tx power level on this connection and PHY.

int8_t maxTxPowerLevel

Maximum tx power level on this connection and PHY.

struct gapEattConnectionRequest_t

#include <gap_types.h> Event data structure for the gConnEvtEattConnectionRequest_c event.

struct gapEattConnectionComplete_t

#include <gap_types.h> Event data structure for the gConnEvtEattConnectionComplete_c event.

struct gapEattReconfigureResponse_t

#include <gap_types.h> Event data structure for the gConnEvtEattChannelReconfigureResponse_c event.

struct gapEattBearerStatusNotification_t

#include <gap_types.h> Event data structure for the bearer status update event.

struct gapHandoverConnectedEvent_t

#include <gap_types.h> Event data structure for the gConnEvtHandoverConnected_c event.

Public Members

bleAddressType_t peerAddressType
Connected device's address type.

bleDeviceAddress_t peerAddress
Connected device's address.

bleLlConnectionRole_t connectionRole
Connection Role - master or slave.

struct gapHandoverDisconnectedEvent_t
#include <gap_types.h> Event data structure for the gHandoverDisconnected_c event.

Public Members

bleResult_t status
Status for the handover disconnect command

struct gapConnectionEvent_t
#include <gap_types.h> Connection event structure: type + data.

Public Members

gapConnectionEventType_t eventType
Event type

union *gapConnectionEvent_t* eventData
Event data, to be interpreted according to *gapConnectionEvent_t.eventType*.

struct gapIdentityInformation_t
#include <gap_types.h> Identity Information structure definition

Public Members

bleIdentityAddress_t identityAddress
Identity Address - Public or Random Static

uint8_t irk[(16U)]
Identity Resolving Key - must not be all-zero if Network Privacy is used

blePrivacyMode_t privacyMode
Privacy mode to be used for the entry on the resolving list

struct gapAutoConnectParams_t
#include <gap_types.h> Parameters for the Auto Connect Scan Mode.

Public Members

uint8_t cNumAddresses

Number of device addresses to automatically connect to.

bool_t writeInFilterAcceptList

If set to TRUE, the device addresses are written in the Filter Accept List before scanning is enabled.

gapConnectionRequestParameters_t *aAutoConnectData

The array of connection request parameters, of size equal to cNumAddresses.

struct gapHostVersion_tag

#include <gap_types.h>

union testParameters

Public Members

uint8_t resolvableTagKey[(16U)]

struct *gapDecisionInstructionsData_tag* arbitraryData

struct *gapDecisionInstructionsData_tag* rssi

struct *gapDecisionInstructionsData_tag* pathLoss

struct *gapDecisionInstructionsData_tag* advA

gapDecisionInstructionsAdvMode_t advMode

struct arbitraryData

struct rssi

struct pathLoss

struct advA

union eventData

Public Members

bleResult_t failReason

Event data for gAdvertisingCommandFailed_c event type: reason of failure to enable or disable advertising.

gapExtScanNotification_t scanNotification

Event data for gExtScanNotification_c event type: Scan Request Received Event.

gapAdvertisingSetTerminated_t advSetTerminated

Event received when advertising in a given advertising set has stopped.

gapPerAdvSubeventDataRequest_t subeventDataRequest

Event received when doing PAWR.

gapPerAdvResponse_t perAdvResponse

Periodic Advertising Response.

uint8_t advHandle

Event data for gExtAdvertisingStateChanged_c event type.

union eventData

Public Members

bleResult_t failReason

Event data for gScanCommandFailed_c or gPeriodicAdvSyncEstablished_c event type: reason of failure to enable/disable scanning or to establish sync.

gapScannedDevice_t scannedDevice

Event data for gDeviceScanned_c event type: scanned device information.

gapExtScannedDevice_t extScannedDevice

Event data for gExtDeviceScanned_c event type: extended scanned device information.

gapPeriodicScannedDevice_t periodicScannedDevice

Event data for gPeriodicDeviceScanned_c event type.

gapPeriodicScannedDeviceV2_t periodicScannedDeviceV2

Event data for gPeriodicDeviceScannedV2_c event type.

gapSyncEstbEventData_t syncEstb

Event data for gPeriodicAdvSyncEstablished_c event type: Sync handle information for the application.

gapSyncLostEventData_t syncLost

Event data for gPeriodicAdvSyncLost_c event type: Sync handle information for the application.

gapConnectionlessIqReport_t iqReport

Event data for gConnectionlessIqReportReceived_c event type: IQ information for the application.

gapMonAdvReportReport_t monAdvReport

Event data for gMonAdvReportEventReceived_c event type.

union pairingCompleteData

Public Members

bool_t withBonding

If pairingSuccessful is TRUE, this indicates whether the devices bonded.

bleResult_t failReason

If pairingSuccessful is FALSE, this contains the reason of failure.

union eventData

Public Members

gapConnectedEvent_t connectedEvent

Data for gConnEvtConnected_c: information about the connection parameters.

gapPairingParameters_t pairingEvent

Data for gConnEvtPairingRequest_c, gConnEvtPairingResponse_c: pairing parameters.

gapAuthenticationRejectedEvent_t authenticationRejectedEvent

Data for gConnEvtAuthenticationRejected_c: reason for rejection.

gapPeripheralSecurityRequestParameters_t peripheralSecurityRequestEvent

Data for gConnEvtPeripheralSecurityRequest_c: Peripheral's security requirements.

gapKeyExchangeRequestEvent_t keyExchangeRequestEvent

Data for gConnEvtKeyExchangeRequest_c: mask indicating the keys that were requested by the peer.

gapKeysReceivedEvent_t keysReceivedEvent

Data for gConnEvtKeysReceived_c: the keys received from the peer.

gapPairingCompleteEvent_t pairingCompleteEvent

Data for gConnEvtPairingComplete_c: fail reason or (if successful) bonding state.

gapLongTermKeyRequestEvent_t longTermKeyRequestEvent

Data for gConnEvtLongTermKeyRequest_c: encryption diversifier and random number.

gapEncryptionChangedEvent_t encryptionChangedEvent
: Data for gConnEvtEncryptionChanged_c: new encryption state.

gapDisconnectedEvent_t disconnectedEvent
: Data for gConnEvtDisconnected_c: reason for disconnection.

int8_t rssi_dBm
: Data for gConnEvtRssiRead_c: value of the RSSI in dBm.

int8_t txPowerLevel_dBm
: Data for gConnEvtTxPowerLevelRead_c: value of the TX power.

bleResult_t failReason
: Data for gConnEvtPowerReadFailure_c: reason for power reading failure.

uint32_t passkeyForDisplay

gapConnParamsUpdateReq_t connectionUpdateRequest
: Data for gConnEvtParameterUpdateRequest_c: connection parameters update.

gapConnParamsUpdateComplete_t connectionUpdateComplete
: Data for gConnEvtParameterUpdateComplete_c: connection parameters update.

gapConnLeDataLengthChanged_t leDataLengthChanged
: Data for gConnEvtLeDataLengthChanged_c: new data length parameters

gapKeypressNotification_t incomingKeypressNotification

uint32_t numericValueForDisplay

bleChannelMap_t channelMap
: Data for gConnEvtChannelMapRead_c: channel map read from the Controller

gapConnIqReport_t connIqReport
: Data for gConnEvtIqReportReceived_c: IQ information received from a peer

gapConnCteRequestFailed_t cteRequestFailedEvent
: Data for gConnEvtCteRequestFailed_c: CTE Request to peer has failed

bleResult_t perAdvSyncTransferStatus

gapPathLossThresholdEvent_t pathLossThreshold
: Data for gConnEvtPathLossThreshold_c: current path loss and zone entered.

gapTransmitPowerReporting_t transmitPowerReporting
: Data for gConnEvtTransmitPowerReporting_c: changes in power levels.

gapTransmitPowerInfo_t transmitPowerInfo

Data for gConnEvtEnhancedReadTransmitPowerLevel_c: local power level information.

gapEattConnectionRequest_t eattConnectionRequest

Data for gConnEvtEattConnectionRequest_c: notification of L2Cap Enhanced Connect request for EATT.

gapEattConnectionComplete_t eattConnectionComplete

Data for gConnEvtEattConnectionComplete_c: result of *Gap_EattConnectionRequest()*.

gapEattReconfigureResponse_t eattReconfigureResponse

Data for gConnEvtEattChannelReconfigureResponse_c: result of *Gap_EattReconfigureRequest()*.

gapEattBearerStatusNotification_t eattBearerStatusNotification

Data for gConnEvtEattBearerStatusNotification_c: bearer status update.

gapHandoverConnectedEvent_t handoverConnectedEvent

Data for gConnEvtHandoverConnected_c: information about the connection parameters.

gapHandoverDisconnectedEvent_t handoverDisconnectedEvent

Data for gHandoverDisconnected_c: status of the Gap_HandoverDisconnect.

bleResult_t smError

Data for gConnEvtSmError_c: SM error status.

gapSubrateChangeEvent_t gapSubrateChangeEvent

Data for gConnEvtLeSubrateChange_c: connection parameters update.

uint8_t remoteFeatures[8U]

Data for gConnEvtRemoteFeaturesRead_c: 8-byte mask of features supported by the peer.

GATT

enum attErrorCode_t

ATT error codes

Values:

enumerator gAttErrCodeNoError_c

No error has occured.

enumerator gAttErrCodeInvalidHandle_c

The attribute handle given was not valid on this server.

enumerator gAttErrCodeReadNotPermitted_c

The attribute cannot be read.

enumerator gAttErrCodeWriteNotPermitted_c
The attribute cannot be written.

enumerator gAttErrCodeInvalidPdu_c
The attribute PDU was invalid.

enumerator gAttErrCodeInsufficientAuthentication_c
The attribute requires authentication before it can be read or written.

enumerator gAttErrCodeRequestNotSupported_c
ATT Server does not support the request received from the client.

enumerator gAttErrCodeInvalidOffset_c
Offset specified was past the end of the attribute.

enumerator gAttErrCodeInsufficientAuthorization_c
The attribute requires authorization before it can be read or written.

enumerator gAttErrCodePrepareQueueFull_c
Too many prepare writes have been queued.

enumerator gAttErrCodeAttributeNotFound_c
No attribute found within the given attribute handle range.

enumerator gAttErrCodeAttributeNotLong_c
The attribute cannot be read using the ATT_READ_BLOB_REQ PDU.

enumerator gAttErrCodeInsufficientEncryptionKeySize_c
The Encryption Key Size used for encrypting this link is too short.

enumerator gAttErrCodeInvalidAttributeValueLength_c
The attribute value length is invalid for the operation.

enumerator gAttErrCodeUnlikelyError_c
The attribute request could not be completed due to an unlikely error.

enumerator gAttErrCodeInsufficientEncryption_c
The attribute requires encryption before it can be read or written.

enumerator gAttErrCodeUnsupportedGroupType_c
The attribute type is not a supported grouping attribute.

enumerator gAttErrCodeInsufficientResources_c
Insufficient Resources to complete the request.

enumerator gAttErrCodeDatabaseOutOfSync_c
The server requests the client to rediscover the database.

enumerator gAttErrCodeValueNotAllowed_c
The attribute parameter value was not allowed.

enumerator gAttErrCodeWriteRequestRejected_c
Write request cannot be fulfilled for reasons other than permissions.

enumerator gAttErrCodeCccdImproperlyConfigured_c
CCCD is not configured according to the requirements of the profile or service.

enumerator gAttErrCodeProcedureAlreadyInProgress_c
Profile or service request cannot be serviced because another operation is still in progress.

enumerator gAttErrCodeOutOfRange_c
Attribute value is out of range as defined by a profile or service specification.

enum gattCachingClientState_c
GATT Caching Client states
Values:

enumerator gGattClientChangeUnaware_c
Gatt client is “change-unaware” regarding changes in the database definitions on the Server.

enumerator gGattClientStateChangePending_c
Gatt client is in the process of going from “change-unaware” to “change-aware”.

enumerator gGattClientChangeAware_c
Gatt client is “change-aware” regarding the database definitions on the Server.

enum gattClientHashUpdateType_t
Hash Update type
Values:

enumerator gattClientFirstConnection_c
Hash update for the first connection with a peer

enumerator gattClientReconnectBondedPeer_c
Hash update after reconnecting with a bonded peer

enumerator gattClientActiveConnectionUpdate
Hash update when a change occurs during an active connection

enumerator gattClientNoChange
Idle state - no change

enum gattProcedureType_t
GATT Client Procedure type
Values:

enumerator gGattProcExchangeMtu_c
MTU Exchange

enumerator gGattProcDiscoverAllPrimaryServices_c
Primary Service Discovery

enumerator gGattProcDiscoverPrimaryServicesByUuid_c
Discovery of Services by UUID

enumerator gGattProcFindIncludedServices_c
Discovery of Included Services within a Service range

enumerator gGattProcDiscoverAllCharacteristics_c
Characteristic Discovery within Service range

enumerator gGattProcDiscoverCharacteristicByUuid_c
Characteristic Discovery by UUID

enumerator gGattProcDiscoverAllCharacteristicDescriptors_c
Characteristic Descriptor Discovery

enumerator gGattProcReadCharacteristicValue_c
Characteristic Reading using Value handle

enumerator gGattProcReadUsingCharacteristicUuid_c
Characteristic Reading by UUID

enumerator gGattProcReadMultipleCharacteristicValues_c
Reading multiple Characteristics at once

enumerator gGattProcWriteCharacteristicValue_c
Characteristic Writing

enumerator gGattProcReadCharacteristicDescriptor_c
Reading Characteristic Descriptors

enumerator gGattProcWriteCharacteristicDescriptor_c
Writing Characteristic Descriptors

enumerator gGattProcUpdateDatabaseCopy_c
Inform the application to update its database copy

enumerator gGattProcSignalServiceDiscoveryComplete_c
Inform the application that service discovery has finished

enumerator gGattProcReadMultipleVarLengthCharValues_c
Read Multiple Variable Length Characteristic Values

enum gattProcedurePhase_t

GATT Procedure phase

Values:

enumerator gattProcPhaseInitiated

GATT procedure has been initiated.

enumerator gattProcPhaseRunning

GATT procedure is running.

typedef struct *gattService_tag* gattService_t

GATT Service structure definition

typedef uint8_t gattCccdFlags_t

Flags for the value of the Client Characteristic Configuration Descriptor.

bleResult_t Gatt_Init(void)

Initializes the GATT module.

Remark

If the GAP module is present, this function is called internally by *Ble_HostInitialize()*. Otherwise, the application must call this function once at device start-up.

Remark

This function executes synchronously.

Return values

gBleSuccess_c –

bleResult_t Gatt_GetMtu(*deviceId_t* deviceId, uint16_t *pOutMtu)

Retrieves the MTU used with a given connected device.

Remark

This function executes synchronously.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- pOutMtu – **[out]** Pointer to integer to be written.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.

gCccdEmpty_c
: Nothing is enabled.

gCccdNotification_c
: Enables notifications.

gCccdIndication_c
: Enabled indications.

struct gattAttribute_t
: *#include <gatt_types.h>* GATT Attribute structure definition

Public Members

uint16_t handle
: Attribute handle.

bleUuidType_t uuidType
: Type of the UUID.

bleUuid_t uuid
: The attribute's UUID.

uint16_t valueLength
: Length of the attribute value array.

uint16_t maxValueLength
: Maximum length of the attribute value array; if this is set to 0, then the attribute's length is fixed and cannot be changed.

uint8_t *paValue
: Attribute value array.

struct gattCharacteristic_t
: *#include <gatt_types.h>* GATT Characteristic structure definition

Public Members

gattCharacteristicPropertiesBitFields_t properties
: Characteristic Properties as defined by GATT.

gattAttribute_t value
: Characteristic Value attribute.

uint8_t cNumDescriptors
: Size of the Characteristic Descriptors array.

gattAttribute_t *aDescriptors

Characteristic Descriptors array.

struct gattService_tag

#include <gatt_types.h> GATT Service structure definition

Public Members

uint16_t startHandle

The handle of the Service Declaration attribute.

uint16_t endHandle

The last handle belonging to this Service (followed by another Service declaration of the end of the database).

bleUuidType_t uuidType

Service UUID type.

bleUuid_t uuid

Service UUID.

uint8_t cNumCharacteristics

Size of the Characteristic array.

gattCharacteristic_t *aCharacteristics

Characteristic array.

uint8_t cNumIncludedServices

Size of the Included Services array.

struct *gattService_tag* *aIncludedServices

Included Services array.

struct gattDbCharPresFormat_t

#include <gatt_types.h> Characteristic Presentation Format Descriptor structure

Public Members

uint8_t format

Format of the value of this characteristic.

int8_t exponent

Exponent field to determine how the value of this characteristic is further formatted.

uint16_t unitUuid16

The unit of this characteristic.

uint8_t ns
: The name space of the description.

uint16_t description
: The description of this characteristic.

struct gattHandleRange_t
: *#include <gatt_types.h>* GATT Handle Range structure definition

Public Members

uint16_t startHandle
: Start Handle.

uint16_t endHandle
: End Handle - shall be greater than or equal to Start Handle.

struct procStatus_t
: *#include <gatt_types.h>* GATT Procedure Status structure definition

Public Members

bool_t isOngoing
: Indicates whether the GATT procedure type is ongoing.

gattProcedureType_t ongoingProcedureType
: Procedure type.

gattProcedurePhase_t ongoingProcedurePhase
: Procedure phase.

struct procDataStruct_t
: *#include <gatt_types.h>* GATT Procedure Data structure definition. Structure members are ordered to minimize the padding size

Public Members

uint16_t index
: Number of entries currently stored.

uint16_t max
: Maximum number of entries to store.

bleUuid_t charUuid
: UUID of the characteristic to be discovered.

bleUuidType_t charUuidType
: UUID type of the characteristic to be discovered.

bool_t reliableLongWrite
: Indicates whether to do reliable long writes.

bool_t bAllocatedArray
: Indicates whether the array is allocated.

union *procDataStruct_t* pOutActualCount
: Pointer to the memory locatio where to store the final number of added entries.

union *procDataStruct_t* array
: Array where data is stored.

union *procDataStruct_t* reqParams
: Parameters of the GATT procedure

union pOutActualCount

Public Members

uint8_t *pCount8b
: Pointer to a uint8_t memory location where to store the final number of added entries.

uint16_t *pCount16b
: Pointer to a uint16_t memory location where to store the final number of added entries.

union array

Public Members

gattService_t *aServices
: Array of services.

gattCharacteristic_t *aChars
: Array of characteristics.

gattAttribute_t *aDescriptors
: Array of descriptors.

uint8_t *aBytes
: Array of bytes.

uint16_t *aHandles
: Array of handles.

union reqParams

Public Members

attReadByGroupTypeRequestParams_t rbgtParams
Read By Group Type Request Parameters.

attFindByTypeValueRequestParams_t fbtvParams
Find By Type Value Request Parameters.

attReadByTypeRequestParams_t rbtParams
Read By Type Request Parameters.

attFindInformationRequestParams_t fiParams
Find Information Request Parameters.

attReadRequestParams_t rParams
Read Request Parameters.

attReadBlobRequestParams_t rbParams
Read Blob Request Parameters.

attReadMultipleRequestParams_t rmParams
Read Multiple Request Parameters.

attVarWriteRequestAndCommandParams_t wParams
Write Request and Write Command Parameters for variable value length.

attPrepareWriteRequestResponseParams_t pwParams
Prepare Write Request and Prepare Write Response Parameters.

attExecuteWriteRequestParams_t ewParams
Execute Write Request Parameters

GATT Client

enum gattProcedureResult_t
GATT Client Procedure Result type

Values:

enumerator gGattProcSuccess_c
The procedure was completed successfully.

enumerator gGattProcError_c
The procedure was terminated due to an error.

typedef void (*gattClientProcedureCallback_t)(*deviceId_t* deviceId, *gattProcedureType_t* procedureType, *gattProcedureResult_t* procedureResult, *bleResult_t* error)

GATT Client Procedure Callback type

typedef void (*gattClientNotificationCallback_t)(*deviceId_t* deviceId, uint16_t characteristicValueHandle, uint8_t *aValue, uint16_t valueLength)

GATT Client Notification Callback prototype

typedef *gattClientNotificationCallback_t* gattClientIndicationCallback_t

GATT Client Indication Callback prototype

typedef void (*gattClientMultipleValueNotificationCallback_t)(*deviceId_t* deviceId, uint8_t *aHandleLenValue, uint32_t totalLength)

GATT Client Multiple Value Notification Callback prototype

typedef void (*gattClientEnhancedProcedureCallback_t)(*deviceId_t* deviceId, *bearerId_t* bearerId, *gattProcedureType_t* procedureType, *gattProcedureResult_t* procedureResult, *bleResult_t* error)

GATT Client Enhanced Procedure Callback type

typedef void (*gattClientEnhancedNotificationCallback_t)(*deviceId_t* deviceId, *bearerId_t* bearerId, uint16_t characteristicValueHandle, uint8_t *aValue, uint16_t valueLength)

GATT Client Enhanced Notification Callback prototype

typedef *gattClientEnhancedNotificationCallback_t* gattClientEnhancedIndicationCallback_t

GATT Client Enhanced Indication Callback prototype

typedef void (*gattClientEnhancedMultipleValueNotificationCallback_t)(*deviceId_t* deviceId, *bearerId_t* bearerId, uint8_t *aHandleLenValue, uint32_t totalLength)

GATT Client Enhanced Multiple Value Notification Callback prototype

procDataStruct_t *pProcedureData[]

bleResult_t GattClient_Init(void)

Initializes the GATT Client functionality.

Remark

This should be called once at device startup, if necessary.

Remark

This function executes synchronously.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_ResetProcedure(void)

Resets any ongoing GATT Client Procedure.

Remark

This function should be called if an ongoing Client procedure needs to be stopped.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_RegisterProcedureCallback(*gattClientProcedureCallback_t* callback)

Installs the application callback for the GATT Client module Procedures.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_RegisterNotificationCallback(*gattClientNotificationCallback_t* callback)

Installs the application callback for Server Notifications.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_RegisterIndicationCallback(*gattClientIndicationCallback_t* callback)

Installs the application callback for Server Indications.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_RegisterMultipleValueNotificationCallback(*gattClientMultipleValueNotificationCallback_t* callback)

Installs the application callback for Server Multiple Value Notification.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_ExchangeMtu(*deviceId_t* deviceId, uint16_t mtu)

Initializes the MTU Exchange procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- mtu – **[in]** Desired MTU size.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.

- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_DiscoverAllPrimaryServices(*deviceId_t* deviceId, *gattService_t* *aOutPrimaryServices, uint8_t maxServiceCount, uint8_t *pOutDiscoveredCount)

Initializes the Primary Service Discovery procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- aOutPrimaryServices – **[out]** Statically allocated array of gattService_t. The GATT module fills each Service's handle range and UUID.
- maxServiceCount – **[in]** Maximum number of services to be filled.
- pOutDiscoveredCount – **[out]** The actual number of services discovered.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_DiscoverPrimaryServicesByUuid(*deviceId_t* deviceId, *bleUuidType_t* uuidType, const *bleUuid_t* *pUuid, *gattService_t* *aOutPrimaryServices, uint8_t maxServiceCount, uint8_t *pOutDiscoveredCount)

Initializes the Primary Service Discovery By UUID procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- uuidType – **[in]** Service UUID type.
- pUuid – **[in]** Service UUID.

- aOutPrimaryServices – **[out]** Statically allocated array of gattService_t. The GATT module fills each Service's handle range.
- maxServiceCount – **[in]** Maximum number of services to be filled.
- pOutDiscoveredCount – **[out]** The actual number of services discovered.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_FindIncludedServices(*deviceId_t* deviceId, *gattService_t* *pIoService, uint8_t maxServiceCount)

Initializes the Find Included Services procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- pIoService – **[inout]** The service within which inclusions should be searched. The GATT module uses the Service's handle range and fills the included Services' handle ranges, UUID types and the UUIDs if they are 16-bit UUIDs.
- maxServiceCount – **[in]** Maximum number of included services to be filled.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_DiscoverAllCharacteristicsOfService(*deviceId_t* deviceId, *gattService_t* *pIoService, uint8_t maxCharacteristicCount)

Initializes the Characteristic Discovery procedure for a given Service.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- pIoService – **[inout]** The service within which characteristics should be searched. The GATT module uses the Characteristic's range.
- maxCharacteristicCount – **[in]** Maximum number of characteristics to be filled.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_DiscoverCharacteristicOfServiceByUuid(*deviceId_t* deviceId, *bleUuidType_t* uuidType, const *bleUuid_t* *pUuid, const *gattService_t* *pService, *gattCharacteristic_t* *aOutCharacteristics, uint8_t maxCharacteristicCount, uint8_t *pOutDiscoveredCount)

Initializes the Characteristic Discovery procedure for a given Service, with a given UUID.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- uuidType – **[in]** Characteristic UUID type.
- pUuid – **[in]** Characteristic UUID.
- pService – **[in]** The service within which characteristics should be searched.
- aOutCharacteristics – **[out]** The allocated array of Characteristics to be filled.
- maxCharacteristicCount – **[in]** Maximum number of characteristics to be filled.
- pOutDiscoveredCount – **[out]** The actual number of characteristics discovered.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_DiscoverAllCharacteristicDescriptors(*deviceId_t* deviceId, *gattCharacteristic_t* *pIoCharacteristic, uint16_t endingHandle, uint8_t maxDescriptorCount)

Initializes the Characteristic Descriptor Discovery procedure for a given Characteristic.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback. The endingHandle parameter should be known by the application if Characteristic Discovery was performed, i.e., if the next Characteristic declaration handle is known, then subtract 1 to obtain the endingHandle for the current Characteristic. If the last handle of the Characteristic is still unknown, set the endingHandle parameter to 0xFFFF.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- pIoCharacteristic – **[inout]** The characteristic within which descriptors should be searched. The GATT module uses the Characteristic's handle and fills each descriptor's handle and UUID.
- endingHandle – **[in]** The last handle of the Characteristic.
- maxDescriptorCount – **[in]** Maximum number of descriptors to be filled.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_ReadCharacteristicValue(*deviceId_t* deviceId, *gattCharacteristic_t* *pIoCharacteristic, uint16_t maxReadBytes)

Initializes the Characteristic Read procedure for a given Characteristic.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- pIoCharacteristic – **[inout]** The characteristic whose value must be read. The GATT module uses the value handle and fills the value and length.
- maxReadBytes – **[in]** Maximum number of bytes to be read.

Return values

- gBleSuccess_c –

- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_ReadUsingCharacteristicUuid(*deviceId_t* deviceId, *bleUuidType_t* uuidType, const *bleUuid_t* *pUuid, const *gattHandleRange_t* *pHandleRange, uint8_t *aOutBuffer, uint16_t maxReadBytes, uint16_t *pOutActualReadBytes)

Initializes the Characteristic Read By UUID procedure.

Remark

This procedure returns the Characteristics found within the specified range with the specified UUID. aOutBuffer will contain the Handle-Value pair length (1 byte), then Handle-Value pairs for all Characteristic Values found with the specified UUID.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- uuidType – **[in]** Characteristic UUID type.
- pUuid – **[in]** Characteristic UUID.
- pHandleRange – **[in]** Handle range for the search or NULL. If this is NULL, the search range is 0x0001-0xffff.
- aOutBuffer – **[out]** The allocated buffer to read into.
- maxReadBytes – **[in]** Maximum number of bytes to be read.
- pOutActualReadBytes – **[out]** The actual number of bytes read.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_ReadMultipleCharacteristicValues(*deviceId_t* deviceId, uint8_t cNumCharacteristics, *gattCharacteristic_t* *aIoCharacteristics)

Initializes the Characteristic Read Multiple procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- aIoCharacteristics – **[inout]** Array of the characteristics whose values are to be read. The GATT module uses each Characteristic's value handle and maxValueLength fills each value and length.
- cNumCharacteristics – **[in]** Number of characteristics in the array.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_WriteCharacteristicValue(*deviceId_t* deviceId, const *gattCharacteristic_t* *pCharacteristic, uint16_t valueLength, const uint8_t *aValue, bool_t withoutResponse, bool_t signedWrite, bool_t doReliableLongCharWrites, const uint8_t *aCsrk)

Initializes the Characteristic Write procedure for a given Characteristic.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- pCharacteristic – **[in]** The characteristic whose value must be written. The GATT module uses the value handle.
- valueLength – **[in]** Number of bytes to be written.
- aValue – **[in]** Array of bytes to be written.
- withoutResponse – **[in]** Indicates if a Write Command is used.
- signedWrite – **[in]** Deprecated parameter.
- doReliableLongCharWrites – **[in]** Indicates Reliable Long Writes.
- aCsrk – **[in]** Deprecated parameter.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleOverflow_c – TX queue for device is full.

- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_ReadCharacteristicDescriptor(*deviceId_t* deviceId, *gattAttribute_t* *pIoDescriptor, uint16_t maxReadBytes)

Initializes the Characteristic Descriptor Read procedure for a given Characteristic Descriptor.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- pIoDescriptor – **[inout]** The characteristic descriptor whose value must be read. The GATT module uses the attribute's handle and fills the attribute's value and length.
- maxReadBytes – **[in]** Maximum number of bytes to be read.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_WriteCharacteristicDescriptor(*deviceId_t* deviceId, const *gattAttribute_t* *pDescriptor, uint16_t valueLength, const uint8_t *aValue)

Initializes the Characteristic Descriptor Write procedure for a given Characteristic Descriptor.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- pDescriptor – **[in]** The characteristic descriptor whose value must be written. The GATT module uses the attribute's handle.
- valueLength – **[in]** Number of bytes to be written.
- aValue – **[in]** Array of bytes to be written.

Return values

- gBleSuccess_c –

- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_ReadMultipleVariableCharacteristicValues(*deviceId_t* deviceId, uint8_t cNumCharacteristics, *gattCharacteristic_t* *pIoCharacteristics)

Initializes the Read Multiple Variable Length Characteristic Values procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- cNumCharacteristics – **[in]** Number of characteristics in the array.
- pIoCharacteristics – **[in]** Pointer to the array of the characteristics whose values are to be read.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_RegisterEnhancedProcedureCallback(*gattClientEnhancedProcedureCallback_t* callback)

Installs the application callback for the GATT Client module Procedures on Enhanced ATT bearers.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_RegisterEnhancedNotificationCallback(*gattClientEnhancedNotificationCallback_t* callback)

Installs the application callback for Server Notifications.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_RegisterEnhancedIndicationCallback(*gattClientEnhancedIndicationCallback_t* callback)

Installs the application callback for Server Indications.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_RegisterEnhancedMultipleValueNotificationCallback(*gattClientEnhancedMultipleValueNotific* callback)

Installs the application callback for Server Multiple Value Notification.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedDiscoverAllPrimaryServices(*deviceId_t* deviceId, *bearerId_t* bearerId, *gattService_t* *aOutPrimaryServices, uint8_t maxServiceCount, uint8_t *pOutDiscoveredCount)

Initializes the Primary Service Discovery procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- aOutPrimaryServices – **[out]** Statically allocated array of gattService_t. The GATT module fills each Service's handle range and UUID.
- maxServiceCount – **[in]** Maximum number of services to be filled.
- pOutDiscoveredCount – **[out]** The actual number of services discovered.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedDiscoverPrimaryServicesByUuid(*deviceId_t* deviceId, *bearerId_t* bearerId, *bleUuidType_t* uuidType, const *bleUuid_t* *pUuid, *gattService_t* *aOutPrimaryServices, uint8_t maxServiceCount, uint8_t *pOutDiscoveredCount)

Initializes the Primary Service Discovery By UUID procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- uuidType – **[in]** Service UUID type.
- pUuid – **[in]** Service UUID.

- aOutPrimaryServices – **[out]** Statically allocated array of gattService_t. The GATT module fills each Service's handle range.
- maxServiceCount – **[in]** Maximum number of services to be filled.
- pOutDiscoveredCount – **[out]** The actual number of services discovered.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedFindIncludedServices(*deviceId_t* deviceId, *bearerId_t* bearerId, *gattService_t* *pIoService, uint8_t maxServiceCount)

Initializes the Find Included Services procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- pIoService – **[inout]** The service within which inclusions should be searched. The GATT module uses the Service's handle range and fills the included Services' handle ranges, UUID types and the UUIDs if they are 16-bit UUIDs.
- maxServiceCount – **[in]** Maximum number of included services to be filled.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedDiscoverAllCharacteristicsOfService(*deviceId_t* deviceId, *bearerId_t* bearerId, *gattService_t* *pIoService, uint8_t maxCharacteristicCount)

Initializes the Characteristic Discovery procedure for a given Service.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- pIoService – **[inout]** The service within which characteristics should be searched. The GATT module uses the Characteristic's range.
- maxCharacteristicCount – **[in]** Maximum number of characteristics to be filled.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedDiscoverCharacteristicOfServiceByUuid(*deviceId_t* deviceId, *bearerId_t* bearerId, *bleUuidType_t* uuidType, const *bleUuid_t* *pUuid, const *gattService_t* *pService, *gattCharacteristic_t* *aOutCharacteristics, uint8_t maxCharacteristicCount, uint8_t *pOutDiscoveredCount)

Initializes the Characteristic Discovery procedure for a given Service, with a given UUID.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- uuidType – **[in]** Characteristic UUID type.
- pUuid – **[in]** Characteristic UUID.
- pService – **[in]** The service within which characteristics should be searched.
- aOutCharacteristics – **[out]** The allocated array of Characteristics to be filled.
- maxCharacteristicCount – **[in]** Maximum number of characteristics to be filled.

- pOutDiscoveredCount – **[out]** The actual number of characteristics discovered.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedDiscoverAllCharacteristicDescriptors(*deviceId_t* deviceId, *bearerId_t* bearerId, *gattCharacteristic_t* *pIoCharacteristic, uint16_t endingHandle, uint8_t maxDescriptorCount)

Initializes the Characteristic Descriptor Discovery procedure for a given Characteristic.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback. The endingHandle parameter should be known by the application if Characteristic Discovery was performed, i.e., if the next Characteristic declaration handle is known, then subtract 1 to obtain the endingHandle for the current Characteristic. If the last handle of the Characteristic is still unknown, set the endingHandle parameter to 0xFFFF.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- pIoCharacteristic – **[inout]** The characteristic within which descriptors should be searched. The GATT module uses the Characteristic's handle and fills each descriptor's handle and UUID.
- endingHandle – **[in]** The last handle of the Characteristic.
- maxDescriptorCount – **[in]** Maximum number of descriptors to be filled.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedReadCharacteristicValue(*deviceId_t* deviceId, *bearerId_t* bearerId, *gattCharacteristic_t* *pIoCharacteristic, uint16_t maxReadBytes)

Initializes the Characteristic Read procedure for a given Characteristic.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- pIoCharacteristic – **[inout]** The characteristic whose value must be read. The GATT module uses the value handle and fills the value and length.
- maxReadBytes – **[in]** Maximum number of bytes to be read.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedReadUsingCharacteristicUuid(*deviceId_t* deviceId, *bearerId_t* bearerId, *bleUuidType_t* uuidType, const *bleUuid_t* *pUuid, const *gattHandleRange_t* *pHandleRange, uint8_t *aOutBuffer, uint16_t maxReadBytes, uint16_t *pOutActualReadBytes)

Initializes the Characteristic Read By UUID procedure.

Remark

This procedure returns the Characteristics found within the specified range with the specified UUID. aOutBuffer will contain the Handle-Value pair length (1 byte), then Handle-Value pairs for all Characteristic Values found with the specified UUID.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- uuidType – **[in]** Characteristic UUID type.
- pUuid – **[in]** Characteristic UUID.
- pHandleRange – **[in]** Handle range for the search or NULL. If this is NULL, the search range is 0x0001-0xffff.

- aOutBuffer – **[out]** The allocated buffer to read into.
- maxReadBytes – **[in]** Maximum number of bytes to be read.
- pOutActualReadBytes – **[out]** The actual number of bytes read.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedReadMultipleCharacteristicValues(*deviceId_t* deviceId, *bearerId_t* bearerId, uint8_t cNumCharacteristics, *gattCharacteristic_t* *aIoCharacteristics)

Initializes the Characteristic Read Multiple procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- aIoCharacteristics – **[inout]** Array of the characteristics whose values are to be read. The GATT module uses each Characteristic's value handle and maxValueLength fills each value and length.
- cNumCharacteristics – **[in]** Number of characteristics in the array.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedWriteCharacteristicValue(*deviceId_t* deviceId, *bearerId_t* bearerId, const *gattCharacteristic_t* *pCharacteristic, uint16_t valueLength, const uint8_t *aValue, bool_t withoutResponse, bool_t doReliableLongCharWrites, const uint8_t *aCsrk)

Initializes the Characteristic Write procedure for a given Characteristic.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- pCharacteristic – **[in]** The characteristic whose value must be written. The GATT module uses the value handle.
- valueLength – **[in]** Number of bytes to be written.
- aValue – **[in]** Array of bytes to be written.
- withoutResponse – **[in]** Indicates if a Write Command is used.
- signedWrite – **[in]** Deprecated parameter.
- doReliableLongCharWrites – **[in]** Indicates Reliable Long Writes.
- aCsrk – **[in]** Deprecated parameter.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOverflow_c – TX queue for device is full.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedReadCharacteristicDescriptor(*deviceId_t* deviceId, *bearerId_t* bearerId, *gattAttribute_t* *pIoDescriptor, uint16_t maxReadBytes)

Initializes the Characteristic Descriptor Read procedure for a given Characteristic Descriptor.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- pIoDescriptor – **[inout]** The characteristic descriptor whose value must be read. The GATT module uses the attribute's handle and fills the attribute's value and length.
- maxReadBytes – **[in]** Maximum number of bytes to be read.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedWriteCharacteristicDescriptor(*deviceId_t* deviceId, *bearerId_t* bearerId, const *gattAttribute_t* *pDescriptor, uint16_t valueLength, const uint8_t *aValue)

Initializes the Characteristic Descriptor Write procedure for a given Characteristic Descriptor.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- pDescriptor – **[in]** The characteristic descriptor whose value must be written. The GATT module uses the attribute's handle.
- valueLength – **[in]** Number of bytes to be written.
- aValue – **[in]** Array of bytes to be written.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

bleResult_t GattClient_EnhancedReadMultipleVariableCharacteristicValues(*deviceId_t* deviceId, *bearerId_t* bearerId, uint8_t cNumCharacteristics, *gattCharacteristic_t* *pIoCharacteristics)

Initializes the Read Multiple Variable Length Characteristic Values procedure.

Remark

If gBleSuccess_c is returned, the completion of this procedure is signaled by the Client Enhanced Procedure callback.

Parameters

- deviceId – **[in]** Device ID of the connected peer.
- bearerId – **[in]** Enhanced ATT bearer ID of the connected peer.
- cNumCharacteristics – **[in]** Number of characteristics in the array.
- pIoCharacteristics – **[in]** Pointer to the array of the characteristics whose values are to be read.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

GattClient_SimpleCharacteristicWrite(deviceId, pChar, valueLength, aValue)

Executes the basic Characteristic Write operation (with server confirmation).

Parameters

- deviceId – **[in]** Device ID of the connected GATT Server.
- pChar – **[in]** Pointer to the Characteristic being written.
- valueLength – **[in]** Size in bytes of the value to be written.
- aValue – **[in]** Array of bytes to be written.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOverflow_c – TX queue for device is full.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

GattClient_CharacteristicWriteWithoutResponse(deviceId, pChar, valueLength, aValue)

Executes the Characteristic Write Without Response operation.

Parameters

- deviceId – **[in]** Device ID of the connected GATT Server.
- pChar – **[in]** Pointer to the Characteristic being written.
- valueLength – **[in]** Size in bytes of the value to be written.
- aValue – **[in]** Array of bytes to be written.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOverflow_c – TX queue for device is full.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT client support.

GATT Server

enum gattServerEventType_t

GATT Server Event type enumeration

Values:

enumerator gEvtMtuChanged_c

ATT_MTU was changed after the MTU exchange.

enumerator gEvtHandleValueConfirmation_c

Received a Handle Value Confirmation from the Client.

enumerator gEvtAttributeWritten_c

An attribute registered with GattServer_RegisterHandlesForWriteNotifications was written. After receiving this event, application must call GattServer_SendAttributeWrittenStatus. Application must write the Attribute in the Database if it considers necessary.

enumerator gEvtCharacteristicCccdWritten_c

A CCCD was written. Application should save the CCCD value with Gap_SaveCccd.

enumerator gEvtAttributeWrittenWithoutResponse_c

An attribute registered with GattServer_RegisterHandlesForWriteNotifications was written without response (with ATT Write Command). Application must write the Attribute Value in the Database if it considers necessary.

enumerator gEvtError_c

An error appeared during a Server-initiated procedure.

enumerator gEvtLongCharacteristicWritten_c

A long characteristic was written.

enumerator gEvtAttributeRead_c

An attribute registered with GattServer_RegisterHandlesForReadNotifications is being read. After receiving this event, application must call GattServer_SendAttributeReadStatus.

enumerator gEvtInvalidPduReceived_c

An invalid PDU was received from Client. Application decides if disconnection is required

enum gattServerProcedureType_t

Server-initiated procedure type enumeration

Values:

enumerator gSendAttributeWrittenStatus_c

Procedure initiated by GattServer_SendAttributeWrittenStatus.

enumerator gSendAttributeReadStatus_c

Procedure initiated by GattServer_SendAttributeReadStatus.

enumerator gSendNotification_c

Procedure initiated by GattServer_SendNotification.

enumerator gSendIndication_c

Procedure initiated by GattServer_SendIndication.

enumerator gSendMultipleValNotification_c

Procedure initiated by GattServer_SendMultipleHandleValueNotification.

typedef void (*gattServerCallback_t)(*deviceId_t* deviceId, *gattServerEvent_t* *pServerEvent)

GATT Server Callback prototype

typedef void (*gattServerEnhancedCallback_t)(*deviceId_t* deviceId, *bearerId_t* bearerId, *gattServerEvent_t* *pServerEvent)

GATT Server Enhanced Callback prototype

bleResult_t GattServer_Init(void)

Initializes the GATT Server module.

Remark

Application does not need to call this function if *Gatt_Init()* is called.

Remark

This function executes synchronously.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_RegisterCallback(*gattServerCallback_t* callback)

Installs an application callback for the GATT Server module.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application-defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_RegisterHandlesForWriteNotifications(uint8_t handleCount, const uint16_t *aAttributeHandles)

Registers the attribute handles that will be notified through the GATT Server callback when a GATT Client attempts to modify the attributes' values.

Remark

The application is responsible for actually writing the new requested values in the GATT database. Service and profile-specific control-point characteristics should have their value handles in this list so that the application may get notified when a GATT Client writes it.

Remark

This function executes synchronously.

Parameters

- handleCount – **[in]** Number of handles in array.
- aAttributeHandles – **[in]** Array of handles.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOverflow_c – The maximum number of supported handles for write notifications has been reached.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_UnregisterHandlesForWriteNotifications(uint8_t handleCount, const uint16_t *aAttributeHandles)

Unregisters the attribute handles that will be notified through the GATT Server callback when a GATT Client attempts to modify the attributes' values.

Remark

To unregister all the list, pass 0 count and NULL.

Remark

This function executes synchronously.

Parameters

- handleCount – **[in]** Number of handles in array.
- aAttributeHandles – **[in]** Array of handles.

Return values

- gBleSuccess_c –

- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_SendAttributeWrittenStatus(*deviceId_t* deviceId, uint16_t attributeHandle, uint8_t status)

Responds to an intercepted attribute write operation.

Remark

This function must be called by the application when receiving the gEvtAttributeWritten_c Server event. The status value may contain application- or profile-defined error codes.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- attributeHandle – **[in]** The attribute handle that was written.
- status – **[in]** The status of the write operation. If this parameter is equal to gAttErrCodeNoError_c then an ATT Write Response will be sent to the peer. Otherwise, an ATT Error Response with the provided status will be sent to the peer.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_RegisterHandlesForReadNotifications(uint8_t handleCount, const uint16_t *aAttributeHandles)

Registers the attribute handles that will be notified through the GATT Server callback when a GATT Client attempts to read the attributes' values.

Remark

The application may modify the attribute's value in the GATT Database before sending the response with GattServer_SendAttributeReadStatus.

Remark

This function executes synchronously.

Parameters

- handleCount – **[in]** Number of handles in array.
- aAttributeHandles – **[in]** Array of handles.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleOverflow_c – The maximum number of supported handles for read notifications has been reached.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_UnregisterHandlesForReadNotifications(uint8_t handleCount, const uint16_t *aAttributeHandles)

Unregisters the attribute handles that will be notified through the GATT Server callback when a GATT Client attempts to read the attributes' values.

Remark

To unregister all the list, pass 0 count and NULL.

Remark

This function executes synchronously.

Parameters

- handleCount – **[in]** Number of handles in array.
- aAttributeHandles – **[in]** Array of handles.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_SendAttributeReadStatus(*deviceId_t* deviceId, uint16_t attributeHandle, uint8_t status)

Responds to an intercepted attribute read operation.

Remark

This function must be called by the application when receiving the gEvtAttributeRead_c Server event. The status value may contain application- or profile-defined error codes.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- attributeHandle – **[in]** The attribute handle that was being read.

- status – **[in]** The status of the read operation. If this parameter is equal to gAttErrCodeNoError_c then an ATT Read Response will be sent to the peer containing the attribute value from the GATT Database. Otherwise, an ATT Error Response with the provided status will be sent to the peer.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_SendNotification(*deviceId_t* deviceId, uint16_t handle)

Sends a notification to a peer GATT Client using the Characteristic Value from the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- handle – **[in]** Handle of the Value of the Characteristic to be notified.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_SendIndication(*deviceId_t* deviceId, uint16_t handle)

Sends an indication to a peer GATT Client using the Characteristic Value from the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- handle – **[in]** Handle of the Value of the Characteristic to be indicated.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_SendInstantValueNotification(*deviceId_t* deviceId, uint16_t handle, uint16_t valueLength, const uint8_t *aValue)

Sends a notification to a peer GATT Client with data given as parameter, ignoring the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- handle – **[in]** Handle of the Value of the Characteristic to be notified.
- valueLength – **[in]** Length of data to be notified.

- aValue – **[in]** Data to be notified.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOverflow_c – TX queue for device is full.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_SendMultipleHandleValueNotification(*deviceId_t* deviceId, uint32_t totalLength, const uint8_t *pHandleLengthValueList)

Sends a notification to a peer GATT Client with data given as parameter, ignoring the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- totalLength – **[in]** Length of the handle, value, value length tuples.
- pHandleLengthValueList – **[in]** Pointer to data to be notified.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_SendInstantValueIndication(*deviceId_t* deviceId, uint16_t handle, uint16_t valueLength, const uint8_t *aValue)

Sends an indication to a peer GATT Client with data given as parameter, ignoring the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- handle – **[in]** Handle of the Value of the Characteristic to be indicated.
- valueLength – **[in]** Length of data to be indicated.
- aValue – **[in]** Data to be indicated.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleOverflow_c – TX queue for device is full.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_RegisterUniqueHandlesForNotifications(bool_t bWrite, bool_t bRead)

Registers all GATT DB dynamic attribute handles with unique value buffers to be notified through the GATT Server callback when a GATT Client attempts to read/write the attributes' values.

Remark

This function executes synchronously.

Remark

This function should be called when adding GATT DB unique value buffer characteristics or descriptors.

Parameters

- bWrite – **[in]** Enables/Disables write notifications.
- bRead – **[in]** Enables/Disables read notifications.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_RegisterEnhancedCallback(*gattServerEnhancedCallback_t* callback)

Installs an application callback for the Enhanced ATT GATT Server module.

Remark

This function executes synchronously.

Parameters

- callback – **[in]** Application-defined callback to be triggered by this module.

Return values

- gBleSuccess_c –
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_EnhancedSendAttributeWrittenStatus(*deviceId_t* deviceId, *bearerId_t* bearerId, uint16_t attributeHandle, uint8_t status)

Responds to an intercepted attribute write operation.

Remark

This function must be called by the application when receiving the gEvtAttributeWritten_c Server event. The status value may contain application- or profile-defined error codes.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- bearerId – **[in]** The Enhanced ATT bearer ID of the connected peer.
- attributeHandle – **[in]** The attribute handle that was written.
- status – **[in]** The status of the write operation. If this parameter is equal to gAttErrCodeNoError_c then an ATT Write Response will be sent to the peer. Else an ATT Error Response with the provided status will be sent to the peer.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_EnhancedSendAttributeReadStatus(*deviceId_t* deviceId, *bearerId_t* bearerId, uint16_t attributeHandle, uint8_t status)

Responds to an intercepted attribute read operation.

Remark

This function must be called by the application when receiving the gEvtAttributeRead_c Server event. The status value may contain application- or profile-defined error codes.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- bearerId – **[in]** The Enhanced ATT bearer ID of the connected peer.
- attributeHandle – **[in]** The attribute handle that was being read.
- status – **[in]** The status of the read operation. If this parameter is equal to gAttErrCodeNoError_c then an ATT Read Response will be sent to the peer containing the attribute value from the GATT Database. Else an ATT Error Response with the provided status will be sent to the peer.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_EnhancedSendNotification(*deviceId_t* deviceId, *bearerId_t* bearerId, uint16_t handle)

Sends a notification to a peer GATT Client using the Characteristic Value from the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- bearerId – **[in]** The Enhanced ATT bearer ID of the connected peer.
- handle – **[in]** Handle of the Value of the Characteristic to be notified.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_EnhancedSendIndication(*deviceId_t* deviceId, *bearerId_t* bearerId, uint16_t handle)

Sends an indication to a peer GATT Client using the Characteristic Value from the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- bearerId – **[in]** The Enhanced ATT bearer ID of the connected peer.
- handle – **[in]** Handle of the Value of the Characteristic to be indicated.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_EnhancedSendInstantValueNotification(*deviceId_t* deviceId, *bearerId_t* bearerId, uint16_t handle, uint16_t valueLength, const uint8_t *aValue)

Sends a notification to a peer GATT Client with data given as parameter, ignoring the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- bearerId – **[in]** The Enhanced ATT bearer ID of the connected peer.
- handle – **[in]** Handle of the Value of the Characteristic to be notified.
- valueLength – **[in]** Length of data to be notified.
- aValue – **[in]** Data to be notified.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.

- gBleOverflow_c – TX queue for device is full.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_EnhancedSendMultipleHandleValueNotification(*deviceId_t* deviceId, *bearerId_t* bearerId, uint32_t totalLength, const uint8_t *pHandleLengthValueList)

Sends a notification to a peer GATT Client with data given as parameter, ignoring the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- bearerId – **[in]** The Enhanced ATT bearer ID of the connected peer.
- totalLength – **[in]** Length of the handle, value, value length tuples.
- pHandleLengthValueList – **[in]** Pointer to data to be notified.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

bleResult_t GattServer_EnhancedSendInstantValueIndication(*deviceId_t* deviceId, *bearerId_t* bearerId, uint16_t handle, uint16_t valueLength, const uint8_t *aValue)

Sends an indication to a peer GATT Client with data given as parameter, ignoring the GATT Database.

Parameters

- deviceId – **[in]** The device ID of the connected peer.
- bearerId – **[in]** The Enhanced ATT bearer ID of the connected peer.
- handle – **[in]** Handle of the Value of the Characteristic to be indicated.
- valueLength – **[in]** Length of data to be indicated.
- aValue – **[in]** Data to be indicated.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – An invalid parameter was provided.
- gBleOverflow_c – TX queue for device is full.
- gBleOutOfMemory_c – Could not allocate message for Host task.
- gBleFeatureNotSupported_c – Host library was compiled without GATT server support.

struct gattServerMtuChangedEvent_t

#include <gatt_server_interface.h> GATT Server MTU Changed Event structure

Public Members

uint16_t newMtu
Value of the agreed ATT_MTU for this connection.

struct gattServerAttributeWrittenEvent_t
#include <gatt_server_interface.h> GATT Server Attribute Written Event structure

Public Members

uint16_t handle
Handle of the attribute.

uint16_t cValueLength
Length of the attribute value array.

uint8_t *aValue
Attribute value array attempted to be written.

bearerId_t bearerId
Used by EATT. Send response on the same bearer. For ATT value is 0.

struct gattServerLongCharacteristicWrittenEvent_t
#include <gatt_server_interface.h> GATT Server Long Characteristic Written Event structure

Public Members

uint16_t handle
Handle of the Characteristic Value.

uint16_t cValueLength
Length of the value written.

uint8_t *aValue
Pointer to the attribute value in the database.

struct gattServerCccdWrittenEvent_t
#include <gatt_server_interface.h> GATT Server CCCD Written Event structure

Public Members

uint16_t handle
Handle of the CCCD attribute.

gattCccdFlags_t newCccd
New value of the CCCD.

struct gattServerAttributeReadEvent_t

#include <gatt_server_interface.h> GATT Server Attribute Read Event structure

Public Members

uint16_t handle

Handle of the attribute.

struct gattServerProcedureError_t

#include <gatt_server_interface.h> Server-initiated procedure error structure

Public Members

gattServerProcedureType_t procedureType

Procedure that generated error.

bleResult_t error

Error generated.

struct gattServerInvalidPdu_t

#include <gatt_server_interface.h> ATT PDU that generated the error

Public Members

attOpcode_t attOpCode

The invalid ATT op code that generated the error

struct gattServerEvent_t

#include <gatt_server_interface.h> GATT Server Event structure: type + data.

Public Members

gattServerEventType_t eventType

Event type.

union *gattServerEvent_t* eventData

Event data : selected according to event type.

union eventData

Public Members

gattServerMtuChangedEvent_t mtuChangedEvent

For event type gEvtMtuChanged_c: the new value of the ATT_MTU.

gattServerAttributeWrittenEvent_t attributeWrittenEvent

For event types gEvtAttributeWritten_c, gEvtAttributeWrittenWithoutResponse_c: handle and value of the attempted write.

gattServerCccdWrittenEvent_t charCccdWrittenEvent

For event type gEvtCharacteristicCccdWritten_c: handle and value of the CCCD.

gattServerProcedureError_t procedureError

For event type gEvtError_c: error that terminated a Server-initiated procedure.

gattServerLongCharacteristicWrittenEvent_t longCharWrittenEvent

For event type gEvtLongCharacteristicWritten_c: handle and value.

gattServerAttributeReadEvent_t attributeReadEvent

For event types gEvtAttributeRead_c: handle of the attempted read.

gattServerInvalidPdu_t attributeOpCode

For event type gEvtInvalidPduReceived_c: the ATT PDU that generated the error

GATT Database

enum gattCharacteristicPropertiesBitFields_tag

Values:

enumerator gGattCharPropNone_c

No Properties selected.

enumerator gGattCharPropBroadcast_c

Characteristic can be broadcast.

enumerator gGattCharPropRead_c

Characteristic can be read.

enumerator gGattCharPropWriteWithoutRsp_c

Characteristic can be written without response.

enumerator gGattCharPropWrite_c

Characteristic can be written with response.

enumerator gGattCharPropNotify_c

Characteristic can be notified.

enumerator gGattCharPropIndicate_c

Characteristic can be indicated.

enumerator gGattCharPropAuthSignedWrites_c
Deprecated. Not used.

enumerator gGattCharPropExtendedProperties_c
Extended Characteristic properties.

enum gattDbAccessType_t
Attribute access type

Values:

enumerator gAccessRead_c

enumerator gAccessWrite_c

enumerator gAccessNotify_c

typedef uint8_t gattCharacteristicPropertiesBitFields_t
Bit fields for Characteristic properties

typedef uint8_t gattAttributePermissionsBitFields_t
Bit fields for attribute permissions

uint16_t gGattDbAttributeCount_c
The number of attributes in the GATT Database.

gattDbAttribute_t *gattDatabase
Reference to the GATT database

uint16_t mServerServiceChangedCharHandle

uint16_t mServerServiceChangedCCCDHandle

uint32_t gGattDynamicAttrSize

uint8_t gaGattDynamicAttrBlob[]

uint32_t gGattDynamicValSize

uint8_t gaGattDynamicValBlob[]

uint16_t GattDb_GetIndexOfHandle(uint16_t handle)
Returns the database index for a given attribute handle.

Parameters

- handle – **[in]** The attribute handle.

Returns
The index of the given attribute in the database or gGattDbInvalidHandleIndex_d.

uint16_t GattDb_ServiceStartHandle(uint16_t handle)

Returns the handle of the service to which the given attribute belongs.

Parameters

- handle – **[in]** The attribute handle.

Returns

The handle of the service or gGattDbInvalidHandleIndex_d.

bleResult_t GattDb_FindServiceRange(uint16_t serviceHandle, uint16_t *pOutStartIndex, uint16_t *pOutAttributeCount)

Finds the start index and attribute count for a given service.

Parameters

- serviceHandle – **[in]** The service handle.
- pOutStartIndex – **[in]** The index in the database where the service declaration begins.
- pOutAttributeCount – **[in]** The number of attributes contained by the service.

Return values

- gBleSuccess_c –
- gGattDbInvalidHandleIndex_d – Service does not exist in gatt database.

uint16_t GattDb_GetAttributeValueSize(uint16_t handle)

Returns the value length for a given attribute handle.

Parameters

- handle – **[in]** The attribute handle.

Returns

The length of the value of the attribute at the given handle or maxVariableValueLength in case of variable length attributes.

bleResult_t GattDb_ComputeDatabaseHash(void)

Computes the database hash for a static or a dynamic database.

Parameters

- void. –

Return values

- gBleSuccess_c –
- gBleInvalidState_c – Database not initialized or empty.
- gBleOutOfMemory_c – Could not allocate memory for the database content used to compute the database hash.
- gGattDbInvalidHandleIndex_d – Service does not exist in gatt database.

bleResult_t GattDb_Init(void)

Initializes the GATT database at runtime.

Remark

This function should be called only once at device start-up. In the current stack implementation, it is called internally by Ble_HostInitialize.

Remark

This function executes synchronously.

Return values

- gBleSuccess_c –
- gBleOutOfMemory_c – Could not allocate memory for the GATT dynamic database.
- gBleAlreadyInitialized_c – GATT database already initialized.

bleResult_t GattDb_Deinit(void)

Function performing runtime deinitialization of the GATT database.

Remark

This function has effect for dynamic data base only .

Parameters

- none. –

Return values

- gBleSuccess_c –
- gBleInvalidState_c – GATT dynamic database not initialized.

bleResult_t GattDb_WriteAttribute(uint16_t handle, uint16_t valueLength, const uint8_t *aValue)

Writes an attribute from the application level.

This function can be called by the application code to modify an attribute in the database. It should only be used by the application to modify a Characteristic's value based on the application logic (e.g., external sensor readings).

Remark

This function executes synchronously.

Parameters

- handle – **[in]** The handle of the attribute to be written.
- valueLength – **[in]** The number of bytes to be written.
- aValue – **[in]** The source buffer containing the value to be written.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – aValue NULL and length higher than 0.
- gAttStatusBase_c – + gAttErrCodeInvalidHandle_c handle not found in GATT database.

- gGattInvalidValueLength_c – valueLength not equal to attribute value length, or higher than the maximum length for variable size attributes.
- gBleFeatureNotSupported_c – GATT Server not enabled.

bleResult_t GattDb_ReadAttribute(uint16_t handle, uint16_t maxBytes, uint8_t *aOutValue, uint16_t *pOutValueLength)

Reads an attribute from the application level.

This function can be called by the application code to read an attribute in the database.

Remark

This function executes synchronously.

Parameters

- handle – **[in]** The handle of the attribute to be read.
- maxBytes – **[in]** The maximum number of bytes to be received.
- aOutValue – **[out]** The pre-allocated buffer ready to receive the bytes.
- pOutValueLength – **[out]** The actual number of bytes received.

Return values

- gBleSuccess_c –
- gBleInvalidParameter_c – aOutValue NULL, pOutValueLength NULL or maxBytes 0.
- gAttStatusBase_c – + gAttErrCodeInvalidHandle_c handle not found in GATT database.
- gBleFeatureNotSupported_c – GATT Server not enabled.

bleResult_t GattDb_FindServiceHandle(uint16_t startHandle, *bleUuidType_t* serviceUuidType, const *bleUuid_t* *pServiceUuid, uint16_t *pOutServiceHandle)

Finds the handle of a Service Declaration with a given UUID inside the database.

Remark

This function executes synchronously.

Remark

The startHandle should be set to 0x0001 when this function is called for the first time. If multiple Services with the same UUID are expected, then after the first successful call the function may be called again with the startHandle equal to the found service handle plus one.

Parameters

- startHandle – **[in]** The handle to start the search. Should be 0x0001 on the first call.

- serviceUuidType – **[in]** Service UUID type.
- pServiceUuid – **[in]** Service UUID.
- pOutServiceHandle – **[out]** Pointer to the service declaration handle to be written.

Return values

- gBleSuccess_c – Service Declaration found, handle written in pOutCharValueHandle.
- gGattDbInvalidHandle_c – Invalid Start Handle.
- gBleInvalidParameter_c – pServiceUuid or pOutServiceHandle NULL.
- gGattDbServiceNotFound_c – Service with given UUID not found.
- gBleFeatureNotSupported_c – GATT Server not enabled.

bleResult_t GattDb_FindCharValueHandleInService(uint16_t serviceHandle, *bleUuidType_t* characteristicUuidType, const *bleUuid_t* *pCharacteristicUuid, uint16_t *pOutCharValueHandle)

Finds the handle of a Characteristic Value with a given UUID inside a Service.

The Service is input by its declaration handle.

Remark

This function executes synchronously.

Parameters

- serviceHandle – **[in]** The handle of the Service declaration.
- characteristicUuidType – **[in]** Characteristic UUID type.
- pCharacteristicUuid – **[in]** Characteristic UUID.
- pOutCharValueHandle – **[out]** Pointer to the characteristic value handle to be written.

Return values

- gBleSuccess_c – Characteristic Value found, handle written in pOutCharValueHandle.
- gGattDbInvalidHandle_c – Handle not found or not a Service declaration.
- gBleInvalidParameter_c – pCharacteristicUuid or pOutCharValueHandle NULL.
- gGattDbCharacteristicNotFound_c – Characteristic Value with given UUID not found.
- gBleFeatureNotSupported_c – GATT Server not enabled.

bleResult_t GattDb_FindCccdHandleForCharValueHandle(uint16_t charValueHandle, uint16_t *pOutCccdHandle)

Finds the handle of a Characteristic's CCCD given the Characteristic's Value handle.

Remark

This function executes synchronously.

Parameters

- charValueHandle – **[in]** The handle of the Service declaration.
- pOutCccdHandle – **[out]** Pointer to the CCCD handle to be written.

Return values

- gBleSuccess_c – CCCD found, handle written in pOutCccdHandle.
- gBleInvalidParameter_c – pOutCccdHandle is NULL.
- gGattDbInvalidHandle_c – Invalid Characteristic Value handle.
- gGattDbCccdNotFound_c – CCCD not found for this Characteristic.
- gBleFeatureNotSupported_c – GATT Server not enabled.

bleResult_t GattDb_FindDescriptorHandleForCharValueHandle(uint16_t charValueHandle, *bleUuidType_t* descriptorUuidType, const *bleUuid_t* *pDescriptorUuid, uint16_t *pOutDescriptorHandle)

Finds the handle of a Characteristic Descriptor given the Characteristic's Value handle and Descriptor's UUID.

Remark

This function executes synchronously.

Parameters

- charValueHandle – **[in]** The handle of the Service declaration.
- descriptorUuidType – **[in]** Descriptor's UUID type.
- pDescriptorUuid – **[in]** Descriptor's UUID.
- pOutDescriptorHandle – **[out]** Pointer to the Descriptor handle to be written.

Return values

- gBleSuccess_c – Descriptor found.
- gBleInvalidParameter_c – pDescriptorUuid or pOutDescriptorHandle are NULL.
- gGattDbInvalidHandle_c – Invalid Characteristic Value handle.
- gGattDbDescriptorNotFound_c – Descriptor not found for this Characteristic.
- gBleFeatureNotSupported_c – GATT Server not enabled.

gGattDbInvalidHandleIndex_d

Special value returned by GattDb_GetIndexOfHandle to signal that an invalid attribute handle was given as parameter.

gGattDbInvalidHandle_d

Special value used to mark an invalid attribute handle. Attribute handles are strictly positive.

gPermissionNone_c

No permissions selected.

gPermissionFlagReadable_c

Attribute can be read.

gPermissionFlagReadWithEncryption_c

Attribute may be read only if link is encrypted.

gPermissionFlagReadWithAuthentication_c

Attribute may be read only by authenticated peers.

gPermissionFlagReadWithAuthorization_c

Attribute may be read only by authorized peers.

gPermissionFlagWritable_c

Attribute can be written.

gPermissionFlagWriteWithEncryption_c

Attribute may be written only if link is encrypted.

gPermissionFlagWriteWithAuthentication_c

Attribute may be written only by authenticated peers.

gPermissionFlagWriteWithAuthorization_c

Attribute may be written only by authorized peers.

gGattDatabaseHashSize_c

struct gattDbAttribute_t

#include <gatt_database.h> Attribute structure

Public Members

uint16_t handle

The attribute handle - cannot be 0x0000. The attribute handles need not be consecutive, but must be strictly increasing.

uint16_t permissions

Attribute permissions as defined by the ATT.

uint32_t uuid

The UUID should be read according to the *gattDbAttribute_t.uuidType* member: for 2-byte and 4-byte UUIDs, this contains the value of the UUID; for 16-byte UUIDs, this is a pointer to the allocated 16-byte array containing the UUID.

uint8_t *pValue
: A pointer to allocated value array.

uint16_t valueLength
: The size of the value array.

uint16_t uuidType
: Identifies the length of the UUID; values interpreted according to the *bleUuidType_t* enumeration.

uint16_t maxVariableValueLength
: The maximum length of the attribute value array; if this is set to 0, then the attribute's length is fixed and cannot be changed.

Bluetooth Low Energy

enum bleResult_tag
: BLE result type - the return value of BLE API functions

Values:

enumerator gBleStatusBase_c
: General status base.

enumerator gBleSuccess_c
: Function executed successfully.

enumerator gBleInvalidParameter_c
: Parameter has an invalid value or is outside the accepted range.

enumerator gBleOverflow_c
: An internal limit is reached.

enumerator gBleUnavailable_c
: A requested parameter is not available.

enumerator gBleFeatureNotSupported_c
: The requested feature is not supported by this stack version.

enumerator gBleOutOfMemory_c
: An internal memory allocation failed.

enumerator gBleAlreadyInitialized_c
: Ble_HostInitialize function is incorrectly called a second time.

enumerator gBleOsError_c
: An error occurred at the OS level.

enumerator gBleUnexpectedError_c
: A "should never get here"-type error occurred.

enumerator gBleInvalidState_c
The requested API cannot be called in the current state.

enumerator gBleTimerError_c
Timer allocation failed.

enumerator gBleReassemblyInProgress_c
HCI Packet reassembly was in progress. The old packet was discarded

enumerator gBleNVMError_c
An error occurred when performing an NVM operation

enumerator gBleRngError_c
error generated by a RNG function call e.g. RNG_GetPseudoRandomNo

enumerator gBleSecLibError_c
error generated by a SecLib function call e.g. SecLib_VerifyBluetoothAh

enumerator gHciStatusBase_c
HCI status base.

enumerator gHciSuccess_c
Alias.

enumerator gHciUnknownHciCommand_c
The HCI Command packet opcode is unknown.

enumerator gHciUnknownConnectionIdentifier_c
The connection does not exist or it is of a wrong type.

enumerator gHciHardwareFailure_c
A failure occurred in the Controller.

enumerator gHciPageTimeout_c
A page timed out based on the Page Timeout parameter.

enumerator gHciAuthenticationFailure_c
Pairing or authentication failed. Possible causes: incorrect PIN or Link Key.

enumerator gHciPinOrKeyMissing_c
Pairing failed because of missing PIN or authentication failed because of missing Key.

enumerator gHciMemoryCapacityExceeded_c
The controller doesn't have enough memory to store new parameters.

enumerator gHciConnectionTimeout_c
The link supervision timeout has expired for a connection or the synchronization timeout has expired for a broadcast.

enumerator gHciConnectionLimitExceeded_c

The maximum number of connections has already been reached.

enumerator gHciSynchronousConnectionLimitToADeviceExceeded_c

The maximum number of synchronous connections has already been reached.

enumerator gHciAclConnectionAlreadyExists_c

A connection to this device already exists.

enumerator gHciCommandDisallowed_c

The controller can't process the command at this time.

enumerator gHciConnectionRejectedDueToLimitedResources_c

The connection was rejected due to limited resources.

enumerator gHciConnectionRejectedDueToSecurityReasons_c

The connection was rejected because the security requirements were not fulfilled.

enumerator gHciConnectionRejectedDueToUnacceptableBdAddr_c

The connection was rejected because the device does not accept the given BD_ADDR. A possible cause is that the device only accepts connections from specific BD_ADDRs.

enumerator gHciConnectionAcceptTimeoutExceeded_c

The connection accept timeout for this connection has been exceeded.

enumerator gHciUnsupportedFeatureOrParameterValue_c

The feature or parameter in the HCI command is not supported.

enumerator gHciInvalidHciCommandParameters_c

At least one of the HCI command parameters is invalid.

enumerator gHciRemoteUserTerminatedConnection_c

The remote device's user terminated the connection or stopped broadcasting.

enumerator gHciRemoteDeviceTerminatedConnectionLowResources_c

The remote device terminated the connection due to low resources.

enumerator gHciRemoteDeviceTerminatedConnectionPowerOff_c

The remote device terminated the connection because it will power off.

enumerator gHciConnectionTerminatedByLocalHost_c

The local device terminated the connection, synchronization with a broadcaster or stopped broadcasting.

enumerator gHciRepeatedAttempts_c

The Controller disallows the authentication or pairing because not enough time has passed since the failed attempt.

enumerator gHciPairingNotAllowed_c

The device does not allow pairing.

enumerator gHciUnknownLpmPdu_c

The Controller has received an unknown LMP code.

enumerator gHciUnsupportedRemoteFeature_c

The remote device doesn't support the feature associated with the issued command, LMP PDU or LL Control PDU.

enumerator gHciScoOffsetRejected_c

The offset requested in the LMP_SCO_LINK_REQ PDU has been rejected.

enumerator gHciScoIntervalRejected_c

The interval requested in the LMP_SCO_LINK_REQ PDU has been rejected.

enumerator gHciScoAirModeRejected_c

The air mode requested in the LMP_SCO_LINK_REQ PDU has been rejected.

enumerator gHciInvalidLpmParameters_c

Some LMP PDU or LL Control PDU parameters were invalid.

enumerator gHciUnspecifiedError_c

No other error code was appropriate.

enumerator gHciUnsupportedLpmParameterValue_c

An LMP PDU or LL Control PDU contains at least one parameter value not supported by the Controller at this time.

enumerator gHciRoleChangeNotAllowed_c

The Controller doesn't allow a role change at this time.

enumerator gHciLLResponseTimeout_c

An LMP transaction failed to respond within the LMP response timeout or an LL transaction failed to respond within the LL response timeout.

enumerator gHciLmpErrorTransactionCollision_c

An LMP transaction or LL procedure has collided with the same transaction or procedure which is already in progress.

enumerator gHciLmpPduNotAllowed_c

A controller sent an LMP PDU with an opcode that isn't allowed.

enumerator gHciEncryptionModeNotAcceptable_c

The requested encryption mode is not allowed at this time.

enumerator gHciLinkKeyCannotBeChanged_c

The link key can't be changed because a fixed unit key is being used.

enumerator gHciRequestedQosNotSupported_c

The requested QoS is not supported.

enumerator gHciInstantPassed_c

An LMP PDU or LL PDU that includes an instant cannot be performed because the instant when this would have occurred has passed.

enumerator gHciPairingWithUnitKeyNotSupported_c

It wasn't possible to pair because a unit key was requested but it is not supported.

enumerator gHciDifferentTransactionCollision_c

An LMP transaction or LL Procedure was started that collides with another one.

enumerator gHciReserved_0x2B_c

enumerator gHciQosNotAcceptableParameter_c

The specified QoS parameters couldn't be accepted at this time.

enumerator gHciQosRejected_c

The specified QoS parameters couldn't be accepted and QoS negotiation should be terminated.

enumerator gHciChannelClassificationNotSupported_c

The Controller can't perform a channel assessment because it isn't supported.

enumerator gHciInsufficientSecurity_c

The HCI command or LMP PDU sent is only possible on an encrypted link.

enumerator gHciParameterOutOfMandatoryRange_c

A parameter value requested is outside the mandatory range of parameters for the given HCI command or LMP PDU. The recipient does not accept that value.

enumerator gHciReserved_0x31_c

enumerator gHciRoleSwitchPending_c

A role switch is pending.

enumerator gHciReserved_0x33_c

enumerator gHciReservedSlotViolation_c

The Synchronous negotiation was terminated with its state set to Reserved Slot Violation.

enumerator gHciRoleSwitchFailed_c

A role switch was attempted but it failed. The original piconet structure is restored.

enumerator gHciExtendedInquiryResponseTooLarge_c

The extended inquiry response, with the requested requirements for FEC, is too large to fit in any of the packet types supported by the Controller.

enumerator gHciSecureSimplePairingNotSupportedByHost_c

The IO capabilities request / response was rejected because the sending Host does not support Secure Simple Pairing even though the receiving Link Manager does.

enumerator gHciHostBusyPairing_c

The Host is busy with another pairing request. Pairing should be retried again later.

enumerator gHciConnectionRejectedDueToNoSuitableChannelFound_c

An appropriate value for the Channel selection operation couldn't be calculated by the Controller.

enumerator gHciControllerBusy_c

The operation was rejected because the Controller was busy.

enumerator gHciUnacceptableConnectionParameters_c

The remote device terminated the connection or rejected a request because of at least one unacceptable connection parameter.

enumerator gHciDirectedAdvertisingTimeout_c

Advertising for a fixed duration completed. For directed advertising, advertising completed without a connection being created.

enumerator gHciConnectionTerminatedDueToMicFailure_c

The connection or the synchronization was terminated because the Message Integrity Check failed.

enumerator gHciConnectionFailedToBeEstablishedOrSyncTimeout_c

The LL initiated a connection / synchronization to periodic advertising but the connection has failed to be established or the LL failed to synchronize with the periodic advertising within 6 periodic advertising events of the first attempt.

enumerator gHciMacConnectionFailed_c

enumerator gHciCoarseClockAdjustmentRejected_c

The Central is unable to make a coarse adjustment to the piconet clock, using the given parameters. It will attempt to move the clock using clock dragging.

enumerator gHciType0SubmapNotDefined_c

The LMP PDU is rejected because the Type 0 submap is not currently defined.

enumerator gHciUnknownAdvertisingIdentifier_c

A command was sent from the Host that should identify an Advertising or Sync handle, but that handle doesn't exist.

enumerator gHciLimitReached_c

The number of operations requested has been reached.

enumerator gHciOperationCancelledByHost_c

A request sent from the Host to the Controller which was still pending has been successfully canceled.

enumerator gHciPacketTooLong_c

An attempt was made to send or receive a packet that exceeds the maximum allowed packet length.

enumerator gHciPacketTooLate_c

Information was provided too late to the Controller.

enumerator gHciPacketTooEarly_c

Information was provided too early to the Controller.

enumerator gHciAlreadyInit_c

HCI has already been initialized.

enumerator gHciInvalidParameter_c

At least one of the HCI command parameters is invalid.

enumerator gHciCallbackNotInstalled_c

Callback was not installed.

enumerator gHciCallbackAlreadyInstalled_c

Callback has already been installed.

enumerator gHciCommandNotSupported_c

The HCI command is not supported.

enumerator gHciEventNotSupported_c

The HCI event is not supported.

enumerator gHciTransportError_c

HCI layer initialization failure. HCI data buffering semaphore allocation error. HCI layer received an unknown packet type. Serial initialization or write failure.

enumerator gCtrlStatusBase_c

Controller status base.

enumerator gCtrlSuccess_c

Alias.

enumerator gL2caStatusBase_c

L2CAP status base.

enumerator gL2caSuccess_c

Alias.

enumerator gL2caAlreadyInit_c

L2CAP has already been initialized.

enumerator gL2caInsufficientResources_c

L2CAP could not allocate resources to perform operations (memory or timers).

enumerator gL2caCallbackNotInstalled_c
Callback was not installed.

enumerator gL2caCallbackAlreadyInstalled_c
Callback has already been installed.

enumerator gL2caLePsmInvalid_c
Invalid LE_PSM value.

enumerator gL2caLePsmAlreadyRegistered_c
LE_PSM has already been registered.

enumerator gL2caLePsmNotRegistered_c
LE_PSM value was not registered.

enumerator gL2caLePsmInsufficientResources_c
No free LE_PSM registration slot was found.

enumerator gL2caChannelInvalid_c
L2CA channel is invalid.

enumerator gL2caChannelClosed_c
L2CA channel is closed.

enumerator gL2caChannelAlreadyConnected_c
L2CA channel is already connected.

enumerator gL2caConnectionParametersRejected_c
Connection parameters were rejected.

enumerator gL2caChannelBusy_c
L2CA channel is busy.

enumerator gL2caInvalidParameter_c
The command contains at least one invalid parameter.

enumerator gL2caInternalError_c
There are connected L2CAP channels for the LE_PSM.

enumerator gSmStatusBase_c
Security Manager status base.

enumerator gSmSuccess_c
Alias.

enumerator gSmNullCBFunction_c

enumerator gSmCommandNotSupported_c

The Security Manager (SM) does not have the required features or version to support this command

enumerator gSmUnexpectedCommand_c

This command is not or cannot be handled in the current context of the SM.

enumerator gSmInvalidCommandCode_c

The provided SM command code is invalid.

enumerator gSmInvalidCommandLength_c

The provided command length is not valid for the SM command code.

enumerator gSmInvalidCommandParameter_c

One of the parameters of the SM command is not valid.

enumerator gSmInvalidDeviceId_c

The provided Device ID is invalid.

enumerator gSmInvalidInternalOperation_c

There is a problem with the internal state of the SM. This should not happen during normal operation. A memory corruption or invalid operation may have occurred.

enumerator gSmInvalidConnectionHandle_c

The target device does not have a valid connection handle. It might be disconnected.

enumerator gSmInproperKeyDistributionField_c

The Responder upper layer has set to “1” one or more flags in the Initiator or Responder Key Distribution Fields from the Pairing Request which were set to “0” by the peer device.

enumerator gSmUnexpectedKeyType_c

The Responder upper layer has set a key type field in the Passkey Request Reply command, which is different than the field negotiated with the peer device.

enumerator gSmUnexpectedPairingTerminationReason_c

The upper layer tried to cancel the pairing procedure with an unexpected pairing failure reason for the current phase of the pairing procedure.

enumerator gSmUnexpectedKeyset_c

The Responder upper layer is trying to distribute keys which were not requested during the pairing procedure or the peer device has sent a Key Distribution packet which was not expected.

enumerator gSmSmpTimeoutOccurred_c

An SMP timeout has occurred for the peer device. No more operations are accepted until a new physical link is established.

enumerator gSmUnknownSmpPacketType_c

An SMP packet with an unknown (or invalid) type has been received.

enumerator gSmInvalidSmpPacketLength_c

An SMP packet with an invalid length for the SMP packet type has been received.

enumerator gSmInvalidSmpPacketParameter_c

An SMP packet with an invalid parameter has been received.

enumerator gSmReceivedUnexpectedSmpPacket_c

An unexpected SMP packet was received.

enumerator gSmReceivedSmpPacketFromUnknownDevice_c

An SMP packet is received but the source Device ID cannot be identified.

enumerator gSmReceivedUnexpectedHciEvent_c

An HCI event has been received which cannot be handled by the SM or cannot be handled in the current context.

enumerator gSmReceivedHciEventFromUnknownDevice_c

An HCI event is received but the source Device ID cannot be identified.

enumerator gSmInvalidHciEventParameter_c

An HCI Event is received with an invalid parameter.

enumerator gSmLlConnectionEncryptionInProgress_c

A Link Layer Connection encryption was requested by the upper layer or attempted internally by the SM, but it could no be completed because an encryption was already in progress. This situation could lead to an SMP Pairing Failure when the SM cannot encrypt the link with the STK. An unspecified pairing failure reason is used in this instance.

enumerator gSmLlConnectionEncryptionFailure_c

The Link Layer connection encryption procedure has failed.

enumerator gSmInsufficientResources_c

The SM could not allocate resources to perform operations (memory or timers).

enumerator gSmOobDataAddressMismatch_c

The address of the peer contained in the remote OOB data sent to the stack does not match the address used by the remote device for the connection/pairing procedure.

enumerator gSmSmpPacketReceivedAfterTimeoutOccurred_c

A SMP packet has been received from a peer device for which a pairing procedure has timed out. No further operations are permitted until a new connection is established.

enumerator gSmReceivedTimerEventForUnknownDevice_c

An Timer event is received but the source Device ID cannot be identified.

enumerator gSmUnattainableLocalDeviceSecRequirements_c

The provided pairing parameters cannot lead to a Pairing Procedure which satisfies the minimum security properties for the local device.

enumerator gSmUnattainableLocalDeviceMinKeySize_c

The provided pairing parameters cannot lead to a Pairing Procedure which satisfies the minimum encryption key size for the local device.

enumerator gSmUnattainablePeripheralSecReqRequirements_c

The provided pairing parameters cannot lead to a Pairing Procedure which satisfies the minimum security properties requested by the local device via an SMP Peripheral Security Request.

enumerator gSmInvalidPeerPublicKey_c

This status covers the case where the peer provides a public key with an identical X coordinate to our own.

enumerator gSmPairingErrorPasskeyEntryFailed_c

The passkey entry failed.

enumerator gSmPairingErrorConfirmValueFailed_c

The received random confirm value does not match the computed random confirm value.

enumerator gSmPairingErrorCommandNotSupported_c

The command is not supported.

enumerator gSmPairingErrorInvalidParameters_c

The command contains at least one invalid parameter.

enumerator gSmPairingErrorUnknownReason_c

Unknown pairing failure reason.

enumerator gSmPairingErrorTimeout_c

The pairing procedure timed out.

enumerator gSmPairingErrorAuthenticationRequirements_c

Authentication requirements were not met.

enumerator gSmPairingAlreadyStarted_c

The pairing process has already started.

enumerator gSmPairingErrorKeyRejected_c

The key was rejected.

enumerator gSmPairingErrorPairingNotSupported_c

Pairing is not supported by the device.

enumerator gSmPairingErrorEncryptionKeySize_c

The resultant encryption key size is not long enough for the security requirements of this device.

enumerator gSmPairingErrorDhKeyCheckFailed_c

DHKey Check value received doesn't match the one calculated by the local device.

enumerator gSmPairingErrorNumericComparisonFailed_c

Indicates that the confirm values in the numeric comparison protocol do not match.

enumerator gSmPairingErrorOobNotAvailable_c

Indicates that the OOB data is not available.

enumerator gSmPairingErrorRepeatedAttempts_c

Indicates that the pairing or authentication procedure is disallowed because too little time has elapsed since last pairing request or security request.

enumerator gSmPairingErrorBusy_c

Indicates that the device is not ready to perform a pairing procedure

enumerator gSmTbResolvableAddressDoesNotMatchIrk_c

The provided Resolvable Private Address and IRK do not match.

enumerator gSmKeySessionKeyDerivationFailed_c

The session key derivation failed.

enumerator gAttStatusBase_c

ATT status base.

enumerator gAttSuccess_c

Alias.

enumerator gGattStatusBase_c

GATT status base.

enumerator gGattSuccess_c

Alias.

enumerator gGattAnotherProcedureInProgress_c

Trying to start a GATT procedure while one is already in progress.

enumerator gGattLongAttributePacketsCorrupted_c

Writing a Long Characteristic failed because Prepare Write Request packets were corrupted.

enumerator gGattMultipleAttributesOverflow_c

Too many Characteristics are given for a Read Multiple Characteristic procedure.

enumerator gGattUnexpectedReadMultipleResponseLength_c

Read Multiple Characteristic procedure failed because unexpectedly long data was read.

enumerator gGattInvalidValueLength_c

An invalid value length was supplied to a Characteristic Read/Write operation.

enumerator gGattServerTimeout_c

No response was received from the Server.

enumerator gGattIndicationAlreadyInProgress_c

A Server Indication is already waiting for Client Confirmation.

enumerator gGattClientConfirmationTimeout_c

No Confirmation was received from the Client after a Server Indication.

enumerator gGattInvalidPduReceived_c

An invalid PDU length was received.

enumerator gGattPeerDisconnected_c

An ongoing GATT procedure could not be finished due to peer's disconnection.

enumerator gGattMtuExchangeInProgress_c

A Server Indication is already waiting for Client Confirmation.

enumerator gGattOutOfSyncProceduresOngoing_c

Client can't read the Database Hash until all pending procedures are done.

enumerator gGattConnectionSecurityRequirementsNotMet_c

Client cannot initiate communication if the device security requirements are not met, e.g., link is not yet encrypted/authenticated.

enumerator gGapStatusBase_c

GAP status base.

enumerator gGapSuccess_c

Alias.

enumerator gGapAdvDataTooLong_c

Trying to set too many bytes in the advertising payload.

enumerator gGapScanRspDataTooLong_c

Trying to set too many bytes in the scan response payload.

enumerator gGapDeviceNotBonded_c

Trying to execute an API that is only available for bonded devices.

enumerator gGapAnotherProcedureInProgress_c

Trying to start a GAP procedure while one is already in progress.

enumerator gDevDbStatusBase_c

DeviceDatabase status base.

enumerator gDevDbSuccess_c

Alias.

enumerator gDevDbCccdLimitReached_c
CCCD value cannot be saved because Server's CCCD list is full for the current client.

enumerator gDevDbCccdNotFound_c
CCCD with the given handle is not found in the Server's list for the current client.

enumerator gGattDbStatusBase_c
GATT Database status base.

enumerator gGattDbSuccess_c
Alias.

enumerator gGattDbInvalidHandle_c
An invalid handle was passed as parameter.

enumerator gGattDbCharacteristicNotFound_c
Characteristic was not found.

enumerator gGattDbCccdNotFound_c
CCCD was not found.

enumerator gGattDbServiceNotFound_c
Service Declaration was not found.

enumerator gGattDbDescriptorNotFound_c
Characteristic Descriptor was not found.

enumerator gGattDbServiceOrCharAlreadyDeclared_c
Service or characteristic already declared

enumerator gCsStatusBase_c
Channel Sounding status base.

enumerator gCsSuccess_c
Alias.

enumerator gCsCallbackAlreadyInstalled_c
The selected callback was already installed.

enumerator gCsSecurityCheckFail_c
GAP Mode 4 security check fail.

enum bearerStatus_tag
Enhanced ATT bearer status values
Values:

enumerator gEattBearerActive_c

enumerator gEattBearerReconfInProgress_c

enumerator gEattBearerSuspended_c

enumerator gEattBearerAllocated_c

enumerator gEattBearerFree_c

enumerator gEattBearerAlreadyAllocated_c

enum bleAdvertisingType_t

Advertising Type

Values:

enumerator gAdvConnectableUndirected_c

Answers to both connect and scan requests.

enumerator gAdvDirectedHighDutyCycle_c

Answers only to connect requests; smaller advertising interval for quicker connection.

enumerator gAdvScannable_c

Answers only to scan requests.

enumerator gAdvNonConnectable_c

Does not answer to connect nor scan requests.

enumerator gAdvDirectedLowDutyCycle_c

Answers only to connect requests; larger advertising interval.

enum bleAdvReportEventProperties_tag

Values:

enumerator gAdvEventConnectable_c

Connectable Advertisement

enumerator gAdvEventScannable_c

Scannable Advertisement

enumerator gAdvEventDirected_c

Directed Advertisement

enumerator gAdvEventScanResponse_c

Scan Response

enumerator gAdvEventLegacy_c

Legacy Advertisement PDU

enumerator gAdvEventAnonymous_c
Anonymous Advertisement

enum bleAdvRequestProperties_tag
Values:

enumerator gAdvReqConnectable_c
Connectable Advertising

enumerator gAdvReqScannable_c
Scannable Advertising

enumerator gAdvReqDirected_c
Directed Advertising

enumerator gAdvReqHighDutyCycle_c
High Duty Cycle

enumerator gAdvReqLegacy_c
Legacy Advertising PDU

enumerator gAdvReqAnonymous_c
Anonymous Advertising

enumerator gAdvIncludeTxPower_c
Set this option to include the Tx power in advertising packet.

enumerator gAdvUseDecisionPDU_c
Use ADV_DECISION_IND PDU(0b1001).

enumerator gAdvIncludeAdvAinDecisionPDU_c
Include AdvA in the extended header of all decision PDUs.

enumerator gAdvIncludeADIinDecisionPDU_c
Include ADI in the extended header of all decision PDUs.

enum bleAdvertisingFilterPolicy_t
Values:

enumerator gBleAdvFilterAllowScanFromAnyAllowConnFromAny_c
Filter Accept List is ignored.

enumerator gBleAdvFilterAllowScanFromWLAllowConnFromAny_c
Filter Accept List is used only for Scan Requests.

enumerator gBleAdvFilterAllowScanFromAnyAllowConnFromWL_c
Filter Accept List is used only for Connection Requests.

enumerator gBleAdvFilterAllowScanFromWLAllowConnFromWL_c
Filter Accept List is used for both Scan and Connection Requests.

enum bleLlConnectionRole_t
Values:

enumerator gBleLlConnectionCentral_c
Link Layer Central Role

enumerator gBleLlConnectionPeripheral_c
Link Layer Peripheral Role

enum gapLeModulationTestMode_t
LE Modulation Test Mode values
Values:

enumerator gLeModulationTestDisable_c
Disable modulation test

enumerator gLeModulationTestUnmodulated_c
Unmodulated signal

enumerator gLeModulationTestModulatedZeros_c
Modulated with 0's

enumerator gLeModulationTestModulatedOnes_c
Modulated with 1's

enumerator gLeModulationTestModulatedPRBS_c
Modulated with pseudo-random

enumerator gLeModulationTestRssiMeasurement_c
RSSI measurement

enum bleCentralClockAccuracy_tag
Values:

enumerator gBleCentralClkAcc500ppm_c

enumerator gBleCentralClkAcc250ppm_c

enumerator gBleCentralClkAcc150ppm_c

enumerator gBleCentralClkAcc100ppm_c

enumerator gBleCentralClkAcc75ppm_c

enumerator gBleCentralClkAcc50ppm_c

enumerator gBleCentralClkAcc30ppm_c

enumerator gBleCentralClkAcc20ppm_c

enum bleAdvertiserClockAccuracy_tag

Values:

enumerator gBleAdvertiserClkAcc500ppm_c

enumerator gBleAdvertiserClkAcc250ppm_c

enumerator gBleAdvertiserClkAcc150ppm_c

enumerator gBleAdvertiserClkAcc100ppm_c

enumerator gBleAdvertiserClkAcc75ppm_c

enumerator gBleAdvertiserClkAcc50ppm_c

enumerator gBleAdvertiserClkAcc30ppm_c

enumerator gBleAdvertiserClkAcc20ppm_c

enum bleAdvertisingReportEventType_t

Values:

enumerator gBleAdvRepAdvInd_c

enumerator gBleAdvRepAdvDirectInd_c

enumerator gBleAdvRepAdvScanInd_c

enumerator gBleAdvRepAdvNonconnInd_c

enumerator gBleAdvRepScanRsp_c

enum hciPacketType_t

Values:

enumerator gHciCommandPacket_c

HCI Command

enumerator gHciDataPacket_c

L2CAP Data Packet

enumerator gHciSynchronousDataPacket_c
Not used in BLE

enumerator gHciEventPacket_c
HCI Event

enumerator gHciIsoDataPacket_c
HCI ISO data packet

enum bleScanType_t
Scanning type enumeration.
Values:

enumerator gScanTypePassive_c
Passive Scanning - advertising packets are immediately reported to the Host.

enumerator gScanTypeActive_c
Active Scanning - the scanner sends scan requests to the advertiser and reports to the Host after the scan response is received.

enum bleTransmitPowerLevelType_t
Values:

enumerator gReadCurrentTxPowerLevel_c
Current TX Power level.

enumerator gReadMaximumTxPowerLevel_c
Maximum recorded TX Power level.

enum bleTransmitPowerChannelType_t
Values:

enumerator gTxPowerAdvChannel_c
Advertising channel type when setting Tx Power.

enumerator gTxPowerConnChannel_c
Connection channel type when setting Tx Power.

enum bleChannelOverrideMode_t
Values:

enumerator gOverrideAdvChannels_c
Set the advertising channels

enumerator gOverrideScanChannels_c
Set the scanning channels

enumerator gOverrideInitChannels_c
Set the connection initiation channels

enum bleChannelFrequency_t

Values:

enumerator gBleFreq2402MHz_c

enumerator gBleFreq2404MHz_c

enumerator gBleFreq2406MHz_c

enumerator gBleFreq2408MHz_c

enumerator gBleFreq2410MHz_c

enumerator gBleFreq2412MHz_c

enumerator gBleFreq2414MHz_c

enumerator gBleFreq2416MHz_c

enumerator gBleFreq2418MHz_c

enumerator gBleFreq2420MHz_c

enumerator gBleFreq2422MHz_c

enumerator gBleFreq2424MHz_c

enumerator gBleFreq2426MHz_c

enumerator gBleFreq2428MHz_c

enumerator gBleFreq2430MHz_c

enumerator gBleFreq2432MHz_c

enumerator gBleFreq2434MHz_c

enumerator gBleFreq2436MHz_c

enumerator gBleFreq2438MHz_c

enumerator gBleFreq2440MHz_c

enumerator gBleFreq2442MHz_c

enumerator gBleFreq2444MHz_c

enumerator gBleFreq2446MHz_c

enumerator gBleFreq2448MHz_c

enumerator gBleFreq2450MHz_c

enumerator gBleFreq2452MHz_c

enumerator gBleFreq2454MHz_c

enumerator gBleFreq2456MHz_c

enumerator gBleFreq2458MHz_c

enumerator gBleFreq2460MHz_c

enumerator gBleFreq2462MHz_c

enumerator gBleFreq2464MHz_c

enumerator gBleFreq2466MHz_c

enumerator gBleFreq2468MHz_c

enumerator gBleFreq2470MHz_c

enumerator gBleFreq2472MHz_c

enumerator gBleFreq2474MHz_c

enumerator gBleFreq2476MHz_c

enumerator gBleFreq2478MHz_c

enumerator gBleFreq2480MHz_c

enum bleTxTestPacketPayload_t

Values:

enumerator gBleTestPacketPayloadPrbs9_c

enumerator gBleTestPacketPayloadPattern11110000_c

enumerator gBleTestPacketPayloadPattern10101010_c

enumerator gBleTestPacketPayloadPrbs15_c

enumerator gBleTestPacketPayloadPatternAllBits1_c

enumerator gBleTestPacketPayloadPatternAllBits0_c

enumerator gBleTestPacketPayloadPattern00001111_c

enumerator gBleTestPacketPayloadPattern01010101_c

enum bleHardwareErrorCode_t

Values:

enumerator bleHwErrCodeNoError_c

enum leSupportedFeatures_tag

Values:

enumerator gLeEncryption_c

enumerator gLeConnectionParametersRequestProcedure_c

enumerator gLeExtendedRejectIndication_c

enumerator gLePeripheralInitiatedFeaturesExchange_c

enumerator gLePing_c

enumerator gLeDataPacketLengthExtension_c

enumerator gLeLlPrivacy_c

enumerator gLeExtendedScannerFilterPolicies_c

enumerator gLe2MbPhy_c

enumerator gLeStableModulationIdxTx_c

enumerator gLeStableModulationIdxRx_c

enumerator gLeCodedPhy_c

enumerator gLeExtendedAdv_c

enumerator gLeConnectionSubrating_c

enumerator gLeConnectionSubratingHostSupport_c

enumerator gAdvertisingCodingSelection_c

enumerator gAdvertisingCodingSelectionHostSupport_c

enumerator gLeDecisionBasedAdvertisingFiltering_c

enumerator gLePawrAdvertiser_c

enumerator gLePawrScanner_c

enumerator gLeChannelSounding_c

enumerator gLeChannelSoundingHostSupport_c

enumerator gLeExtendedFeatures_c

enum leExtendedSupportedFeatures_tag

Values:

enumerator gLeMonitoringAdvertisers_c

enumerator gCsEnhancements1_c

enum gapGenericEventType_t

Generic Event Type

Values:

enumerator gInitializationComplete_c

Initial setup started by Ble_HostInitialize is complete.

enumerator gInternalError_c

An internal error occurred.

enumerator gAdvertisingSetupFailed_c

Error during advertising setup.

enumerator gAdvertisingParametersSetupComplete_c

Advertising parameters have been successfully set. Response to Gap_SetAdvertisingParameters.

enumerator gAdvertisingDataSetupComplete_c

Advertising and/or scan response data has been successfully set. Response to Gap_SetAdvertisingData.

enumerator gFilterAcceptListSizeRead_c

Contains the Filter Accept List size. Response to Gap_ReadFilterAcceptListSize.

enumerator gDeviceAddedToFilterAcceptList_c

Device has been added to Filter Accept List. Response to Gap_AddDeviceToFilterAcceptList.

enumerator gDeviceRemovedFromFilterAcceptList_c

Device has been removed from the Filter Accept List. Response to Gap_RemoveDeviceFromFilterAcceptList.

enumerator gFilterAcceptListCleared_c

Filter Accept List has been cleared. Response to Gap_ClearFilterAcceptList.

enumerator gRandomAddressReady_c

A random device address has been created. Response to Gap_CreateRandomDeviceAddress.

enumerator gCreateConnectionCanceled_c

Connection initiation was successfully cancelled. Response to Gap_CancelInitiatingConnection.

enumerator gPublicAddressRead_c

Contains the public device address. Response to Gap_ReadPublicDeviceAddress.

enumerator gAdvTxPowerLevelRead_c

Contains the TX power on the advertising channel. Response to Gap_ReadAdvertisingTxPowerLevel.

enumerator gPrivateResolvableAddressVerified_c

Contains the result of PRA verification. Response to Gap_VerifyPrivateResolvableAddress.

enumerator gRandomAddressSet_c

Random address has been set into the Controller. Response to Gap_SetRandomAddress.

enumerator gLeScPublicKeyRegenerated_c

The private/public key pair used for LE Secure Connections pairing has been regenerated.

enumerator gLeScLocalOobData_c

Local OOB data used for LE Secure Connections pairing.

enumerator gHostPrivacyStateChanged_c

Host Privacy was enabled or disabled.

enumerator gControllerPrivacyStateChanged_c

Controller Privacy was enabled or disabled.

enumerator gControllerTestEvent_c

Controller Test was started or stopped.

enumerator gTxPowerLevelSetComplete_c

Controller Tx Power Level set complete or invalid.

enumerator gLePhyEvent_c

Phy Mode of a connection has been updated by the Controller.

enumerator gControllerNotificationEvent_c

Controller Enhanced Notification received.

enumerator gGetConnParamsComplete_c

Get Connection Parameters command complete

enumerator gBondCreatedEvent_c

Bond Created Event signalling the stack created a bond after pairing or at app request.

enumerator gChannelMapSet_c

Channel map set complete in the Controller.

enumerator gExtAdvertisingParametersSetupComplete_c

Extended advertising parameters have been successfully set.

enumerator gExtAdvertisingDataSetupComplete_c

Extended advertising data has been successfully set.

enumerator gExtAdvertisingSetRemoveComplete_c

An advertising set has been removed from the Controller.

enumerator gPeriodicAdvParamSetupComplete_c

Periodic advertising parameters have been successfully set.

enumerator gPeriodicAdvDataSetupComplete_c

Periodic advertising data have been successfully set.

enumerator gPeriodicAdvertisingStateChanged_c

Event received when periodic advertising has been successfully enabled or disabled.

enumerator gPeriodicAdvListUpdateComplete_c

Periodic advertiser list has been successfully updated.

enumerator gPeriodicAdvCreateSyncCancelled_c

Periodic advertising create sync command was successfully cancelled

enumerator gTxEntryAvailable_c

This event is generated when a TX entry becomes available after they were all in use.

enumerator gControllerLocalRPARead_c

Contains the resolvable private device address. Response to Gap_ReadControllerLocalRPA.

enumerator gConnectionlessCteTransmitParamsSetupComplete_c

Connectionless CTE transmit parameters have been successfully set.

enumerator gConnectionlessCteTransmitStateChanged_c

Connectionless CTE for an advertising set was enabled or disabled.

enumerator gConnectionlessIqSamplingStateChanged_c

Connectionless CTE IQ sampling for an advertising train was enabled or disabled.

enumerator gAntennaInformationRead_c

Antenna information was read from the controller.

enumerator gModifiedSleepClockAccuracy_c

The Sleep Clock accuracy was changed

enumerator gPeriodicAdvRecvEnableComplete_c

Enable or disable reports for the periodic advertising train command is complete

enumerator gPeriodicAdvSyncTransferComplete_c

The command used to instruct the Controller to send synchronization information about the periodic advertising train identified by the Sync_Handle parameter to a connected device is complete

enumerator gPeriodicAdvSetInfoTransferComplete_c

The command used to instruct the Controller to send synchronization information about the periodic advertising in an advertising set to a connected device is complete

enumerator gSetPeriodicAdvSyncTransferParamsComplete_c

The command specifying how the Controller will process periodic advertising synchronization information is complete

enumerator gSetDefaultPeriodicAdvSyncTransferParamsComplete_c

The command which set the default parameters for periodic advertising synchronization information is complete

enumerator gPeriodicAdvSyncTransferSucceeded_c

Event received when Controller has succeeded the Synchronization to the periodic advertising train

enumerator gPeriodicAdvSyncTransferFailed_c

Event received when Controller has failed the Synchronization to the periodic advertising train

enumerator gConnEvtLeGenerateDhKeyComplete_c

DHKey generation is complete. Key can be found in gapConnectionEvent_t.eventData.leGenerateDhKeyCompleteEvent

enumerator gHandoverGetComplete_c

Handover data get complete.

enumerator gHandoverSetComplete_c

Handover data set complete.

enumerator gHandoverGetCsLlContextComplete_c

Handover CS LL context data get complete.

enumerator gHandoverSetCsLlContextComplete_c

Handover CS LL context data set complete.

enumerator gHandoverGetTime_c

Handover Get Time command complete

enumerator gHandoverSuspendTransmitComplete_c

Handover Suspend Transmit command complete

enumerator gHandoverResumeTransmitComplete_c

Handover Resume Transmit command complete

enumerator gHandoverAnchorNotificationStateChanged_c

Handover Anchor Notification command complete

enumerator gHandoverAnchorSearchStarted_c

Handover Anchor Search Start command complete

enumerator gHandoverAnchorSearchStopped_c

Handover Anchor Search Stop command complete

enumerator gHandoverTimeSyncTransmitStateChanged_c

Handover Time Sync Transmit command complete

enumerator gHandoverTimeSyncReceiveComplete_c

Handover Time Sync Receive command complete

enumerator gHandoverAnchorMonitorEvent_c

Event received from Controller - Handover Anchor Monitor

enumerator gHandoverTimeSyncEvent_c

Event received from Controller - Handover Time Sync

enumerator gHandoverConnParamUpdateEvent_c

Event received from Controller - Handover Conn Params Update

enumerator gRemoteVersionInformationRead_c

Version Information of a peer was read

enumerator gLlSkdReportEvent_c

Session Key Diversifier report

enumerator gLeSetSchedulerPriorityComplete_c

LE Set Scheduler Priority command complete

enumerator gDeInitializationComplete_c

Event received when Ble_HostDeInitialize is complete.

enumerator gHandoverAnchorMonitorPacketEvent_c

Event received from Controller - Handover Anchor Monitor Packet. pPdu must be freed by the application

enumerator gHandoverAnchorMonitorPacketContinueEvent_c

Event received from Controller - Handover Anchor Monitor Packet Continue. pPdu must be freed by the application

enumerator gHandoverFreeComplete_c

Handover data free complete.

enumerator gHandoverUpdateConnParamsComplete_c

Handover Update Connection Parameters command complete

enumerator gExtAdvertisingDecisionDataSetupComplete_c

Extended advertising decision data has been successfully set.

enumerator gDecisionInstructionsSetupComplete_c

decision instructions used when listening for decision advertisements PDUs has been successfully set.

enumerator gHandoverLlPendingData_c

ACL Data pending to be transmited by the LL

enumerator gLeChannelOverrideComplete_c

LE Channel Override command complete

enumerator gPeriodicAdvSetSubeventDataComplete_c

Periodic advertising subevent data has been successfully set.

enumerator gPeriodicAdvSetResponseDataComplete_c

Periodic advertising response data has been successfully set.

enumerator gPeriodicSyncSubeventComplete_c

Set Sync Subevent command successfully completed.

enumerator gHandoverConnectionUpdateProcedureEvent_c

This event is used to report the new connection parameters indicated during the Connection Update procedure

enumerator gHandoverApplyConnectionUpdateProcedureComplete_c

This event is used to report the new connection parameters indicated during the Connection Update procedure

enumerator gVendorUnitaryTestComplete_c

Vendor Unitary Test command complete

enumerator gLeSetDataRelatedAddressChangesComplete_c

Set Data Related Address Changes command complete

enumerator gLePeriodicAdvUpdateSyncComplete_c

Le Periodic Adv Update Sync command complete

enumerator gDeviceAddedToMonAdvList_c

LE Add Device To Monitored Advertisers List command complete

enumerator gDeviceRemovedFromMonAdvList_c

Remove Device From Monitored Advertisers List command complete

enumerator gMonAdvListCleared_c

Clear Monitored Advertisers List command complete

enumerator gMonAdvEnabled_c

Enable Monitoring Advertisers command complete

enumerator gMonAdvListSizeRead_c

Read Monitored Advertisers List Size command complete

enumerator gVendorDebugEvent_c

Vendor specific debugging event signaling NBU fatal error

enumerator gLeSetDefaultConnectionSubrateParametersSetupComplete_c
Default Connection Subrate Parameters.have been successfully set

enumerator gLeChasConfigComplete_c
LE CHAS Config command completed successfully

enumerator gLeModulationTestComplete_c
LE Modulation Test command completed successfully

enum gapInternalErrorSource_t
Internal Error Source - the command that triggered the error
Values:

enumerator gHciCommandStatus_c

enumerator gCheckPrivateResolvableAddress_c

enumerator gAddNewConnection_c

enumerator gResetController_c

enumerator gSetEventMask_c

enumerator gHciRecvFragmentOfPacket_c

enumerator gHciDataDiscardedAlloc_c
A memory allocation failure occurred in the HCI layer. Data was discarded.

enumerator gHciDataDiscardedInvalidStateParam_c
A packet with an invalid parameter or length was received by the HCI layer. Data was discarded.

enumerator gGetConnParams_c
An error occurred during the Get Connection Params procedure

enumerator gHandover_c
An error occurred during the connection handover process

enumerator gHandoverGetLlContext_c
An error occurred during the Handover Get LL Context procedure

enumerator gHandoverConnect_c
An error occurred during the Handover Connect procedure

enumerator gHandoverDisconnect_c
An error occurred during the Handover Disconnect procedure

enumerator gHandoverSetSkd_c
An error occurred during the Handover Set SKD procedure

enumerator gHandoverSuspendTransmitLlProcInProgress_c
Could not suspend transmit at LL level due to an LL procedure being in progress

enumerator gHandoverSuspendTransmitHostTxInProgress_c
Could not suspend transmit at Host level due to ongoing data transfers

enumerator gHandoverGetCsLlContext_c
An error occurred during the Handover Get CS LL Context procedure

enumerator gHandoverSetCsLlContext_c
An error occurred during the Handover Set CS LL Context procedure

enumerator gHandoverUpdateConnParams_c
An error occurred during the Handover Update Connection Parameters procedure

enumerator gLeSetHostFeature_c

enumerator gSetExtAdvDecisionData_c

enumerator gSetDecisionInstructions_c

enumerator gSetExpmSupportedFeatures_c

enumerator gHandoverSuspendTransmitHciTx_c
Could not suspend transmit due to HCI tx error

enumerator gHandoverResumeTransmitHciTx_c
Could not resume transmit due to HCI tx error

enumerator gHandoverAnchorNotifHciTx_c
Could not enable/disable Anchor Notification due to HCI tx error

enumerator gHandoverAnchorSearchStartHciTx_c
Could not start Anchor Search due to HCI tx error

enumerator gHandoverAnchorSearchStopHciTx_c
Could not stop Anchor Search due to HCI tx error

enumerator gHandoverTimeSyncTxHciTx_c
Could not start/stop Anchor Time Sync transmit due to HCI tx error

enumerator gHandoverTimeSyncRxHciTx_c
Could not start/stop Anchor Time Receive transmit due to HCI tx error

enumerator gHandoverSuspendTransmitLl_c
Handover Suspend Transmit Link Layer error

enumerator gHandoverGetTimeLl_c
Handover Get Time Link Layer error

enumerator gHandoverResumeTransmitLl_c
Handover Resume Transmit Link Layer error

enumerator gHandoverAnchorNotifLl_c
Handover Anchor Notification Link Layer error

enumerator gHandoverAnchorSearchStartLl_c
Handover Anchor Search Start Link Layer error

enumerator gHandoverAnchorSearchStopLl_c
Handover Anchor Search Stop Link Layer error

enumerator gHandoverTimeSyncTxLl_c
Handover Time Sync Transmit Link Layer error

enumerator gHandoverTimeSyncRxLl_c
Handover Time Sync Receive Link Layer error

enumerator gHandoverSetLlPendingData_c
Handover Set LL Pending Data error

enumerator gLeChannelOverride_c
LE Channel Override command unsuccessful

enumerator gLeSetPeriodicAdvParamsV2_c

enumerator gLeSetPeriodicAdvSubeventData_c

enumerator gLeSetPeriodicAdvResponseData_c

enumerator gLeSetPeriodicSyncSubevent_c

enumerator gLePeriodicAdvResponseReport_c

enumerator gHandoverApplyConnectionUpdateProcedure_c
An error occurred during the Handover Apply Connection Update procedure

enumerator gVendorUnitaryTest_c
An error occurred during the Vendor Unitary Test procedure

enumerator gSetDataRelatedAddressChanges_c
An error occurred during the Set Data Related Address procedure

enumerator gLePeriodicAdvUpdateSync_c
An error occurred during the Le Periodic Adv Update Sync procedure

enumerator gReadAllLocalSupportedFeatures_c
An error occurred during the LE Read All Local Supported Features command

enumerator gAddDeviceToMonAdvList_c
An error occurred during the Add Device To Monitored Advertisers List

enumerator gRemoveDeviceFromMonAdvList_c
An error occurred during the Remove Device From Monitored Advertisers List

enumerator gClearMonAdvList_c
An error occurred during the Clear Monitored Advertisers List

enumerator gEnableMonAdv_c
An error occurred during the Enable Monitoring Advertisers

enumerator gReadMonAdvListSize_c
An error occurred during the Read Monitored Advertisers List Size

enumerator gSetDefaultConnectionSubrateParameters_c
An error occurred while setting the Default Connection Subrate Parameters

enumerator gConnectionSubrateRequest_c
An error occurred during the Connection Subrate procedure

enumerator gEncryptLinkTak_c
An error occurred during Encrypt link with TAK procedure

enumerator gVendorEnableExpmFeatures_c
An error occurred during gHciVendorEnableExpmFeaturesCommand_c execution

enumerator gLeSetLocalPeripheralLatencyEnable_c
An error occurred during the Le Set Local Peripheral Latency Enable procedure

enumerator gLeChasConfig_c
An error occurred during LE CHAS Config command execution

enumerator gLeModulationTest_c
An error occurred during LE Modulation Test command execution

enumerator gVendorEnableLePowerControl_c
An error occurred during gHciVendorEnableLePowerControlCommand_c execution

enum gapControllerTestEventType_t
Controller Test Event Type

Values:

enumerator gControllerReceiverTestStarted_c

enumerator gControllerTransmitterTestStarted_c

enumerator gControllerTestEnded_c

enum gapLeAllPhyFlags_t

Le All Phys Preferences flags.

Values:

enumerator gLeTxPhyNoPreference_c

Host has no preference for Tx Phy

enumerator gLeRxPhyNoPreference_c

Host has no preference for Rx Phy

enum gapLePhyOptionsFlags_t

Le Phys Options Preferences flags.

Values:

enumerator gLeCodingNoPreference_c

Host has no preference on the LE Coded Phy

enumerator gLeCodingS2_c

Host prefers to use S=2 on the LE Coded Phy

enumerator gLeCodingS8_c

Host prefers to use S=8 on the LE Coded Phy

enumerator gLeCodingS2Req_c

Host requires to use S=2 on the LE Coded Phy

enumerator gLeCodingS8Req_c

Host requires to use S=8 on the LE Coded Phy

enum gapLePhyMode_tag

Values:

enumerator gLePhy1M_c

Tx/Rx Phy on the connection is LE 1M

enumerator gLePhy2M_c

Tx/Rx Phy on the connection is LE 2M

enumerator gLePhyCoded_c

Tx/Rx Phy on the connection is LE Coded

enum gapPhyEventType_t

Phy Event Type

Values:

enumerator gPhySetDefaultComplete_c

Gap_LeSetPhy default mode was successful

enumerator gPhyRead_c
Gap_LeReadPhy return values

enumerator gPhyUpdateComplete_c
Gap_LeSetPhy return values for a connection or an update occurred

enum bleNotificationEventType_tag
Values:

enumerator gNotifEventNone_c
No enhanced notification event enabled

enumerator gNotifConnEventOver_c
Connection event over

enumerator gNotifConnRxPdu_c
Connection Rx PDU

enumerator gNotifAdvEventOver_c
Advertising event over

enumerator gNotifAdvTx_c
Advertising ADV transmitted

enumerator gNotifAdvScanReqRx_c
Advertising SCAN REQ Rx

enumerator gNotifAdvConnReqRx_c
Advertising CONN REQ Rx

enumerator gNotifScanEventOver_c
Scanning event over

enumerator gNotifScanAdvPktRx_c
Scanning ADV PKT Rx

enumerator gNotifScanRspRx_c
Scanning SCAN RSP Rx

enumerator gNotifScanReqTx_c
Scanning SCAN REQ Tx

enumerator gNotifConnCreated_c
Connection created

enumerator gNotifChannelMatrix_c
Enable channel status monitoring (KW37 only)

enumerator gNotifPhyReq_c
Phy Req Pdu ack received (KW37 only)

enumerator gNotifConnChannelMapUpdate_c
Channel map update

enumerator gNotifConnInd_c
Connect indication

enumerator gNotifPhyUpdateInd_c
Phy update indication

enum bleCteTransmitEnable_t
Values:

enumerator gCteTransmitDisable_c

enumerator gCteTransmitEnable_c

enum bleIqSamplingEnable_t
Values:

enumerator gIqSamplingDisable_c

enumerator gIqSamplingEnable_c

enum bleCteReqEnable_t
Values:

enumerator gCteReqDisable_c

enumerator gCteReqEnable_c

enum bleCteRspEnable_t
Values:

enumerator gCteRspDisable_c

enumerator gCteRspEnable_c

enum bleCteType_tag
Values:

enumerator gCteTypeAoA_c
AoA Constant Tone Extension

enumerator gCteTypeAoD1us_c
AoD Constant Tone Extension with 1 microsecond slots

enumerator gCteTypeAoD2us_c

AoD Constant Tone Extension with 2 microsecond slots

enumerator gCteTypeNoCte_c

No Constant Tone Extension

enum bleSlotDurations_tag

Values:

enumerator gSlotDurations1us_c

Switching and sampling slot durations are 1 microsecond each

enumerator gSlotDurations2us_c

Switching and sampling slot durations are 2 microseconds each

enum bleIqReportPacketStatus_tag

Values:

enumerator gIqReportPacketStatusCorrectCrc_c

CRC was correct

enumerator gIqReportPacketStatusCrcIncorrectUsedLength_c

CRC was incorrect and the Length and CTETime fields of the packet were used to determine sampling points

enumerator gIqReportPacketStatusCrcIncorrectUsedOther_c

CRC was incorrect but the Controller has determined the position and length of the Constant Tone Extension in some other way

enumerator gIqReportPacketStatusInsufficientResources_c

Insufficient resources to sample (Channel_Index, CTE_Type, and Slot_Durations invalid).

enum blePathLossThresholdZoneEntered_tag

Values:

enumerator gPathLossThresholdLowZone_c

Entered low zone.

enumerator gPathLossThresholdMiddleZone_c

Entered middle zone.

enumerator gPathLossThresholdHighZone_c

Entered high zone.

enum bleTxPowerReportingReason_tag

Values:

enumerator gLocalTxPowerChanged_c
Local transmit power changed.

enumerator gRemoteTxPowerChanged_c
Remote transmit power changed.

enumerator gReadRemoteTxPowerLevelCommandCompleted_c
HCI_LE_Read_Remote_Transmit_Power_Level command completed.

enum blePowerControlPhyType_tag
Values:

enumerator gPowerControlLePhy1M_c
LE 1M Phy.

enumerator gPowerControlLePhy2M_c
LE 2M Phy.

enumerator gPowerControlLePhyCodedS8_c
LE Coded Phy with S=8 data coding.

enumerator gPowerControlLePhyCodedS2_c
LE Coded Phy with S=2 data coding.

enum blePathLossReportingEnable_t
Values:

enumerator gPathLossReportingDisable_c

enumerator gPathLossReportingEnable_c

enum bleTxPowerReportingEnable_t
Values:

enumerator gTxPowerReportingDisable_c

enumerator gTxPowerReportingEnable_c

enum bleHandoverSuspendTransmitMode_t
Values:

enumerator gDoNotUseEventCounter_c

enumerator gUseEventCounter_c

enumerator gSafeStopLlTx_c

enumerator gSafeStopHostLlTx_c

enum bleHandoverAnchorSearchMode_t

Values:

enumerator gSuspendTxMode_c

enumerator gRssiSniffingMode_c

enumerator gPacketMode_c

enum bleGetConnParamsMode_t

Values:

enumerator gSendEventAfterRemoteSNChange_c

enumerator gSendEventAfterLLProcUpdate_c

enum bleHandoverAnchorNotificationEnable_t

Values:

enumerator gAnchorNotificationDisable_c

enumerator gAnchorNotificationEnable_c

enum bleHandoverTimeSyncEnable_t

Values:

enumerator gTimeSyncDisable_c

enumerator gTimeSyncEnable_c

enum bleHandoverTimeSyncStopWhenFound_t

Values:

enumerator gTimeSyncDoNotStopWhenFound_c

enumerator gTimeSyncStopWhenFound_c

enum bleAdvIndexType_t

Values:

enumerator gAdvIndexAscend_c

enumerator gAdvIndexDescend_c

enumerator gAdvIndexUser_c

enumerator gAdvIndexRandom_c

typedef enum *bleResult_tag* bleResult_t
BLE result type - the return value of BLE API functions

typedef uint8_t deviceId_t
Unique identifier type for a connected device.

typedef uint8_t bearerId_t
ATT bearer identifier.

typedef enum *bearerStatus_tag* bearerStatus_t
Enhanced ATT bearer status values

typedef uint8_t bleAddressType_t
Bluetooth Device Address Type - Size: 1 Octet, Range: [gBleAddrTypePublic_c:gBleAddrTypeRandom_c]

typedef uint8_t bleDeviceAddress_t[(6U)]
Bluetooth Device Address - array of 6 bytes.

typedef uint8_t bleUuidType_t
Bluetooth UUID type - values chosen to correspond with the ATT UUID format

typedef uint16_t bleAdvReportEventProperties_t
Advertising Event properties

typedef uint16_t bleAdvRequestProperties_t
Advertising Request properties

typedef uint8_t bleCentralClockAccuracy_t

typedef uint8_t bleAdvertiserClockAccuracy_t

typedef uint8_t bleScanningFilterPolicy_t
Scanning filter policy enumeration - Size: 1 Octet, Range: [gScanAll_c:gScanWithFilterAcceptList_c]

typedef uint8_t bleInitiatorFilterPolicy_t
Initiator filter policy enumeration - Size: 1 Octet, Range: [gUseDeviceAddress_c:gUseFilterAcceptList_c]

typedef uint8_t blePrivacyMode_t
Privacy Mode enumeration - Size: 1 Octet, Range: [gNetworkPrivacy_c:gDevicePrivacy_c]

typedef uint8_t bleChannelMap_t[(5U)]
Bluetooth Channel map - array of 5 bytes.

typedef uint64_t leSupportedFeatures_t

typedef uint8_t gapLePhyFlags_t
Le Tx/Rx Phys Preferences flags.

typedef uint8_t gapLePhyMode_t
Le Tx/Rx Phys.

typedef uint16_t bleNotificationEventType_t
Controller Enhanced Notification Event Type

const uint8_t gBleEattMaxConnectionChannels

const uint16_t gBleEattPsmMtu

const uint8_t gMaxAdvReportQueueSize

const bool_t gUseHciCommandFlowControl
Enables/Disables Hci Command Flow Control if the host lib supports this feature

bool_t gHostInitEnableExpmFeatures

bool_t gHostInitEnableLePowerControl

bool_t gEnableCoredumpPackets

messaging_t gApp2Host_TaskQueue
App to Host message queue for the Host Task

messaging_t gHci2Host_TaskQueue
HCI to Host message queue for the Host Task

bleResult_t Ble_HostInitialize(*gapGenericCallback_t* genericCallback,
hciHostToControllerInterface_t hostToControllerInterface)
Performs initialization of the BLE Host stack.

Remark

Application must wait for the gInitializationComplete_c generic event.

Parameters

- genericCallback – **[in]** Callback used to propagate GAP generic events to the application.
- hostToControllerInterface – **[in]** LE Controller uplink interface function pointer

Returns
gBleSuccess_c or error.

bleResult_t Ble_HostDeInitialize(void)
performs De-Initialize the Bluetooth LE Host

Remark

Application must wait for the gDeInitializationComplete_c generic event.

Parameters

- none –

Return values
gBleSuccess_c – or error.

bleResult_t Ble_HciRecv(*hciPacketType_t* packetType, void *pHciPacket, uint16_t packetSize)
This is the BLE Host downlink interface function.

Remark

This function must be registered as a callback by the LE Controller and called to send HCI packets (events and LE-U data) to the BLE Host.

Parameters

- packetType – **[in]** The type of the packet sent by the LE Controller
- pHciPacket – **[in]** Pointer to the packet sent by the LE Controller
- packetSize – **[in]** Number of bytes sent by the LE Controller

Returns
gBleSuccess_c or gBleOutOfMemory_c

bleResult_t Ble_HciRecvFromIsr(*hciPacketType_t* packetType, void *pHciPacket, uint16_t packetSize)
This is the BLE Host downlink interface function to be used in ISR context.

Remark

This function must be registered as a callback by the HCI Transport layer and called to send HCI packets from the controller (events and LE-U data) to the BLE Host.

Parameters

- packetType – **[in]** The type of the packet sent by the LE Controller
- pHciPacket – **[in]** Pointer to the packet sent by the LE Controller
- packetSize – **[in]** Number of bytes sent by the LE Controller

Returns
gBleSuccess_c or gBleOutOfMemory_c

bool_t Ble_CheckMemoryStorage(void)

This function performs runtime checks to determine whether memory storage is properly configured for the application settings.

Returns
True if memory is configured correctly False otherwise.

OSA_EVENT_HANDLE_DEFINE (gHost_TaskEvent)

Event for the Host Task Queue

void Host_TaskHandler(void *args)

Contains the Host Task logic.

Remark

This function must be called exclusively by the Host Task code from the application.

---

static inline uint16_t IncrementU16Saturating(uint16_t val, uint16_t increment)

Adds an increment to a 16-bit unsigned value, saturating at UINT16_MAX to avoid unsigned integer wraparound.

Parameters

- val – **[in]** The base value to increment.
- increment – **[in]** The value to add.

Returns
uint16_t The saturated result of val + increment.

static inline uint8_t IncrementU8Saturating(uint8_t val, uint8_t increment)

Adds an increment to an 8-bit unsigned value, saturating at UINT8_MAX to avoid unsigned integer wraparound.

Parameters

- val – **[in]** The base value to increment.
- increment – **[in]** The value to add.

Returns
uint8_t The saturated result of val + increment.

gInvalidDeviceId_c

gInvalidNvmIndex_c

gcConnectionIntervalMin_c

Boundary values for the Connection Parameters (Standard GAP).

gcConnectionIntervalMax_c

gcConnectionPeripheralLatencyMax_c

gcConnectionSupervisionTimeoutMin_c

gcConnectionSupervisionTimeoutMax_c

gcConnectionSubrateFactorMin_c

gcConnectionSubrateFactorMax_c

gcConnectionSubrateContinuationNumberMax_c

gcConnectionIntervalMinDefault_c

Default values for the Connection Parameters (Preferred).

connIntervalmin = Conn_Interval_Min * 1.25 ms

Value of 0xFFFF indicates no specific minimum.

gcConnectionIntervalMaxDefault_c

connIntervalmax = Conn_Interval_Max * 1.25 ms

Value of 0xFFFF indicates no specific maximum.

gcConnectionPeripheralLatencyDefault_c

gcConnectionSupervisionTimeoutDefault_c

Time = N * 10 ms

STATIC

When unit testing is performed, access from unit test module to static functions/variables within the tested module is not possible and therefore the static storage class identifier shall be removed

gBleAddrTypePublic_c

Bluetooth Device Address Types Public Device Address - fixed into the Controller by the manufacturer.

gBleAddrTypeRandom_c

Random Device Address - set by the Host into the Controller for privacy reasons.

Ble_IsPrivateResolvableDeviceAddress(bleAddress)

PRA condition: check the 6th byte - MSB should be 0; 2nd MSB should be 1.

Ble_IsPrivateNonresolvableDeviceAddress(bleAddress)

PNRA condition: check the 6th byte - MSB should be 0; 2nd MSB should be 0.

Ble_IsRandomStaticDeviceAddress(bleAddress)

RSA condition: check the 6th byte - MSB should be 1; 2nd MSB should be 1.

Ble_DeviceAddressesMatch(bleAddress1, bleAddress2)

A macro used to compare two device addresses

Ble_CopyDeviceAddress(destinationAddress, sourceAddress)

A macro used to copy device addresses

gBleUuidType16_c

16-bit standard UUID

gBleUuidType128_c

128-bit long/custom UUID

gBleUuidType32_c

32-bit UUID - not available as ATT UUID format

gLePhy1MFlag_c

Host prefers to use LE 1M Tx/Rx Phy, possibly among others

gLePhy2MFlag_c

Host prefers to use LE 2M Tx/Rx Phy, possibly among others

gLePhyCodedFlag_c

Host prefers to use LE Coded Tx/Rx Phy, possibly among others

gAdvDataChange_c

Advertising Data Change reason

gScanRspDataChange_c

Scan Response Data Change reason

gUseDeviceAddress_c

Initiator filter policy values Initiates a connection with a specific device identified by its address.

gUseFilterAcceptList_c

Initiates connections with all the devices in the Filter Accept List at the same time.

gUseDeviceAddressNoDecisionPDUs_c

Initiator filter policy values extended for gBLE60_DecisionBasedAdvertisingFilteringSupport_d == TRUE Filter Accept List is not used to determine which advertiser to connect to. Decision PDUs shall be ignored. Peer_Address_Type and Peer_Address shall be used.

gUseFilterAcceptListNoDecisionPDUs_c

Filter Accept List is used to determine which advertiser to connect to. Decision PDUs shall be ignored. Peer_Address_Type and Peer_Address shall be ignored.

gUseOnlyDecisionPDUs_c

Filter Accept List is not used to determine which advertiser to connect to. Only Decision PDUs shall be processed. Peer_Address_Type and Peer_Address shall be ignored.

gUseFilterAcceptListAllPDUs_c

Filter Accept List is used to determine which advertiser to connect to. All PDUs shall be processed. Peer_Address_Type and Peer_Address shall be ignored.

gUseDecisionPDU_UseFilterAcceptListForOtherPDUs_c

All decision PDUs shall be processed. Filter Accept List is used to determine which other PDUs to process. Peer_Address_Type and Peer_Address shall be ignored.

gScanAll_c

Basic Scanning filter policy values. Kept for apps backward compatibility Basic unfiltered scanning filter policy.

gScanWithFilterAcceptList_c

Basic filtered scanning filter policy (using the Filter Accept List).

gBasicUnfilteredScan_c

Scanning filter policy values. Basic unfiltered scanning filter policy.

gBasicFilteredScan_c

Basic filtered scanning filter policy (using the Filter Accept List).

gExtendedUnfilteredScan_c

Extended unfiltered scanning filter policy.

gExtendedFilteredScan_c

Extended filtered scanning filter policy(using the Filter Accept List).

gScanOnlyNonDecisionPDUs_c

PDU Scanning filter policy values. To be used in bitwise OR operations with scanning filter policy above only with gBLE60_DecisionBasedAdvertisingFilteringSupport_d == TRUE e.g. ((uint8_t)(gExtendedUnfilteredScan_c | gScanAllPDUs_c)) Scan Only Non Decision Advertising PDU.

gScanAllPDUs_c

Scan Decision and Non Decision Advertising PDU.

gScanOnlyDecisionPDUs_c

Scan Only Decision Advertising PDU.

gNetworkPrivacy_c

Privacy mode values Use Network Privacy Mode for the peer device (default)

gDevicePrivacy_c

Use Device Privacy Mode for the peer device

gUnenhancedBearerId_c

bearer id 0 is used for the Unenhanced ATT bearer

gDHKeySize_c

LE Secure Connections 256 bit DHKey

gSkdSize_c
: LL Session Key Diversfier size

gHCICSChannelMapSize
: CS Channel Map size

gCSReflectorTableSize_c
: CS reflector table size size

gCSNumPhysMax_c
: CS reflector table size size

gCSNumToneAntennaIds_c
: CS number of antenna IDs used in the pattern

gCSTestMaxChannelLength_c
: CS number of channels used in the the pattern

gDRBGKeySize_c
: CS debugger key size

gCSSyncRandomSize_c
: CS Sync Random size

gCSMaxSubeventLen_c
: CS maximum duration for each CS sub-event in microseconds

gCsAccessAdressSize_c
: CS Access Address used in SYNC packets

LL_PHY_1M

LL_PHY_2M

LL_PHY_S8

LL_PHY_S2

gVendorHandoverMaxCsLlContextSize_c
: Maximum size of the LL Context for Handover (CS context is largest)

gVendorUnitaryTestSize_c
: Maximum size of the VENDOR_UNITARY_TEST response

gVendorDebugEventSize_c
: Maximum size of the debug payload

gLeExtendedFeaturesSize_c

Current size of the leExtendedFeatures, can be raised up to 240

getLeExtendedFeatureByte(bitNumber)

getLeExtendedFeatureBit(bitNumber)

isSupportedLeExtendedFeature(features, bitNumber)

gLeModulationTestOptionPhy2M_c

LE Modulation Test Options bit definitions bit 0: 0=1M PHY, 1=2M PHY

gLeModulationTestOptionGenericChannel_c

bit 1: 0=BLE RF index, 1=generic channel

gLeModulationTestOptionPowerIndex_c

bit 2: 0=tx power in dBm, 1=power index

gBleSig_PrimaryService_d

Bluetooth SIG UUID constants for GATT declarations

Primary Service declaration UUID

gBleSig_SecondaryService_d

Secondary Service declaration UUID

gBleSig_Include_d

Include declaration UUID

gBleSig_Characteristic_d

Characteristic declaration UUID

gBleSig_CharExtendedProperties_d

Characteristic Extended Properties UUID

gBleSig_CharUserDescription_d

Client Characteristic User Description UUID

gBleSig_CCCD_d

Client Characteristic Configuration Descriptor declaration UUID

gBleSig_SCCD_d

Server Characteristic Configuration Descriptor declaration UUID

gBleSig_CharPresFormatDescriptor_d

Characteristic Presentation Format declaration UUID

gBleSig_CharAggregateFormat_d

Characteristic Aggregate Format UUID

gBleSig_ValidRangeDescriptor_d
: Valid Range Descriptor declaration UUID

gBleSig_GenericAccessProfile_d
: GAP Service UUID

gBleSig_GenericAttributeProfile_d
: GATT Service UUID

gBleSig_ImmediateAlertService_d
: Immediate Alert Service UUID

gBleSig_LinkLossService_d
: Link Loss Service UUID

gBleSig_TxPowerService_d
: Tx Power Service UUID

gBleSig_CurrentTimeService_d
: Current Time Service UUID

gBleSig_ReferenceTimeUpdateService_d
: Reference Time Update Service UUID

gBleSig_NextDSTChangeService_d
: Next DST Change Service UUID

gBleSig_GlucoseService_d
: Glucose Service UUID

gBleSig_HealthThermometerService_d
: Health Thermometer Service UUID

gBleSig_DeviceInformationService_d
: Device Information Service UUID

gBleSig_HeartRateService_d
: Heart Rate Service UUID

gBleSig_PhoneAlertStatusService_d
: Phone Alert Status Service UUID

gBleSig_BatteryService_d
: Battery Service UUID

gBleSig_BloodPressureService_d
: Blood Pressure Service UUID

gBleSig_AlertNotificationService_d
: Alert Notification Service UUID

gBleSig_HidService_d
: HID Service UUID

gBleSig_RunningSpeedAndCadenceService_d
: Running Speed And Cadence Service UUID

gBleSig_CyclingSpeedAndCadenceService_d
: Cycling Speed And Cadence Service UUID

gBleSig_CyclingPowerService_d
: Cycling Power Service UUID

gBleSig_LocationAndNavigationService_d
: Location And Navigation Service UUID

gBleSig_IpsService_d
: Internet Protocol Support Service UUID

gBleSig_PulseOximeterService_d
: Pulse Oximeter Service UUID

gBleSig_HTTPProxyService_d
: HTTP Proxy Service UUID

gBleSig_WPTService_d
: Wireless Power Transfer Service UUID

gBleSig_BtpService_d
: BTP Service UUID

gBleSig_GapDeviceName_d
: GAP Device Name Characteristic UUID

gBleSig_GapAppearance_d
: GAP Appearance Characteristic UUID

gBleSig_GapPpcp_d
: GAP Peripheral Preferred Connection Parameters Characteristic UUID

gBleSig_GattServiceChanged_d
: GATT Service Changed Characteristic UUID

gBleSig_GattClientSupportedFeatures_d
: GATT Client Supported Features Characteristic UUID

gBleSig_GattServerSupportedFeatures_d
: GATT Server Supported Features Characteristic UUID

gBleSig_GattDatabaseHash_d
: GATT Database Hash Characteristic UUID

gBleSig_AlertLevel_d
: Alert Level Characteristic UUID

gBleSig_TxPower_d
: TX Power Characteristic UUID

gBleSig_LocalTimeInformation_d
: Local Time Information Characteristic UUID

gBleSig_TimeWithDST_d
: Time With DST Characteristic UUID

gBleSig_ReferenceTimeInformation_d
: Reference Time Information Characteristic UUID

gBleSig_TimeUpdateControlPoint_d
: Time Update Control Point Characteristic UUID

gBleSig_TimeUpdateState_d
: Time Update State Characteristic UUID

gBleSig_GlucoseMeasurement_d
: Glucose Measurement Characteristic UUID

gBleSig_BatteryLevel_d
: Battery Level Characteristic UUID

gBleSig_TemperatureMeasurement_d
: Temperature Measurement Characteristic UUID

gBleSig_TemperatureType_d
: Temperature Type Characteristic UUID

gBleSig_IntermediateTemperature_d
: Intermediate Temperature Characteristic UUID

gBleSig_MeasurementInterval_d
: Measurement Interval Characteristic UUID

gBleSig_SystemId_d
: System ID Characteristic UUID

gBleSig_ModelNumberString_d
: Model Number String Characteristic UUID

gBleSig_SerialNumberString_d
: Serial Number String Characteristic UUID

gBleSig_FirmwareRevisionString_d
: Firmware Revision String Characteristic UUID

gBleSig_HardwareRevisionString_d
: Hardware Revision String Characteristic UUID

gBleSig_SoftwareRevisionString_d
: Software Revision String Characteristic UUID

gBleSig_ManufacturerNameString_d
: Manufacturer Name String Characteristic UUID

gBleSig_IeeeRcdl_d
: IEEE 11073-20601 Regulatory Certification Data List Characteristic UUID

gBleSig_CurrentTime_d
: Current Time Characteristic UUID

gBleSig_BootKeyboardInputReport_d
: Boot Keyboard Input Report UUID

gBleSig_BootKeyboardOutputReport_d
: Boot Keyboard output Report UUID

gBleSig_BootMouseInputReport_d
: Boot Mouse Input Report UUID

gBleSig_GlucoseMeasurementContext_d
: Glucose Measurement Context Characteristic UUID

gBleSig_BpMeasurement_d
: Blood Pressure Measurement UUID

gBleSig_BpEnhancedMeasurement_d
: Blood Pressure Enhanced Measurement UUID

gBleSig_BpRecord_d
: Blood Pressure Record UUID

gBleSig_IntermediateCuffPressure_d
: Intermediate Cuff Pressure UUID

gBleSig_HrMeasurement_d
: Heart Rate Measurement UUID

gBleSig_BodySensorLocation_d
: Body Sensor Location UUID

gBleSig_HrControlPoint_d
: Heart Rate Control Point UUID

gBleSig_AlertStatus_d
: Alert Status UUID

gBleSig_RingerControlPoint_d
: Ringer Control Point UUID

gBleSig_RingerSetting_d
: Ringer Setting UUID

gBleSig_AlertNotifControlPoint_d
: Alert Notif Control Point UUID

gBleSig_UnreadAlertStatus_d
: Unread Alert Status UUID

gBleSig_NewAlert_d
: New Alert UUID

gBleSig_SupportedNewAlertCategory_d
: Supported New Alert Category UUID

gBleSig_SupportedUnreadAlertCategory_d
: Supported Unread Alert Category UUID

gBleSig_BloodPressureFeature_d
: Blood Pressure Feature UUID

gBleSig_HidInformation_d
: HID Information UUID

gBleSig_HidBootMouseInputReport_d
: HID Boot Mouse Input Report UUID

gBleSig_HidCtrlPoint_d
: HID Control Point UUID

gBleSig_Report_d
: Report UUID

gBleSig_ProtocolMode_d
: Protocol Mode UUID

gBleSig_ScanIntervalWindow_d
: Scan Interval Window UUID

gBleSig_PnpId_d
: PnP Id UUID

gBleSig_GlucoseFeature_d
: Glucose Feature Characteristic UUID

gBleSig_RaCtrlPoint_d
: Record Access Ctrl Point Characteristic UUID

gBleSig_RscMeasurement_d
: RSC Measurement UUID

gBleSig_RscFeature_d
: RSC Feature UUID

gBleSig_ScControlPoint_d
: SC Control Point UUID

gBleSig_CscMeasurement_d
: CSC Measurement Characteristic UUID

gBleSig_CscFeature_d
: CSC Feature Characteristic UUID

gBleSig_SensorLocation_d
: Sensor Location Characteristic UUID

gBleSig_PlxSCMeasurement_d
: PLX Spot-Check Measurement Characteristic UUID

gBleSig_PlxContMeasurement_d
: PLX Continuous Measurement Characteristic UUID

gBleSig_PulseOximeterFeature_d
: PLX Feature Characteristic UUID

gBleSig_CpMeasurement_d
: CP Measurement Characteristic UUID

gBleSig_CpVector_d
: CP Measurement Vector UUID

gBleSig_CpFeature_d
: CP Feature CharacteristicUUID

gBleSig_CpControlPoint_d
: CP Control Point UUID

gBleSig_LocationAndSpeed_d
: Location and Speed Characteristic UUID

gBleSig_Navigation_d
: Navigation Characteristic UUID

gBleSig_PositionQuality_d
: Position Quality Characteristic UUID

gBleSig_LnFeature_d
: LN Feature Characteristic UUID

gBleSig_LnControlPoint_d
: LN Control Point Characteristic UUID

gBleSig_Temperature_d
: Temperature Characteristic UUID

gBleSig_CentralAddressResolution_d
: Central Address Resolution Characteristic UUID

gBleSig_URI_d
: URI Characteristic UUID

gBleSig_HTTP_Headers_d
: HTTP Headers Characteristic UUID

gBleSig_HTTP_StatusCode_d
: HTTP Status Code Characteristic UUID

gBleSig_HTTP_EntityBody_d
: HTTP Entity Body Characteristic UUID

gBleSig_HTTP_ControlPoint_d
: HTTP Control Point Characteristic UUID

gBleSig_HTTPS_Security_d
: HTTPS Security Characteristic UUID

gBleSig_ResolvablePrivateAddressOnly_d
: Resolvable Private Address Only Characteristic UUID

gBleSig_MeshProvisioningService_d
: BLE Mesh Provisioning Service UUID

gBleSig_MeshProxyService_d
: BLE Mesh Proxy Service UUID

gBleSig_MeshProvDataIn_d
: BLE Mesh Prov Data In Char UUID

gBleSig_MeshProvDataOut_d
: BLE Mesh Prov Data Out Char UUID

gBleSig_MeshProxyDataIn_d
: BLE Mesh Proxy Data In Char UUID

gBleSig_MeshProxyDataOut_d
: BLE Mesh Proxy Data Out Char UUID

gBleSig_GattSecurityLevels_d
: LE GATT Security Levels characteristic UUID

gBleSig_EncryptedDataKeyMaterial_d
: Encrypted Data Key Material characteristic UUID

gBleSig_CAR_NotSupported_d
: Central Address Resolution Characteristic Values

gBleSig_CAR_Supported_d

gBleSig_RPAO_Used_d
: Resolvable Private Address Only Characteristic Values

gBleSig_RangingService_d
: Ranging Service UUID

gBleSig_RasFeature_d
: RAS Feature Characteristic UUID

gBleSig_RasRealTimeProcData_d
: RAS Real-time Procedure Data Characteristic UUID

gBleSig_RasOnDemandProcData_d
: RAS On-demand Procedure Data Characteristic UUID

gBleSig_RasControlPoint_d
: RAS Control Point Characteristic UUID

gBleSig_RasProcDataReady_d
: RAS Procedure Data Ready Characteristic UUID

gBleSig_RasprocDataOverwritten_d
: RAS Procedure Data Overwritten Characteristic UUID

gBleSig_TirePressureMonitoringService_d
: Tire Pressure Monitoring System Service UUID

gBleSig_TirePressure_d
: Tire Pressure Characteristic UUID

gBleSig_TireTemperature_d
: Tire Temperature Characteristic UUID

gBleSig_TireAcceleration_d
: Tire Acceleration Characteristic UUID

gBleSig_TpmsProperties_d
: TPMS Properties Characteristic UUID

gBleSig_TpmsMonitoringModeDutyCycle_d
: TPMS Monitoring Mode Duty Cycle Characteristic UUID

gBleSig_TpmsPosition_d
: TPMS Position Characteristic UUID

gBleSig_TpmsSigningKey_d
: TPMS Signing Key UUID

BleSig_IsGroupingAttributeUuid16(uuid16)
: Macro that returns whether or not an input 16-bit UUID is a grouping type.

BleSig_IsServiceDeclarationUuid16(uuid16)
: Macro that returns whether or not an input 16-bit UUID is a Service declaration.

Uuid16(uuid)
: Macro that declares a 16 bit UUID in a *bleUuid_t* union.

Uuid32(uuid)
: Macro that declares a 32 bit UUID in a *bleUuid_t* union.

UuidArray(value)

PACKED_STRUCT
: Type qualifier - does not affect local variables of integral type

___noreturn
: Type qualifier - does not affect local variables of integral type

  Type qualifier - does not affect local variables of integral type

  Storage class modifier - alignment of a variable. It does not affect the type of the function

  Marks a function that never returns.

Utils_ExtractTwoByteValue(buf)
: Returns a uint16_t from a buffer, little-endian

Utils_ExtractThreeByteValue(buf)
: Returns a 3-byte value from a buffer, little-endian

Utils_ExtractFourByteValue(buf)
: Returns a uint32_t from a buffer, little-endian

Utils_ExtractEightByteValue(buf)
: Returns a uint64_t from a buffer, little-endian

Utils_BeExtractTwoByteValue(buf)
: Returns a uint16_t from a buffer, big-endian

Utils_BeExtractThreeByteValue(buf)
: Returns a 3-byte value from a buffer, big-endian

Utils_BeExtractFourByteValue(buf)
: Returns a uint32_t from a buffer, big-endian

Utils_PackTwoByteValue(value, buf)
: Writes a uint16_t into a buffer, little-endian

Utils_PackThreeByteValue(value, buf)
: Writes a 3-byte value into a buffer, little-endian

Utils_PackFourByteValue(value, buf)
: Writes a uint32_t into a buffer, little-endian

Utils_PackEightByteValue(value, buf)
: Writes a uint64_t into a buffer, little-endian

Utils_BePackTwoByteValue(value, buf)
: Writes a uint16_t into a buffer, big-endian

Utils_BePackThreeByteValue(value, buf)
: Writes a 3-byte value into a buffer, big-endian

Utils_BePackFourByteValue(value, buf)
: Writes a uint32_t into a buffer, big-endian

Utils_Copy8(ptr, val8)
: Writes a uint8_t into a buffer, little-endian, and increments the pointer.

Utils_Copy16(ptr, val16)
: Writes a uint16_t into a buffer, little-endian, and increments the pointer.

Utils_Copy32(ptr, val32)
: Writes a uint32_t into a buffer, little-endian, and increments the pointer.

Utils_Copy64(ptr, val64)
: Writes a uint64_t into a buffer, little-endian, and increments the pointer.

Utils_RevertByteArray(array, size)
: Reverts the order of bytes in an array - useful for changing the endianness

Uint32toUint8(x)

Uint32toUint16(x)

Uint16toUint8(x)

struct bleIdentityAddress_t
: *#include <ble_general.h>* Bluetooth Identity Address - array of 6 bytes.

Public Members

bleAddressType_t idAddressType
Public or Random (static).

bleDeviceAddress_t idAddress
6-byte address.

union bleUuid_t
#include <ble_general.h> Union for a Bluetooth UUID; selected according to an accompanying bleUuidType_t

Public Members

uint16_t uuid16
For gBleUuidType16_c.

uint32_t uuid32
For gBleUuidType32_c.

uint8_t uuid128[16]
For gBleUuidType128_c.

struct bleAdvertisingChannelMap_t
#include <ble_general.h>

Public Members

uint8_t enableChannel37
Bit for channel 37.

uint8_t enableChannel38
Bit for channel 38.

uint8_t enableChannel39
Bit for channel 39.

uint8_t reserved
Reserved for future use.

struct gapLeScOobData_t
#include <ble_general.h>

Public Members

uint8_t randomValue[(16U)]

LE SC OOB r (Random value)

uint8_t confirmValue[(16U)]

LE SC OOB Cr (Random Confirm value)

struct gapInternalError_t

#include <ble_general.h> Internal Error Event Data

Public Members

bleResult_t errorCode

Host Stack error code.

gapInternalErrorSource_t errorSource

The command that generated the error; useful when it is not obvious from the error code.

uint16_t hciCommandOpcode

Only for errorSource = gHciCommandStatus_c; the HCI Command that received an error status.

struct gapControllerTestEvent_t

#include <ble_general.h> Controller Test Event

struct gapPhyEvent_t

#include <ble_general.h> Phy Event

struct bleNotificationEvent_t

#include <ble_general.h> Controller Enhanced Notification Event

Public Members

bleNotificationEventType_t eventType

Enhanced notification event type

deviceId_t deviceId

Device id of the peer, valid for connection events

int8_t rssi

RSSI, valid for Rx event types

uint8_t channel

Channel, valid for conn event over or Rx/Tx events

uint16_t ce_counter

Connection event counter, valid for conn event over or Conn Rx event

bleResult_t status

Status of the request to select which events to be enabled/disabled

uint32_t timestamp

Timestamp in microseconds, valid for Conn Rx event and Conn Created event

uint8_t adv_handle

Advertising Handle, valid for advertising events, if multiple ADV sets supported

bleDeviceAddress_t scanned_addr

Scanned address, valid for gNotifScanAdvPktRx_c event, all-zeroes otherwise

struct gapInitComplete_t

#include <ble_general.h> gInitializationComplete_c event data

struct bleBondCreatedEvent_tag

#include <ble_general.h> Bond Created Event

Public Members

uint8_t nvmIndex

NVM index for the new created bond

bleAddressType_t addressType

Public or Random (static) address of the bond

bleDeviceAddress_t address

Address of the bond

struct gapAddrReadyEvent_t_tag

#include <ble_general.h> Address Ready Event

Public Members

bleDeviceAddress_t aAddress

Generated device address

uint8_t advHandle

Advertising set handle if the generated device address will be used on an extended set. Reserved value 0xFF for other purposes: legacy advertising or scanning and initiating address.

struct bleSupportedSwitchingSamplingRates_t

#include <ble_general.h>

Public Members

uint8_t switchingSupportedAodTransmission
Bit to mark that 1 us switching is supported for AoD transmission.

uint8_t samplingSupportedAodReception
Bit to mark that 1 us sampling is supported for AoD reception.

uint8_t switchingSamplingSupportedAoaReception
Bit to mark that 1 us switching and sampling is supported for AoA reception.

uint8_t reserved
Reserved for future use.

struct bleAntennaInformation_tag
#include <ble_general.h> Antenna Information Read Event

struct periodicAdvSyncTransferEvent_tag
#include <ble_general.h>

struct periodicAdvSetInfoTransferEvent_tag
#include <ble_general.h>

struct periodicAdvSetSyncTransferParamsEvent_tag
#include <ble_general.h>

struct gapSyncTransferReceivedEventData_tag
#include <ble_general.h>

Public Members

deviceId_t deviceId
Id of the connected device from which we received periodic advertising sync transfer

uint16_t serviceData
A value provided by the peer device

uint16_t syncHandle
Sync Handle identifying the periodic advertising train

uint8_t advSID
Value of the Advertising SID used to advertise the periodic advertising

bleAddressType_t advAddressType
Device's advertising address type.

bleDeviceAddress_t advAddress
Device's advertising address.

gapLePhyMode_t advPhy
PHY used for advertising

uint16_t periodicAdvInt
Periodic advertising interval

bleCentralClockAccuracy_t advClockAccuracy
Advertiser clock accuracy

uint8_t numSubevents
Only relevant for v2 of the event, otherwise value is 0

uint8_t subeventInterval
Only relevant for v2 of the event, otherwise value is 0

uint8_t responseSlotDelay
Only relevant for v2 of the event, otherwise value is 0

uint8_t responseSlotSpacing
Only relevant for v2 of the event, otherwise value is 0

struct getConnParams_tag
#include <ble_general.h>

Public Members

uint16_t connectionHandle
Connection identifier

uint32_t ulTxAccCode
Access address

uint8_t aCrcInitVal[3U]
CRC init

uint16_t uiConnInterval
Connection interval (unit 1.25ms)

uint16_t uiSuperTO
Supervision timeout (unit 10ms)

uint16_t uiConnLatency
Latency (unit connection interval)

uint8_t aChMapBm[5U]
Channel map (FF FF FF FF 1F if all channels are used)

uint8_t ucChannelSelection
: Hop algorithm (0/1 for hop algorithm #1 or #2)

uint8_t ucHop
: Hop increment

uint8_t ucUnMapChIdx
: Unmapped channel index (used only for hop algorithm #1)

uint8_t ucCentralSCA
: Sleep clock accuracy (0 to 7)

uint8_t ucRole
: Role (0 for central and 1 for peripheral)

uint8_t aucRemoteMasRxPHY
: TX/RX PHY

uint8_t seqNum
: Sequence number; b1 and b0: the latest received SN and NESN; b5 and b4: the latest transmitted SN and NESN; other fields are reserved.

uint16_t uiConnEvent
: Current connection event counter

uint32_t ulAnchorClk
: Slot of the anchor point timing of the connection event

uint16_t uiAnchorDelay
: Slot offset of the anchor point timing of the connection event

uint32_t ulRxInstant
: Last successful access address reception instant (unit 625us)

struct handoverGetTime_tag
: *#include <ble_general.h>*

Public Members

bleResult_t status
: Command status

uint32_t slot
: LL timing slot counter (unit 625us)

uint16_t us_offset
: LL timing slot offset (0 to 624, unit us)

struct handoverAnchorSearchStart_tag

#include <ble_general.h>

Public Members

bleResult_t status

Command status

uint16_t connectionHandle

Connection identifier

struct handoverAnchorSearchStop_tag

#include <ble_general.h>

Public Members

bleResult_t status

Command status

uint16_t connectionHandle

Connection identifier

struct handoverConnect_tag

#include <ble_general.h>

Public Members

bleResult_t status

Command status

uint16_t connectionHandle

Connection identifier

struct handoverGetData_tag

#include <ble_general.h>

Public Members

bleResult_t status

Command status

uint32_t *pData

Connection handover data

struct handoverSetData_tag

#include <ble_general.h>

Public Members

bleResult_t status
Command status

uint32_t *pData
Connection handover data

struct handoverGetCsLlContext_tag
#include <ble_general.h>

Public Members

bleResult_t status
Command status

uint16_t responseMask
LL context bitmap indicating the Channel Sounding context

uint8_t llContextLength
Context data length

uint8_t llContext[(224U)]
LL Context

struct handoverAnchorMonitorEvent_tag
#include <ble_general.h>

Public Members

uint16_t connectionHandle
Connection identifier

uint16_t connEvent
Current connection event counter

int8_t rssiRemote
RSSI of the packet from the remote device (+127 if not available)

uint8_t lqiRemote
LQI (Link Quality Indicator) of the packet from the remote device

uint8_t statusRemote
Status of the packet from the remote device; b0: NESN; b1: SN; b2: CRC status valid (1) or invalid (0); b3: RSSI status valid (1) or invalid (0)

int8_t rssiActive

RSSI of the packet from the active device (+127 if not available)

uint8_t lqiActive

LQI (Link Quality Indicator) of the packet from the active device

uint8_t statusActive

Status of the packet from the active device; b0: NESN; b1: SN; b2: CRC status valid (1) or invalid (0); b3: RSSI status valid (1) or invalid (0)

uint32_t anchorClock625Us

Slot of the anchor point timing of the connection event

uint16_t anchorDelay

Slot offset of the anchor point timing of the connection event

uint8_t chIdx

BLE channel index

uint8_t ucNbReports

Number of remaining reports including the current one; 0: continuous reporting; 1-255: remaining number of reports to receive including the current one

struct handoverAnchorMonitorPacketEvent_tag

#include <ble_general.h>

Public Members

uint8_t packetCounter

Packet counter, incremented for each event

uint16_t connectionHandle

Connection identifier

uint8_t statusPacket

Status of the packet

uint8_t phy

PHY (0/1/2/3 for 1M/2M/LR S8/LR S2)

uint8_t chIdx

BLE channel index

int8_t rssiPacket

RSSI of the packet (+127 if not available)

uint8_t lqiPacket

LQI (Link Quality Indicator) of the packet

uint16_t connEvent

Current connection event counter

uint32_t anchorClock625Us

Slot value of packet start time (in 625us unit)

uint16_t anchorDelay

Slot offset value of packet start time (in 1us unit)

uint8_t ucNbConnIntervals

Number of remaining connection intervals to monitor including the current one; 0: continuous reporting; 1-255: remaining number of reports to receive including the current one

uint8_t pduSize

PDU length

uint8_t *pPdu

Full or first part of the data PDU including: PDU header, payload if present, MIC if present, CRC

struct handoverAnchorMonitorPacketContinueEvent_tag

#include <ble_general.h>

Public Members

uint8_t packetCounter

Packet counter, incremented for each event

uint16_t connectionHandle

Connection identifier

uint8_t pduSize

PDU length

uint8_t *pPdu

Full or first part of the data PDU including: PDU header, payload if present, MIC if present, CRC

struct handoverConnectionUpdateProcedureEvent_tag

#include <ble_general.h>

Public Members

uint16_t connectionHandle

Connection identifier

uint8_t winSize

Used to indicate the transmitWindowSize value as: transmitWindowSize = winSize * 1.25 ms

uint16_t winOffset

Used to indicate the transmitWindowOffset value as: transmitWindowOffset = winOffset * 1.25 ms

uint16_t interval

Used to indicate the connInterval value, as: connInterval = interval * 1.25 ms

uint16_t latency

Used to indicate the connPeripheralLatency value as: connPeripheralLatency = latency

uint16_t timeout

Used to indicate the connSupervisionTimeout value as: connSupervisionTimeout = timeout * 10 ms

uint16_t instant

Connection event counter value indicating when the new connection parameters are applied

uint16_t currentEventCounter

Current connection event counter

struct handoverTimeSyncEvent_tag

#include <ble_general.h>

Public Members

uint32_t txClkSlot

Transmitter packet start time in slot (625 us)

uint16_t txUs

Transmitter packet start time offset inside the slot (0 to 624 us)

uint32_t rxClkSlot

Receiver packet start time in slot (625 us)

uint16_t rxUs

Receiver packet start time offset inside the slot (0 to 624 us)

uint8_t rssi

RSSI

struct handoverConnParamUpdateEvent_tag

#include <ble_general.h>

Public Members

uint8_t status

Status indicating the event trigger source: bit 0: remote SN^NESN toggled; bit 1: local SN^NESN toggled; bit 2: RFU; bit 3: phy update procedure; bit 4: channel map update procedure

uint16_t connectionHandle

Connection identifier

uint32_t ulTxAccCode

Access address

uint8_t aCrcInitVal[3U]

CRC init

uint16_t uiConnInterval

Connection interval (unit 1.25ms)

uint16_t uiSuperTO

Supervision timeout (unit 10ms)

uint16_t uiConnLatency

Latency (unit connection interval)

uint8_t aChMapBm[5U]

Channel map (FF FF FF FF 1F if all channels are used)

uint8_t ucChannelSelection

Hop algorithm (0/1 for hop algorithm #1 or #2)

uint8_t ucHop

Hop increment

uint8_t ucUnMapChIdx

Unmapped channel index (used only for hop algorithm #1)

uint8_t ucCentralSCA

Sleep clock accuracy (0 to 7)

uint8_t ucRole

Role (0 for central and 1 for peripheral)

uint8_t aucRemoteMasRxPHY

TX/RX PHY

uint8_t seqNum

Sequence number; b1 and b0: the latest received SN and NESN; b5 and b4: the latest transmitted SN and NESN; other fields are reserved.

uint16_t uiConnEvent

Current connection event counter

uint32_t ulAnchorClk

Slot of the anchor point timing of the connection event

uint16_t uiAnchorDelay

Slot offset of the anchor point timing of the connection event

uint32_t ulRxInstant

Last successful access address reception instant (unit 625us)

struct handoverSuspendTransmitCompleteEvent_tag

#include <ble_general.h>

Public Members

uint16_t connectionHandle

Connection identifier

uint8_t noOfPendingAclPackets

Number of pending ACL packets (including the packet being transmitted partially or fully but not fully acked)

uint16_t sizeOfPendingAclPackets

Pending ACL packet data size including all the data in the oldest packet:

- data transmitted but not acked in the oldest ACL packet
- data transmitted and acked in the oldest ACL packet

uint16_t sizeOfDataTxInOldestPacket

Size of data transmitted and acked in the oldest ACL packet

uint8_t sizeOfDataNAckInOldestPacket

Size of data transmitted but not acked in the oldest ACL packet

struct handoverResumeTransmitCompleteEvent_tag

#include <ble_general.h>

Public Members

uint16_t connectionHandle

Connection identifier

struct handoverUpdateConnParams_tag

#include <ble_general.h>

Public Members

bleResult_t status
Command status

uint16_t connectionHandle
Connection identifier

struct handoverApplyConnectionUpdateProcedure_tag
#include <ble_general.h>

Public Members

uint16_t connectionHandle
Connection identifier

struct handoverAnchorNotificationStateChanged_tag
#include <ble_general.h>

Public Members

uint16_t connectionHandle
Connection identifier

struct handoverLlPendingDataIndication_tag
#include <ble_general.h>

Public Members

uint16_t dataSize
Pending HCI ACL data packet size

uint8_t *pData
Pointer to message containing the HCI ACL data packet. Should be free by the application using MSG_Free()

struct gapLEGenerateDhKeyCompleteEvent_t
#include <ble_general.h>

struct gapRemoteVersionInfoRead_tag
#include <ble_general.h>

struct gapLlSkdReport_tag
#include <ble_general.h>

Public Members

deviceId_t deviceId
Peer device identifier

uint8_t aSKD[(16U)]
LL SKD

struct vendorUnitaryTestEvent_tag
#include <ble_general.h>

struct vendorSpecificDbgEvent_tag
#include <ble_general.h>

struct gapGenericEvent_t
#include <ble_general.h> Generic Event Structure = type + data

Public Members

gapGenericEventType_t eventType
Event type.

union *gapGenericEvent_t* eventData
Event data, selected according to event type.

struct bleBondIdentityHeaderBlob_t
#include <ble_general.h>

struct bleBondDataDynamicBlob_t
#include <ble_general.h>

struct bleBondDataStaticBlob_t
#include <ble_general.h>

struct bleBondDataLegacyBlob_t
#include <ble_general.h>

struct bleBondDataDeviceInfoBlob_t
#include <ble_general.h>

struct bleBondDataDescriptorBlob_t
#include <ble_general.h>

struct bleLocalKeysBlob_t
#include <ble_general.h>

struct bleBondDataBlob_t
#include <ble_general.h>

struct bleBondDataRam_t

#include <ble_general.h>

struct bleCteAllowedTypesMap_t

#include <ble_general.h>

Public Members

uint8_t allowAoA

Bit to allow AoA CTE Response.

uint8_t allowAoD1us

Bit to allow AoD CTE Response with 1 microsecond slots.

uint8_t allowAoD2us

Bit to allow AoD CTE Response with 2 microsecond slots.

uint8_t reserved

Reserved for future use.

struct bleSyncCteType_tag

#include <ble_general.h>

Public Members

uint8_t doNotSyncWithAoA

Bit for CTE type AoA.

uint8_t doNotSyncWithAoD1us

Bit for CTE type AoD 1us.

uint8_t doNotSyncWithAoD2us

Bit for CTE type AoD 2us.

uint8_t doNotSyncWithType3

Bit for CTE type 3 (reserved).

uint8_t doNotSyncWithoutCte

Bit for no CTE type.

uint8_t reserved

Reserved for future use.

struct bleTxPowerLevelFlags_t

#include <ble_general.h>

Public Members

uint8_t minimum

Tx Power Level is at minimum level.

uint8_t maximum

Tx Power Level is at maximum level.

uint8_t reserved

Reserved for future use.

union eventData

Public Members

gapInternalError_t internalError

Data for the gInternalError_c event. The error that has occurred and the command that triggered it.

uint8_t filterAcceptListSize

Data for the gFilterAcceptListSizeRead_c event. The size of the Filter Accept List.

bleDeviceAddress_t aAddress

Data for the gPublicAddressRead_c event. Contains the requested device address.

gapAddrReadyEvent_t addrReady

Data for the gRandomAddressReady_c event. Contains the generated device address and advertising handle if applicable (0xFF otherwise).

uint8_t advHandle

Data for the gRandomAddressSet_c event. Contains the handle of the configured advertising set or 0xFF for legacy advertising.

bleResult_t setupFailError

Data for the gAdvertisingSetupFailed_c event. The error that occurred during the advertising setup.

int8_t advTxPowerLevel_dBm

Data for the gExtAdvertisingParametersSetupComplete_c and gAdvTxPowerLevelRead_c events. Value in dBm.

bool_t verified

Data for the gPrivateResolvableAddressVerified_c event. TRUE if the PRA was resolved with the given IRK.

gapLeScOobData_t localOobData

Data for the gLeScLocalOobData_c event. Contains local OOB data for LESC Pairing.

bool_t newHostPrivacyState

Data for the gHostPrivacyStateChanged_c event. TRUE if enabled, FALSE if disabled.

bool_t newControllerPrivacyState

Data for the gControllerPrivacyStateChanged_c event. TRUE if enabled, FALSE if disabled.

gapControllerTestEvent_t testEvent

Data for the gControllerTestEvent_c event. Contains test event type and received packets.

bleResult_t txPowerLevelSetStatus

Data for the gTxPowerLevelSetComplete_c event. Status of the set request.

gapPhyEvent_t phyEvent

Data for the gLePhyEvent_c event. Contains Tx and Rx Phy for a connection.

deviceId_t deviceId

Data for the gTxEntryAvailable_c event.

gapInitComplete_t initCompleteData

Data for the gInitializationComplete_c event. Contains the supported features, number of advertising sets and the size of the periodic advertiser list

bleNotificationEvent_t notifEvent

Data for the gControllerNotificationEvent_c event. Contains status and adv/scan/conn event data.

bleBondCreatedEvent_t bondCreatedEvent

Data for the gBondCreatedEvent_c event. Contains the NVM index and the address of the bond.

bleDeviceAddress_t aControllerLocalRPA

Data for the gControllerLocalRPARead_c event. Contains the requested device address.

getConnParams_t getConnParams

Data for the gGetConnParamsComplete_c event

uint16_t syncHandle

Data for the gConnectionlessIqSamplingStateChanged_c event. Contains the sync handle for the advertising train.

bleAntennaInformation_t antennaInformation

Data for the gAntennaInformationRead_c. Contains antenna information.

bleResult_t perAdvSyncTransferEnable

Data for the gPeriodicAdvRecvEnableComplete_c event

periodicAdvSyncTransferEvent_t perAdvSyncTransfer

Data for the gPeriodicAdvSyncTransferComplete_c event

periodicAdvSetInfoTransferEvent_t perAdvSetInfoTransfer

Data for the gPeriodicAdvSetInfoTransferComplete_c event

periodicAdvSetSyncTransferParamsEvent_t perAdvSetSyncTransferParams

Data for the gSetPeriodicAdvSyncTransferParamsComplete_c event

bleResult_t perAdvSetDefaultPerAdvSyncTransferParams

Data for the gSetDefaultPeriodicAdvSyncTransferParamsComplete_c event

gapSyncTransferReceivedEventData_t perAdvSyncTransferReceived

Data for the gPeriodicAdvSyncTransferReceived_c event

gapLEGenerateDhKeyCompleteEvent_t leGenerateDhKeyCompleteEvent

Data for gConnEvtLeGenerateDhKeyComplete_c: new key value

uint16_t pawrSyncHandle

Data for gPeriodicAdvSetResponseDataComplete_c and gPeriodicSyncSubeventComplete_c

uint8_t pawrAdvHandle

Data for gPeriodicAdvSetSubeventDataComplete_c

handoverGetData_t handoverGetData

Data for the gHandoverGetComplete_c event

handoverSetData_t handoverSetData

Data for the gHandoverSetComplete_c event

handoverGetCsLlContext_t handoverGetCsLlContext

Data for the gHandoverGetCsLlContextComplete_c event

handoverGetTime_t handoverGetTime

Data for the gHandoverGetTime_c event

handoverConnect_t handoverConnect

Data for the gHandoverConnect_c event

handoverAnchorSearchStart_t handoverAnchorSearchStart

Data for the gHandoverAnchorSearchStarted_c event

handoverAnchorSearchStop_t handoverAnchorSearchStop

Data for the gHandoverAnchorSearchStopped_c event

handoverAnchorMonitorEvent_t handoverAnchorMonitor

Data for the gHandoverAnchorMonitorEvent_c event

handoverTimeSyncEvent_t handoverTimeSync

Data for the gHandoverTimeSyncEvent_c event

handoverSuspendTransmitCompleteEvent_t handoverSuspendTransmitComplete

Data for the gHandoverSuspendTransmitComplete_c event

handoverResumeTransmitCompleteEvent_t handoverResumeTransmitComplete

Data for the gHandoverResumeTransmitComplete_c event

handoverAnchorNotificationStateChanged_t handoverAnchorNotificationStateChanged

Data for the gHandoverAnchorNotificationStateChanged_c event

handoverConnParamUpdateEvent_t handoverConnParamUpdate

Data for the gHandoverConnParamUpdateEvent_c event

gapRemoteVersionInfoRead_t gapRemoteVersionInfoRead

Data for the hciReadRemoteVersionInformationCompleteEvent_t event

gapLlSkdReport_t gapSkdReport

Data for the gLlSkdReportEvent_c event

handoverAnchorMonitorPacketEvent_t handoverAnchorMonitorPacket

Data for the gHandoverAnchorMonitorPacketEvent_c event. pPdu must be freed by the application

handoverAnchorMonitorPacketContinueEvent_t handoverAnchorMonitorPacketContinue

Data for the gHandoverAnchorMonitorPacketContinueEvent_c event. pPdu must be freed by the application

handoverUpdateConnParams_t handoverUpdateConnParams

Data for the gHandoverUpdateConnParamsComplete_c event

handoverLlPendingDataIndication_t handoverLlPendingDataIndication

Data for the gHandoverLlPendingData_c event

handoverConnectionUpdateProcedureEvent_t handoverConnectionUpdateProcedure

Data for the gHandoverConnectionUpdateProcedureEvent_c event

handoverApplyConnectionUpdateProcedure_t handoverApplyConnectionUpdateProcedure

Data for the gHandoverApplyConnectionUpdateProcedureComplete_c event

vendorUnitaryTestEvent_t unitaryTestData

Data for the gVendorUnitaryTestComplete_c event

uint8_t monAdvListSize

Data for the gMonAdvListSizeRead_c event. The size of the Monitored Advertisers List.

vendorSpecificDbgEvent_t vendorDebug

Data for the gVendorDebugEvent_c event.

union ___unnamed2___

Public Members

uint32_t raw[((40U) + 3U) / sizeof(uint32_t)]

uint8_t pKey[(40U)]

Bluetooth configuration

gcBleDeviceAddressSize_c
: Size of a BLE Device Address

gBleBondDataDynamicSize_c
: Size of bond data structures for a bonded device

gBleBondDataStaticSize_c

gBleBondDataLegacySize_c

gBleBondDataDeviceInfoSize_c

gBleBondDataDescriptorSize_c

gcSecureModeSavedLocalKeysNo_c

gcGapMaximumSavedCccds_c
: Maximum number of CCCDs

gcGapMaxAuthorizationHandles_c
: Maximum number of attributes that require authorization

gBleBondDataSize_c
: Bonding Data Size

gcBleLongUuidSize_c
: Size of long UUIDs

gcSmpMaxLtkSize_c
: Maximum Long Term Key size in bytes

gcSmpMaxBlobSize_c
: Maximum Long Term Key blob size in bytes

gcSmpIrkSize_c
: Identity Resolving Key size in bytes

gcSmpMaxIrkBlobSize_c
: Maximum Identity Resolving Key blob size in bytes

gcSmpCsrkSize_c

Connection Signature Resolving Key size in bytes - deprecated, not used

gcSmpMaxRandSize_c

Maximum Rand size in bytes

gcSmpOobSize_c

SMP OOB size in bytes

gSmpLeScRandomValueSize_c

SMP LE Secure Connections Pairing Random size in bytes

gSmpLeScRandomConfirmValueSize_c

SMP LE Secure Connections Pairing Confirm size in bytes

gcGapMaxDeviceNameSize_c

Maximum device name size

gcGapMaxAdvertisingDataLength_c

Maximum size of advertising and scan response data

gAttDefaultMtu_c

Default value of the ATT_MTU

gAttMaxMtu_c

Maximum possible value of the ATT_MTU for this device. This is used during the MTU Exchange.

gEattMaxMtu_c

Maximum possible value of the ATT_MTU for enhanced ATT bearers on this device.

gAttMaxValueLength_c

The maximum length of an attribute value shall be 512 octets.

gEattMinMtu_c

Minimum MTU size for enhanced ATT channels is 64.

gHciTransportUartChannel_c

Channel the number of the UART hardware module (For example, if UART1 is used, this value should be 1).

gcReservedFlashSizeForCustomInformation_c

Number of bytes reserved for storing application-specific information about a device

gcBleChannelMapSize_c

Size of a channel map in a connection

gBleMinTxOctets_c

gBleMinTxTime_c

gBleMaxTxOctets_c

gBleMaxTxTime_c

gBleMaxTxTimeCodedPhy_c

gBleCteMinTxOctets_c

gBleCteMinTxTime_c

gBleCteMaxTxOctets_c

gBleCteMaxTxTime_c

gBleExtAdvMaxSetId_c
: Maximum value of the advertising SID.

gBlePeriodicAdvMaxSyncHandle_c
: Maximum value of the periodic advertising handle.

gBleExtAdvLegacySetId_c
: SID of the legacy advertising set.

gBleExtAdvLegacySetHandle_c
: Handle of the legacy advertising set.

gBleExtAdvDefaultSetId_c
: Default SID for extended advertising.

gBleExtAdvDefaultSetHandle_c
: Default handle for extended advertising.

gBleAdvTxPowerNoPreference_c
: Host has no preference for Tx Power

gBleExtAdvNoDuration_c
: No advertising duration. Advertising to continue until the Host disables it.

gBleHighDutyDirectedAdvDuration
: Default advertising duration in high duty directed advertising 1.28s = 1280ms/10ms(unit) = 128

gBleExtAdvNoMaxEvents_c
: No maximum number of advertising events.

gBlePeriodicAdvDefaultHandle_c
: Periodic advertising default handle.

gBlePeriodicAdvSyncTimeoutMin_c
: Minimum value for the sync_timeout parameter

gBlePeriodicAdvSyncTimeoutMax_c
: Maximum value for the sync_timeout parameter

gBlePeriodicAdvSkipMax_c
: Maximum value for the skip parameter

gBleMaxADStructureLength_c
: Maximum length of an AD structure

gBleMaxExtAdvDataLength_c
: Maximum length of Extended Advertising Data

gBleExtAdvMaxAuxOffsetUsec_c
: Maximum value in us of AUX Offset(13 bits) in AuxPtr in 300us units, i.e. ((1 « 13) - 1) * 300

gBleP256KeyLength_c
: Length of P-256 key in octets

gcDecisionDataKeySize_c
: decision data key size in bytes

gcDecisionInstructionsParamSize_c
: decision instructions parameter size in bytes

gcDecisionInstructionsArbitraryDataMaskSize_c
: decision instructions arbitrary data mask size in bytes

gcDecisionInstructionsArbitraryDataTargetSize_c
: decision instructions arbitrary data target size in bytes

gcDecisionDataPrandSize_c
: decision data random part size in bytes

gcDecisionDataMaxSize_c
: decision data maximum size in bytes

gcDecisionDataResolvableTagSize_c
: decision data maximum size in bytes

gcMaxNumTestsInDecisionInstruction_c
: The maximum number of tests in the Gap_SetDecisionInstructions ((max param length) - sizeof(numTests))/((sizeof(TestFlag) + sizeof(TestField) + sizeof(TestParameters)) = (255-1)/(1 + 1 + 16)

gcEadRandomizerSize_c
: Size of the Encrypted Advertising Data randomizer in bytes

gcEadMicSize_c
: Size of the Encrypted Advertising Data MIC in bytes

gcEadIvSize_c
: Size of the Encrypted Advertising Data Initialization Vector in bytes

gcEadKeySize_c
: Size of the Encrypted Advertising Data Key in bytes

gcEadAadValue_c
: Value of the Additional Authentication Data field for the CCM algorithm used by EAD

gBleMonAdvRssiThresholdMin_c
: Minimum RSSI threshold value for Monitored Advertisers

gBleMonAdvRssiThresholdMax_c
: Maximum RSSI threshold value for Monitored Advertisers

gLeModulationTestMaxBleRfChannel_c
: LE Modulation Test - Maximum BLE RF channel number (0-39)

gLeModulationTestMaxGenericChannel_c
: LE Modulation Test - Maximum generic channel number (0-127)

gLeModulationTestMaxPowerIndex_c
: LE Modulation Test - Maximum power index (0-62)

bleResult_t L2ca_RegisterLeCbCallbacks(*l2caLeCbDataCallback_t* pCallback, *l2caLeCbControlCallback_t* pCtrlCallback)

Registers callbacks for credit based data and control events on L2CAP.

Parameters

- pCallback – **[in]** Callback function for data plane messages.
- pCtrlCallback – **[in]** Callback function for control plane messages.

Return values

- gL2caSuccess_c – Successful callbacks installation.
- gL2caCallbackAlreadyInstalled_c – Callbacks already installed.

bleResult_t L2ca_RegisterLePsm(uint16_t lePsm, uint16_t lePsmMtu)

Registers the LE_PSM from the L2CAP.

Parameters

- lePsm – **[in]** Bluetooth SIG or Vendor LE_PSM.
- lePsmMtu – **[in]** MTU of the registered PSM.

Return values

- gL2caLePsmInsufficientResources_c – No free LE_PSM registration slot was found.
- gL2caLePsmInvalid_c – Invalid LE_PSM value.
- gL2caLePsmAlreadyRegistered_c – LE_PSM already registered.
- gL2caSuccess_c – Successful LE_PSM registration.

bleResult_t L2ca_DeregisterLePsm(uint16_t lePsm)

Unregisters the LE_PSM from the L2CAP.

Parameters

- lePsm – **[in]** Bluetooth SIG or Vendor LE_PSM.

Return values

- gL2caSuccess_c – Successful LE_PSM deregistration.
- gL2caLePsmNotRegistered_c – LE_PSM value not registered.
- gL2caInternalError_c – There are connected L2CAP channels for the LE_PSM

Pre

An LE_PSM must be registered a priori.

bleResult_t L2ca_ConnectLePsm(uint16_t lePsm, *deviceId_t* deviceId, uint16_t initialCredits)

Initiates a connection with a peer device for a registered LE_PSM.

Parameters

- lePsm – **[in]** Bluetooth SIG or Vendor LE_PSM.
- deviceId – **[in]** The DeviceID for which the command is intended.
- initialCredits – **[in]** Initial credits.

Return values

- gL2caSuccess_c – Successful application to host message sent.
- gBleOutOfMemory_c – Message allocation fail.
- gBleInvalidParameter_c – Invalid Device Id.

Pre

An LE_PSM must be registered a priori.

bleResult_t L2ca_DisconnectLeCbChannel(*deviceId_t* deviceId, uint16_t channelId)

Disconnects a peer device for a registered LE_PSM.

Remark

Once this command is issued, all incoming data in transit for this device shall be discarded and any new additional outgoing data shall be discarded.

Parameters

- deviceId – **[in]** The DeviceID for which the command is intended.
- channelId – **[in]** The L2CAP Channel Id assigned on the initiator.

Return values

- gL2caSuccess_c – Successful application to host message sent.
- gBleOutOfMemory_c – Message allocation fail.
- gBleInvalidParameter_c – Invalid Device Id.

Pre

A connection must have already been created.

bleResult_t L2ca_CancelConnection(uint16_t lePsm, *deviceId_t* deviceId, *l2caLeCbConnectionRequestResult_t* refuseReason)

Terminates an L2CAP channel.

Remark

This interface can be used for a connection pending creation.

Parameters

- lePsm – **[in]** Bluetooth SIG or Vendor LE_PSM.
- deviceId – **[in]** The DeviceID for which the command is intended.
- refuseReason – **[in]** Reason to refuse the channel creation.

Return values

- gL2caSuccess_c – Successful application to host message sent.
- gBleOutOfMemory_c – Message allocation fail.
- gBleInvalidParameter_c – Invalid Device Id.

bleResult_t L2ca_SendLeCbData(*deviceId_t* deviceId, uint16_t channelId, const uint8_t *pPacket, uint16_t packetLength)

Sends a data packet through a Credit-Based Channel.

Parameters

- deviceId – **[in]** The DeviceID for which the command is intended.
- channelId – **[in]** The L2CAP Channel Id assigned on the initiator.
- pPacket – **[in]** Data buffer to be transmitted.
- packetLength – **[in]** Length of the data buffer.

Return values

- gL2caSuccess_c – Successful application to host message sent.
- gBleInvalidParameter_c – Invalid Device Id.
- gBleOverflow_c – Tx queue of the device is not empty.
- gBleOutOfMemory_c – Message or packet allocation fail.

Pre

An L2CAP Credit Based connection must be in place.

bleResult_t L2ca_SendLeCredit(*deviceId_t* deviceId, uint16_t channelId, uint16_t credits)

Sends credits to a device when capable of receiving additional LE-frames.

Parameters

- deviceId – **[in]** The DeviceID to which credits are given.
- channelId – **[in]** The L2CAP Channel Id assigned on the initiator.
- credits – **[in]** Number of credits to be given.

Return values

- gL2caSuccess_c – Successful application to host message sent.
- gBleOutOfMemory_c – Message allocation fail.
- gBleInvalidParameter_c – Invalid device id.

Pre

An L2CAP Credit Based connection must be in place.

bleResult_t L2ca_EnhancedConnectLePsm(uint16_t lePsm, *deviceId_t* deviceId, uint16_t mtu, uint16_t initialCredits, uint8_t noOfChannels, uint16_t *aCids)

Initiates a connection with a peer device for a registered LE_PSM. Enhanced mode: up to 5 channels can be opened.

Parameters

- lePsm – **[in]** Bluetooth SIG or Vendor LE_PSM.
- deviceId – **[in]** The DeviceID for which the command is intended.
- initialCredits – **[in]** Initial credits.
- noOfChannels – **[in]** Number of channels to request for opening. Max 5.
- aCids – **[in]** List of cids if an Enhanced Connection Request has been previously received. NULL if not.

Return values

- gL2caSuccess_c – Successful application to host message sent.
- gBleOutOfMemory_c – Message allocation fail.
- gBleInvalidParameter_c – Invalid device id or invalid noOfChannels.

Pre

A LE_PSM must be registered a priori.

bleResult_t L2ca_EnhancedChannelReconfigure(*deviceId_t* deviceId, uint16_t newMtu, uint16_t newMps, uint8_t noOfChannels, uint16_t *aCids)

Reconfigures up to 5 channels with new values for MTU and/or MPS.

Parameters

- deviceId – **[in]** The DeviceID for which the command is intended.
- newMtu – **[in]** New MTU value to be configured.
- newMps – **[in]** New MPS value to be configured.
- noOfChannels – **[in]** Number of channels to reconfigure. Max 5.
- *aCids – **[in]** The list of CIDs (endpoints on local device).

Return values

- gL2caSuccess_c – Successful application to host message sent.
- gBleOutOfMemory_c – Message allocation fail.

- gBleInvalidParameter_c – Invalid device id or invalid noOfChannels.

bleResult_t L2ca_EnhancedCancelConnection(uint16_t lePsm, *deviceId_t* deviceId, *l2caLeCbConnectionRequestResult_t* refuseReason, uint8_t noOfChannels, uint16_t *aCids)

Termination of pending L2CAP channels.

Remark

This interface can be used for an enhanced connection pending creation.

Parameters

- lePsm – **[in]** Bluetooth SIG or Vendor LE_PSM.
- deviceId – **[in]** The DeviceID for which the command is intended.
- refuseReason – **[in]** Reason to refuse the channel creation.
- noOfChannels – **[in]** Number of channels to disconnect. Max 5.
- *aCids – **[in]** The list of CIDs (endpoints on local device).

Return values

- gL2caSuccess_c – Successful application to host message sent.
- gBleOutOfMemory_c – Message allocation fail.
- gBleInvalidParameter_c – Invalid device id, invalid noOfChannels or invalid aCids pointer.

Bluetooth Low Energy Localization Application Note Introduction

NXP hardware platforms provide the features to deploy and operate Bluetooth Low Energy localization applications implementing the Channel Sounding functionality. This document provides an overview of the features and steps to run these applications on the supported NXP hardware platforms. It also describes the sample applications included in the SDK release package.

Audience

This document is a ready reference for firmware and system developers who create Bluetooth Low Energy localization enabled products. The document also provides a high-level description of Bluetooth Low Energy localization application scenarios that can be deployed on NXP development boards.

Parent topic:*Introduction*

Bluetooth Low Energy Localization Applications Overview

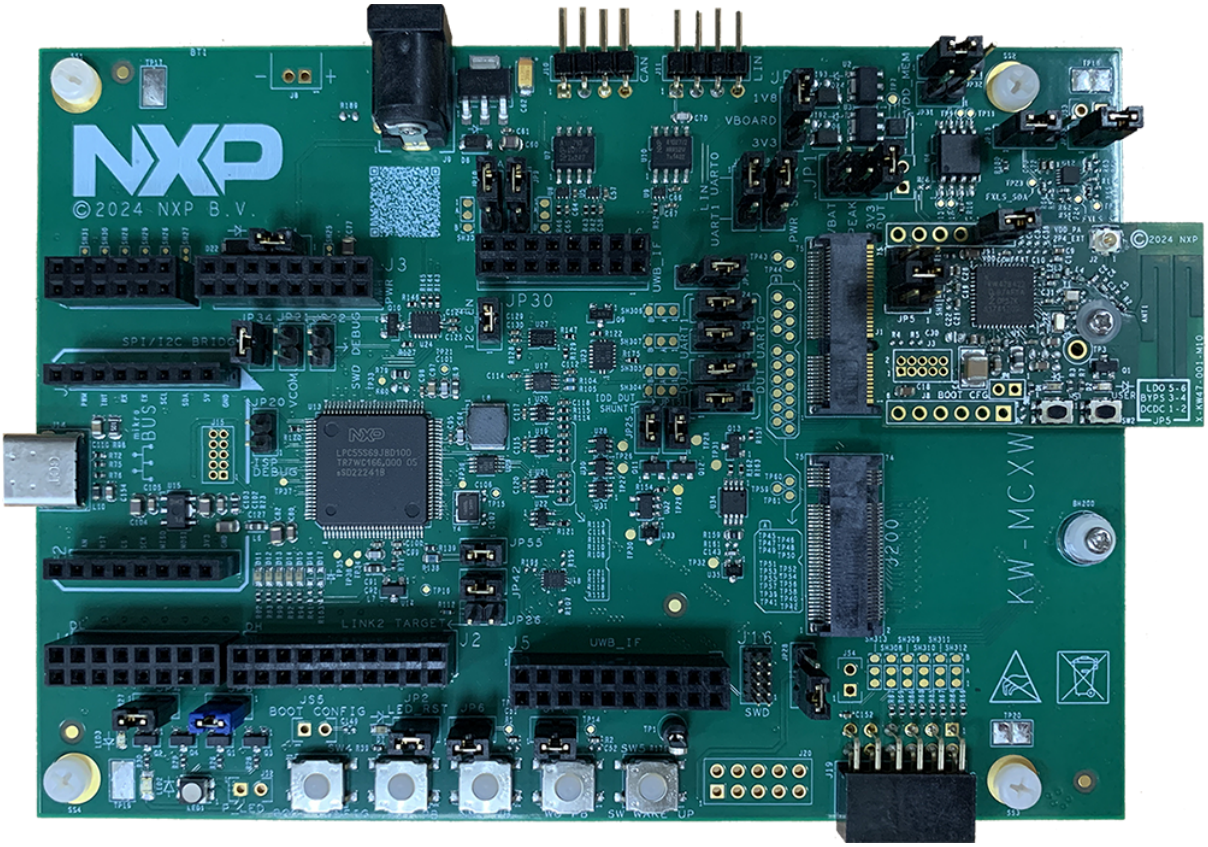
Localization Reader

The Localization Reader application implements the Ranging Service (RAS) client side. This application runs the localization algorithm using the local and remote measurement data received through RAS. Both the GAP central and peripheral roles, as well as the Channel Sounding initiator and reflector roles are supported and can be configured at compile time. In the default configuration, the application is a GAP central and Channel Sounding initiator.

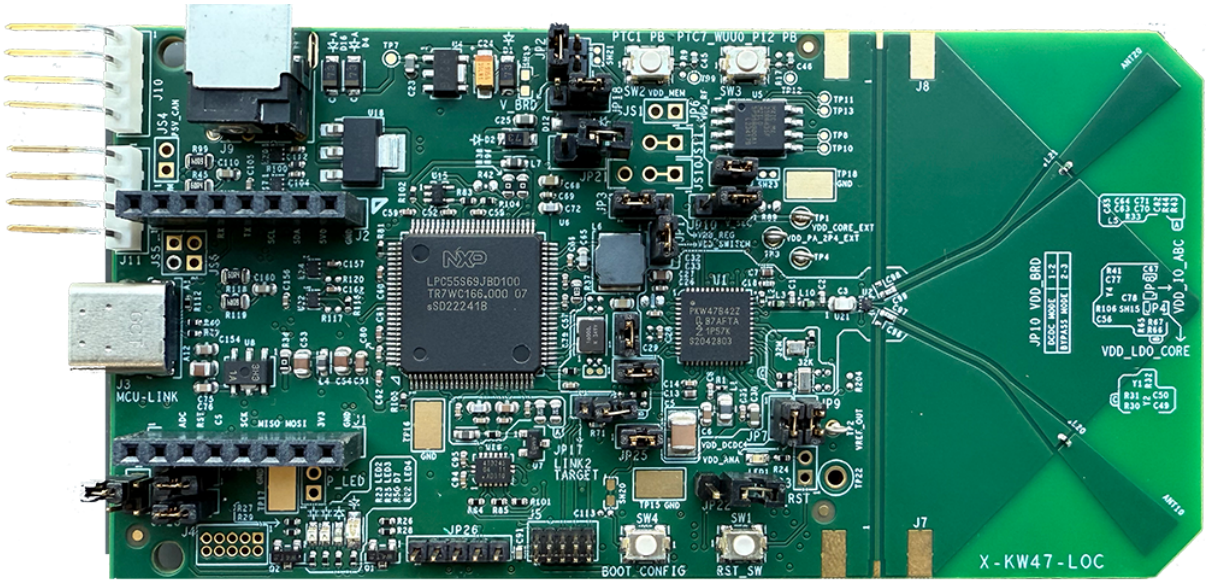
Parent topic:*Bluetooth Low Energy Localization Applications Overview*

Localization User Device

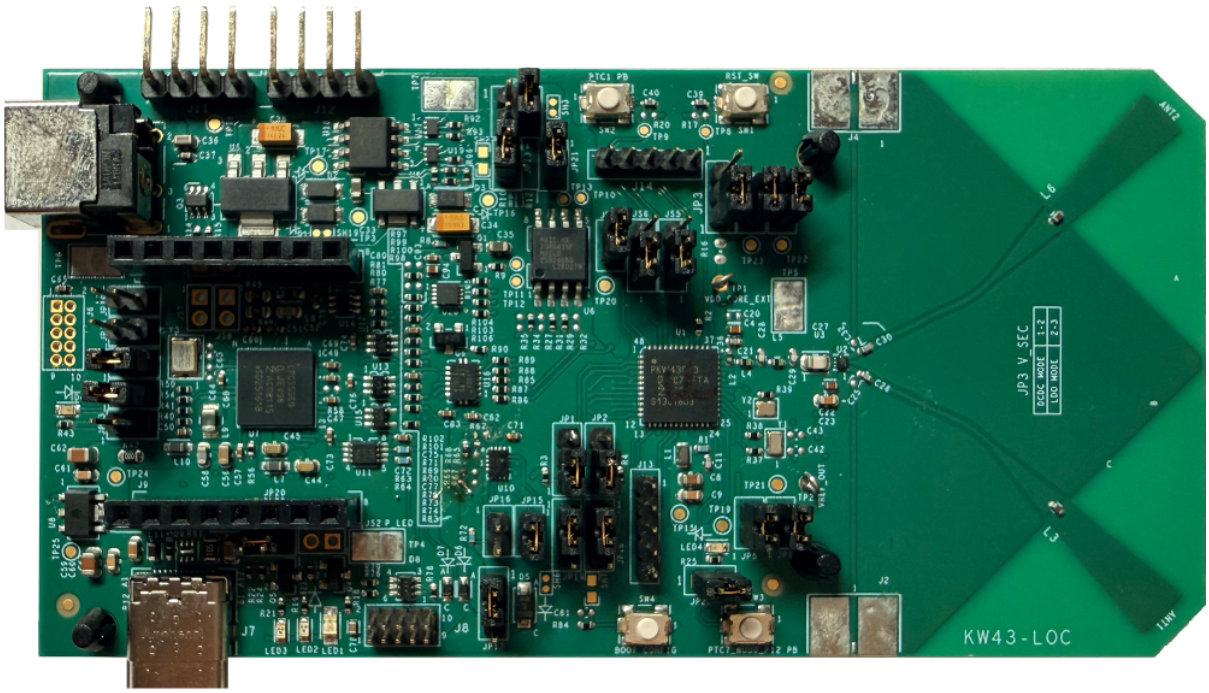
The Localization User Device implements the RAS server side. Both the GAP central and peripheral roles, as well as the Channel Sounding initiator and reflector roles are supported and can be configured at compile time. In the default configuration, the application is a GAP peripheral and Channel Sounding reflector. The Localization User Device does not run the localization algorithms.



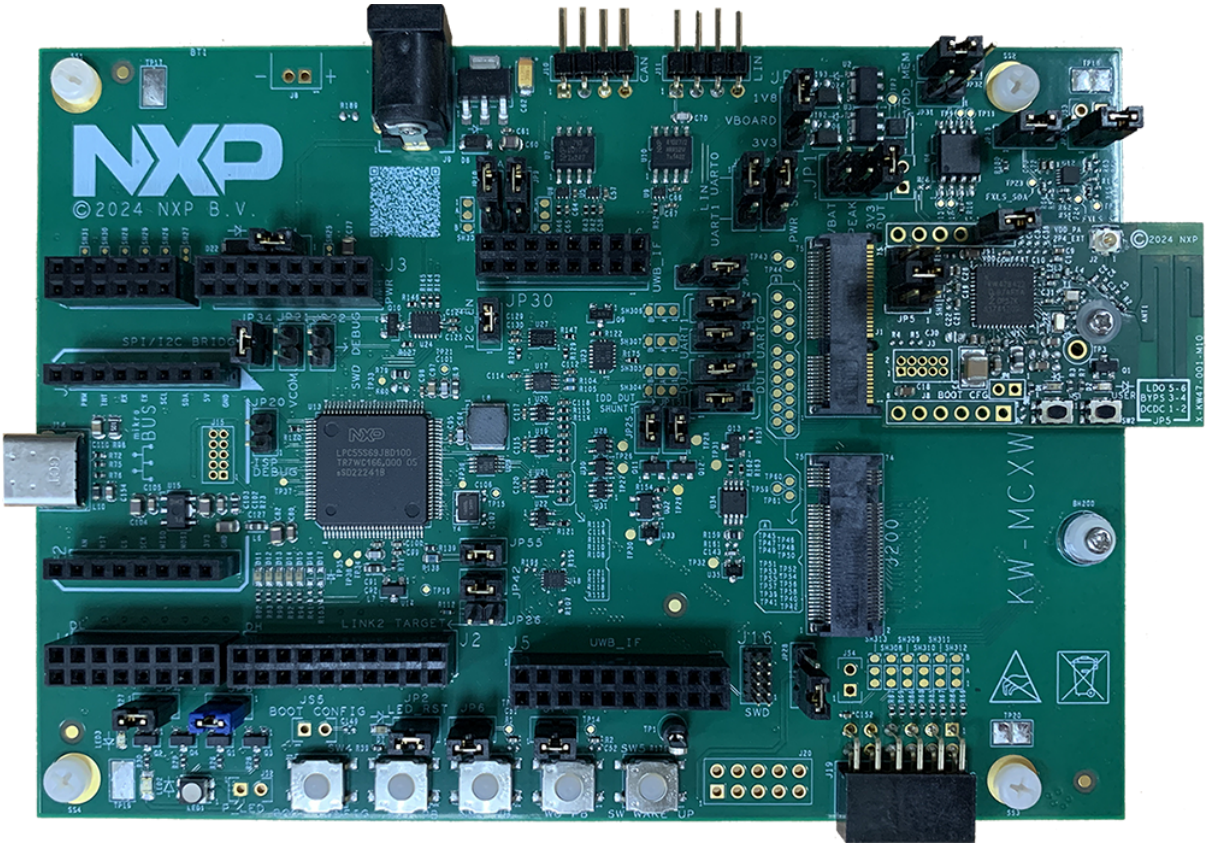
Parent topic:*Bluetooth Low Energy Localization Applications Overview*



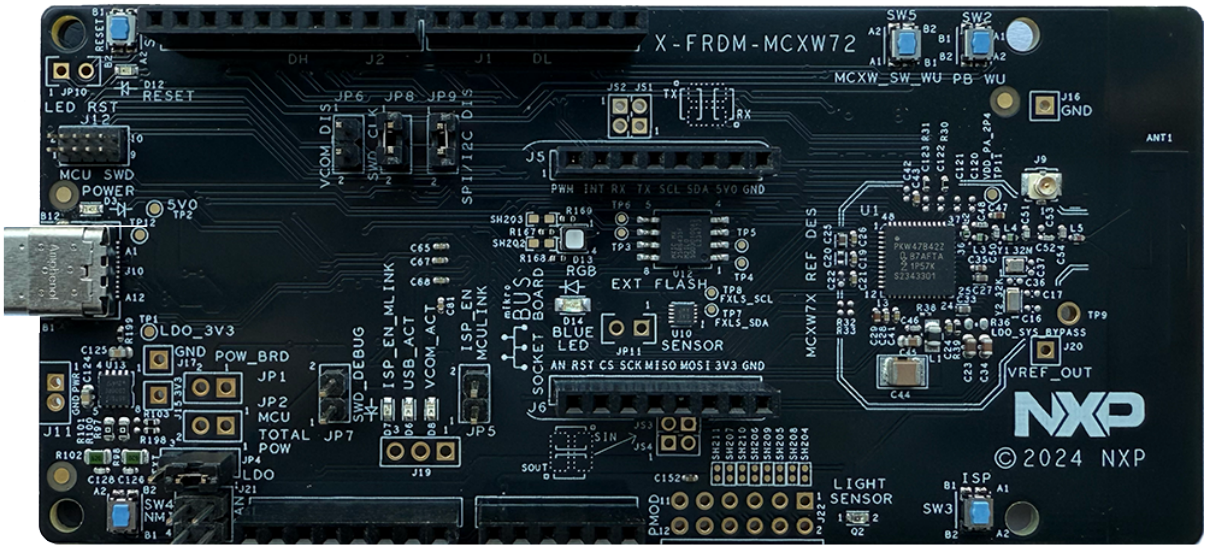
Bluetooth Low Energy Localization Hardware Platforms



The Bluetooth Low Energy Localization demo applications support the following platforms that have Bluetooth Low Energy transceiver capabilities:



- KW47-EVK (see Figure 1)
- KW47-LOC (see Figure 2)
- KW43-LOC (see Figure 3)
- MCXW72-EVK (see Figure 4)
- FRDM-MCXW72 (see Figure 5)
- MCXW72-LOC (see Figure 6)
- FRDM-KW43 (see Figure 7)



Note: The KW47/MCXW72/KW43 device family includes the LCE (Localization Compute Engine). This is a hardware accelerator for the localization algorithm.

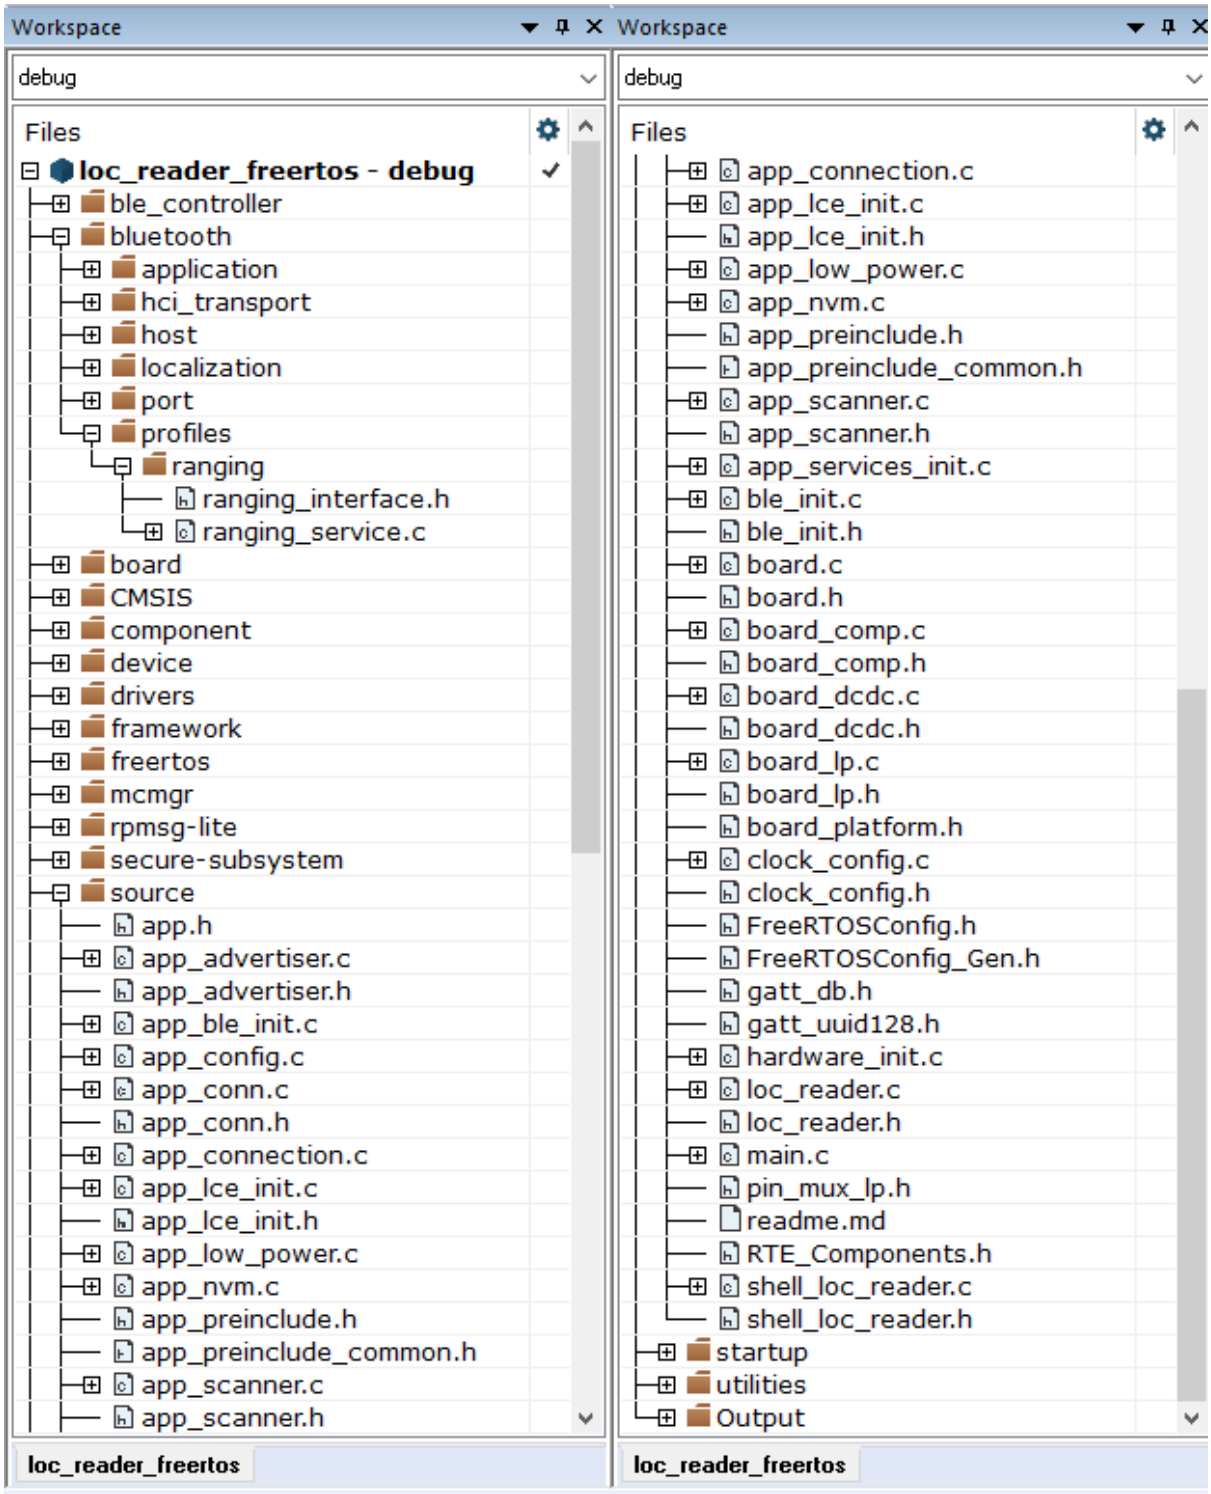
Deploying Bluetooth Low Energy Localization Applications Software

The software package includes the components necessary for Bluetooth Low Energy localization application development on the selected NXP platform. These components include:

- Bluetooth Low Energy Host software libraries
- NBU image binaries
- Channel Sounding and Localization Algorithm libraries
- Examples of sample application project corresponding to Channel Sounding roles, Initiator (Localization User Device), and Reflector (Localization Reader) roles
- Platform peripheral drivers, platform startup code, other generic platform software



Note: Prior to loading any wireless SDK example, update your NBU image with the provided binaries, with channel sounding support, in the following folder of the SDK: ../middleware/wireless/ble-controller/bin.

The demo applications were compiled and tested with **IAR Embedded Workbench** for Arm and **ARMGCC**. Use one of these tools to deploy your sample application.

To open, build, and run any sample application, see the *Bluetooth Low Energy Quick Start Guide* document of the corresponding board. The Bluetooth Low Energy Localization examples are built and run in the same manner as the Bluetooth Low Energy examples.

Figure 1 shows the application folder structure for the loc_reader project for the zip package. The relevant files for Bluetooth Low Energy localization are the following:

- The main application source files are source/loc_reader.c and source/shell_loc_reader.c.
- The files in bluetooth/profiles/ranging implement the Ranging Service.
- The files in source folder contain the Bluetooth Low Energy localization application common code and localization algorithm implementation.

Demo Functionality Overview

The two demo applications provided showcase the following Bluetooth Low Energy localization features:

- Distance measurement through Channel Sounding
- Ranging Service (RAS) and Ranging Profile (RAP) implementation
- Distance measurement data transfer through RAS
- Complex-domain Distance Estimation (CDE) ranging algorithm

- Rapid Accurate Distance Estimator (RADE) ranging algorithm

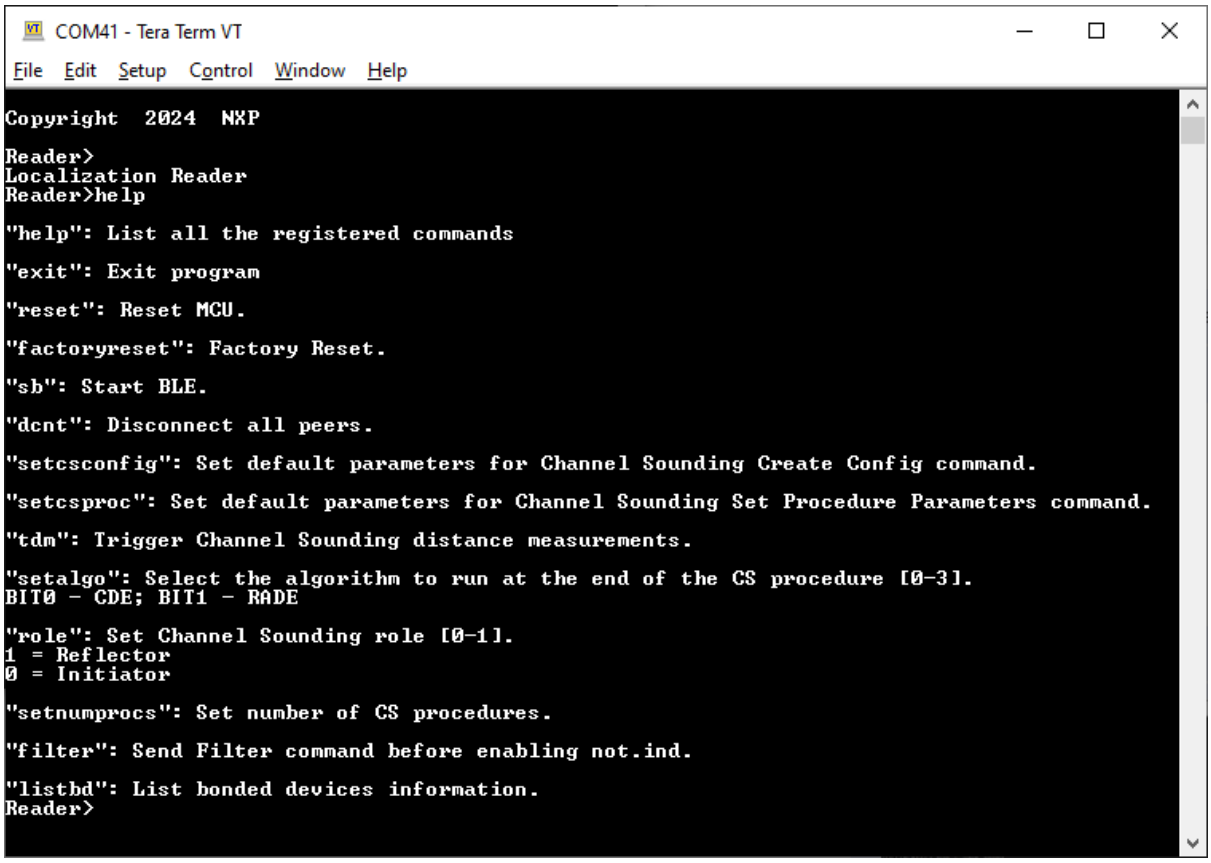
Application configuration options:

- **Channel Sounding role:** Set the Channel Sounding role by using the gCsDefaultRole_c define in app_preinclude.h. In the default configuration, the **loc_reader** application is in the initiator role (gCsRoleInitiator_c) and the **loc_user_device** application is in the reflector role (gCsRoleReflector_c).
- **GATT CCCD type for RAS characteristics:** Configure whether RAS characteristics use INDICATION or NOTIFICATION for data transfer by using the gRasUseNotifOrInd_c define in app_preinclude.h. Set to gCccdIndication_c for reliable delivery with acknowledgment (slower, guaranteed) or gCccdNotification_c for best-effort delivery without acknowledgment (faster, no guarantee). This affects RAS Control Point, Data Ready, Data Overwritten, and On-Demand Data characteristics. Default: gCccdNotification_c.
- **Channel Sounding procedure repeat**: Use the Channel Sounding procedure repeat to specify the number of channel sounding procedures to be performed for each distance measurement triggered. This macro can be set through the gCsProcRepeatMaxNumProcedures_c define.
- **Ranging algorithm**: The ranging algorithm must be run once the local and remote measurement data is available. Both supported algorithms can be disabled at compile time for code size reasons. By default, both are enabled. To disable an algorithm at compile time, define its respective macro with value 0 in the file app_preinclude.h. Use the macros gAppUseCDEAlgorithm_d and gAppUseRADEAlgorithm_d. At runtime, the setalgo shell command can be used to configure the algorithm that runs on completion of the CS procedure and RAS transfer. Any combination of algorithms can be selected.
- **Timing information display**: To enable this feature, set the gAppCsTimeInfo_d macro to the value 1 in the app_preinclude.h file. The console then displays details of the timing information (such as the duration of the CS configuration phase, CS procedure, RAS transfer, and running of the algorithm(s)).
- **Data quality information display**: This feature can be enabled by setting the gAppParseQualityInfo_d macro to the value 1 in the file app_preinclude.h for the Anchor. Additional information (such as RSSI and Tone Quality Indicator values for the measurement data) is displayed in the console.
- **GAP role**: Set the GAP role using gAppIsPeripheral_d, 1 for peripheral role, 0 for central role. In the default configuration, the loc_reader application is central.
- **Maximum concurrent Channel Sounding procedures**: Configure the maximum number of Channel Sounding procedures that can run simultaneously across all connections using the gChannelSoundingMaxConcurrentProcedures_c define in app_preinclude.h.
- **Adaptive Channel Sounding procedure interval (experimental)**: This experimental feature is disabled by default. When enabled (and the procedure auto-restart loop is active), the CS procedure interval is dynamically adjusted between loop iterations based on the remote RSSI average: a good RSSI decreases the interval (faster distance report rate), a bad RSSI increases the interval (more time for the RAS transfer to complete on a weak link), and an RSSI within the hysteresis band leaves the interval unchanged. CS procedures that fail to complete during an iteration are treated as a very bad link. To enable it, set the gAppAdaptiveProcInterval_d macro to the value 1 in the app_preinclude.h file; this requires gAppParseRssiInfo_d to also be enabled (enforced at compile time). The RSSI thresholds and interval limits (gAdaptiveRssiGoodThreshold_d, gAdaptiveRssiBadThreshold_d, gAdaptiveRssiNotCompleted_d, gAdaptiveProcIntervalStep_d, gAdaptiveProcIntervalMin_d, and gAdaptiveProcIntervalMax_d) can be tuned in application/common/lcl/app_localization_config.h.

Running the Bluetooth Low Energy Localization Scenario

To run the Bluetooth Low Energy Localization scenario, flash the **loc_reader** and **loc_user_device** applications on two KW45B41Z-EVK development boards.

Note: The boards listed in *Bluetooth Low Energy Localization Hardware Platforms* can also be used to run the steps listed in this section.



Running a Bluetooth Low Energy Localization Scenario Using the Shell Interface

The following Bluetooth Low Energy localization examples are provisioned by default with a shell command-line interface accessible via a Terminal application such as Tera Term:

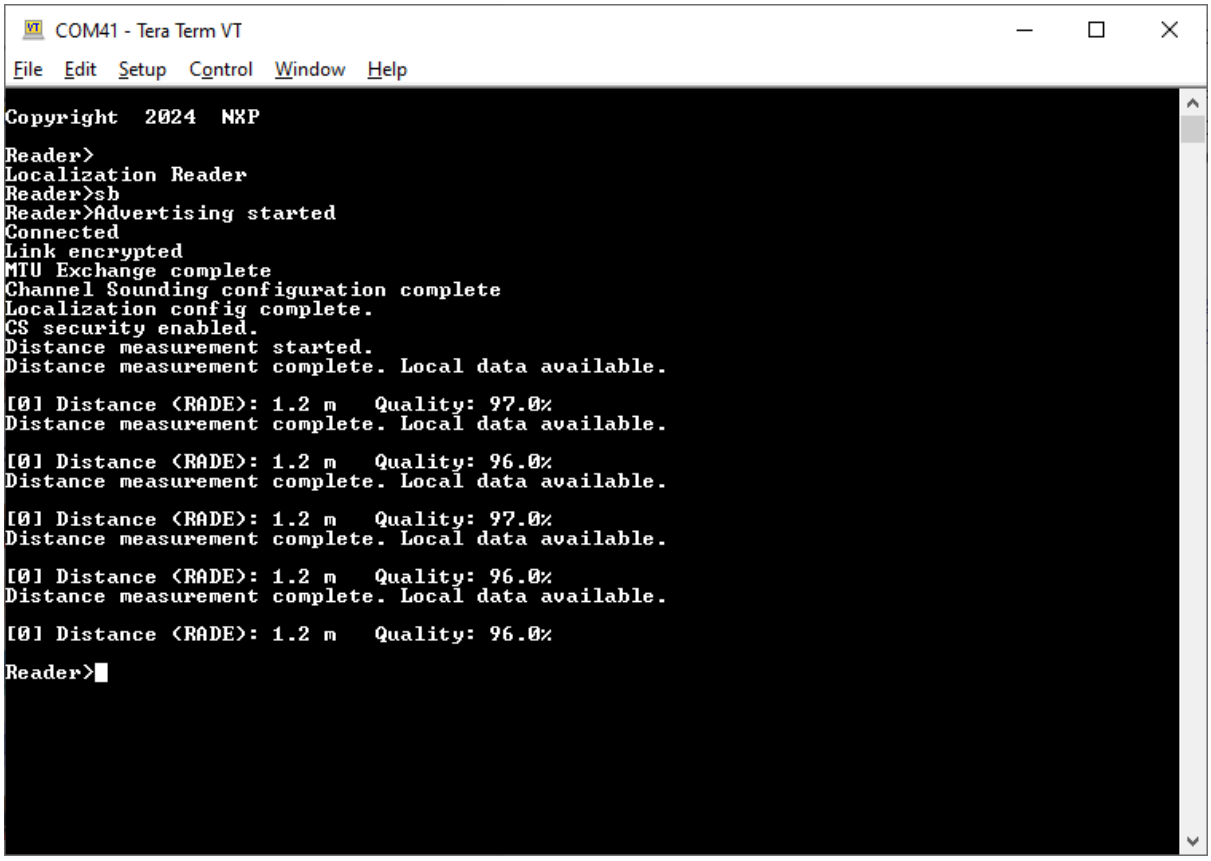
- Localization Reader
- Localization User Device

After connecting with the Terminal application, pressing the **RST** switch on the board displays the application name.

To display the list of available commands and their description, enter the 'help' command as shown in Figure 1.

To run the application, perform the following steps:

- Enter the sb command on both terminals that are connected to the Localization Reader and Localization User Device applications. The devices connect, perform pairing if not previously bonded, and trigger distance measurement.



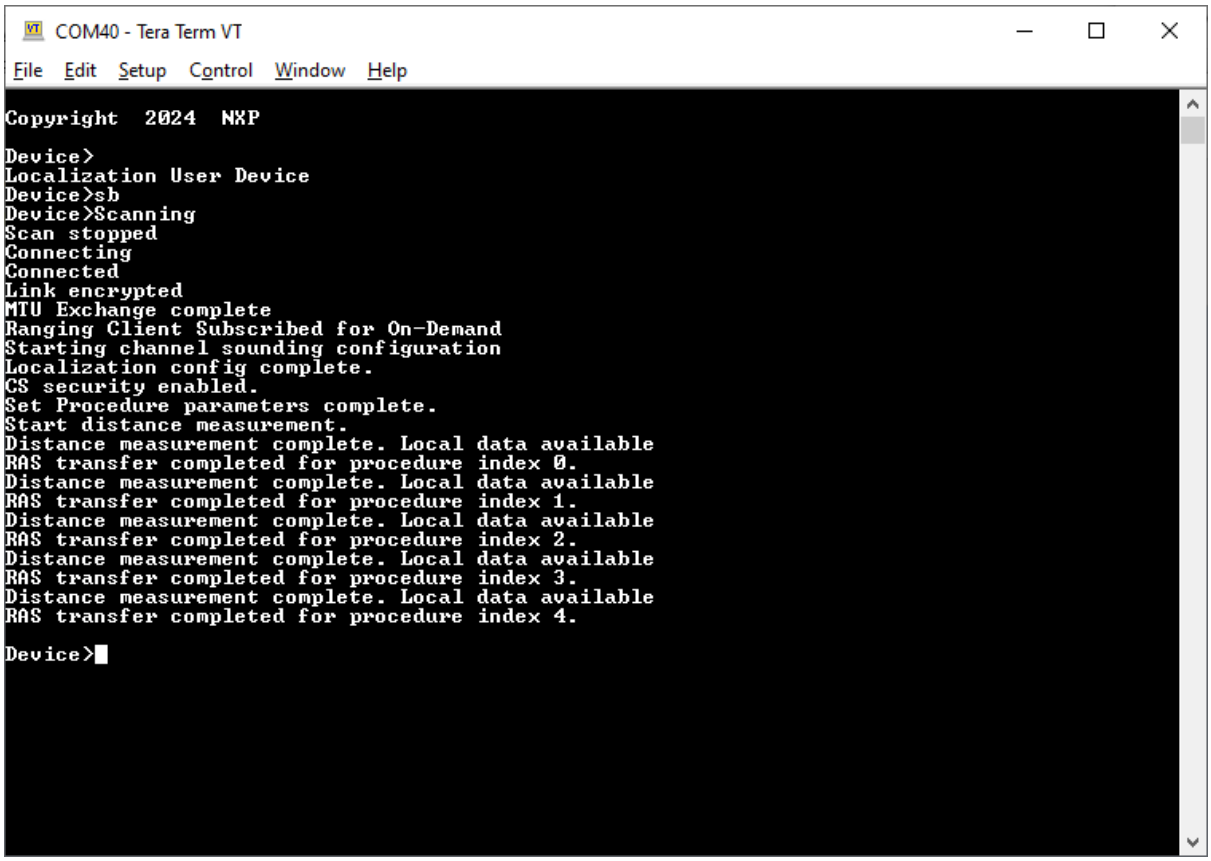


Figure 2 illustrates the start of the Localization Reader application.

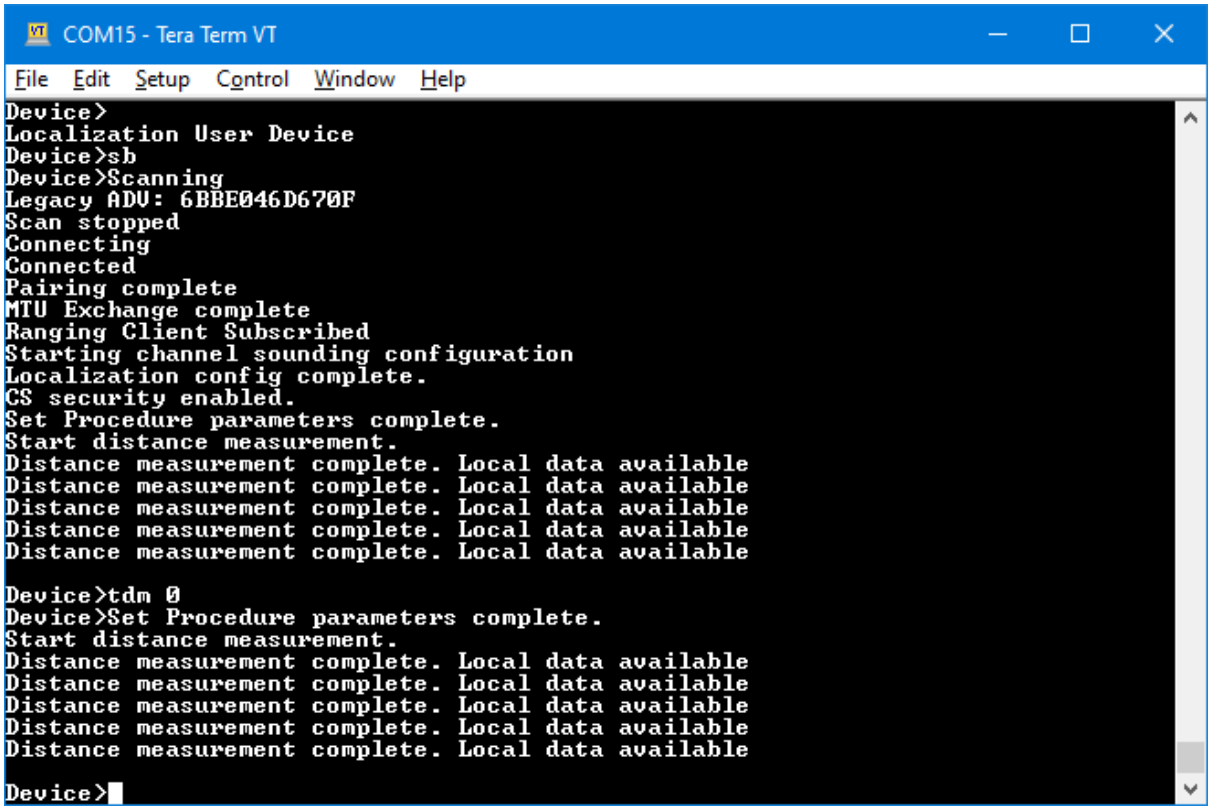

After the devices are connected, the link is encrypted, the Channel Sounding configuration is created, and distance measurement is triggered. This is shown in Figure 3. If two consecutive

distance measurements return a value lower or equal to 1 meter, the LED1 on the Localization Reader starts blinking. If the measured distance is higher than 1, LED1 turns off.

- To trigger a new distance measurement, use the "tdm" command:
  - tdm (without parameters): Triggers distance measurement on **all connected devices**
  - tdm <peerId>: Triggers distance measurement on the **specified peer device**

  Examples:
  - tdm - Start distance measurement on all connected peers
  - tdm 0 - Start distance measurement on peer device with ID 0
  - tdm 1 - Start distance measurement on peer device with ID 1

  This command can be executed on either the Localization User Device or the Localization Reader. Figure 4 shows an example of triggering the distance measurement from the Localization User Device.

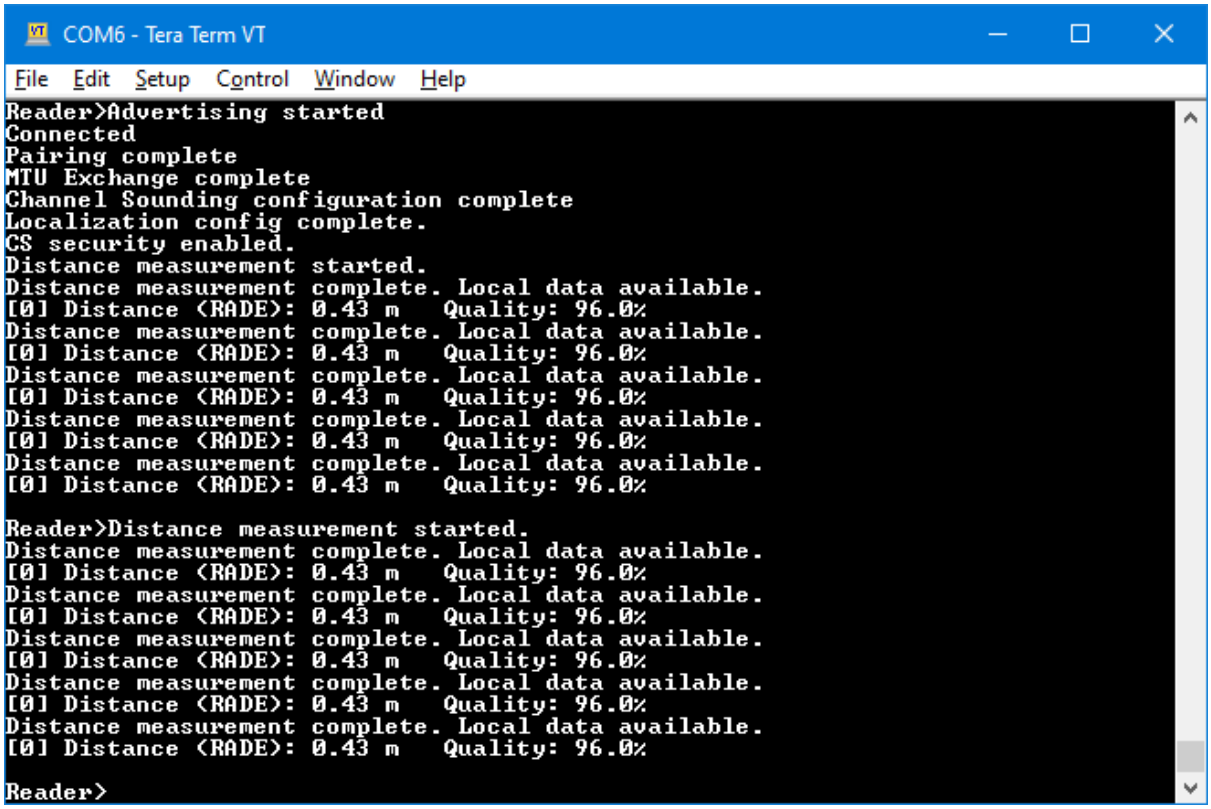

Figure 5 shows the available distance measurement data.

Other available shell commands are:

- setcsconfig: This command overwrites the default parameters for the *Channel Sounding Create Config* command. It updates only the parameters that are explicitly specified; any parameter that is not provided retains its current value. The syntax is:

  setcsconfig <peerId> <paramName> <value> [<paramName> <value> ...]

  where <peerId> is the device ID of the peer, followed by one or more <paramName> <value> pairs. The supported parameter names and their accepted values are:

  - mainmodetype: CS mode to be used as main mode during the CS procedure for this configuration. Possible values:
    - 1 (CS mode-1)
    - 2 (CS mode-2)
    - 3 (CS mode-3)
  - submodetype: CS mode to be used as submode during the CS procedure for this configuration. Possible values:
    - 1 (CS mode-1)
    - 2 (CS mode-2)
    - 3 (CS mode-3)
    - 255 (no submode used)
  - mainmodeminsteps: Lower bound of the range of main mode CS steps to be executed before a submode CS step is executed during the CS procedure. Range:
    - 1 to 255
  - mainmodemaxsteps: Higher bound of the range of main mode CS steps to be executed before a submode CS step is executed during the CS procedure. Range:

    - 1 to 255
  - mainmoderepetition: Number of main mode CS steps repeated from the previous CS subevent at the beginning of the current CS subevent. Range:
    - 0 to 3
  - mode0steps: Number of CS mode-0 steps to be included at the beginning of each CS subevent. Range:\
    - 1 to 3
  - role: CS role. Possible values:
    - 0 (initiator)
    - 1 (reflector)
  - rtttype: RTT variant to be used during the CS procedure. Possible values:
    - 0 (RTT AA only)
    - 1 (RTT with 32-bit sounding sequence)
    - 2 (RTT with 96-bit sounding sequence)
    - 3 (RTT with 32-bit random sequence)
    - 4 (RTT with 64-bit random sequence)
    - 5 (RTT with 96-bit random sequence)
    - 6 (RTT with 128-bit random sequence)
  - channelmap: 80-bit map in big endian order indicating channels to be used for the CS procedure. The default value is fcff7ffcfffffffff1f (all channels used except 0, 1, 23-25 and 77-78). Bit 79 is reserved for future use. At least 15 channels must be enabled.
  - channelmaprepetition: Number of times the channel map will be cyled through for non-mode-0 steps within a CS procedure. Range:
    - 1 to 255.
  - channelselectiontype: Channel selection type. Possible values:
    - 0 (Channel Selection Algorithm #3b)
    - 1 (Channel Selection Algorithm #3c)
  - cssyncphy: PHY to be used for CS_SYNC exchanges during the CS procedure for the specified CS configuration. Possible values:
    - 1 (LE 1M PHY)
    - 2 (LE 2M PHY)
    - 3 (LE 2M 2BT PHY) - if supported at Link Layer level

  Example: setcsconfig 0 mode0steps 3 cssyncphy 2 updates only the mode-0 steps and the CS_SYNC PHY, leaving all other parameters unchanged.

- setcsproc: This command overwrites the default parameters for the *Channel Sounding Set Procedure Parameters* command. It updates only the parameters that are explicitly specified; any parameter that is not provided retains its current value. The syntax is:

  setcsproc <peerId> <paramName> <value> [<paramName> <value> ...]

  where <peerId> is the device ID of the peer, followed by one or more <paramName> <value> pairs. The supported parameter names and their accepted values are:

  - maxprocedureduration: Maximum duration for each CS procedure. Range:
    - 1 to 65535 (units of 0.625ms)

  - minperiodbetweenprocedures: Minimum number of connection events between consecutive CS procedures. Range:
    - 1 to 65535
  - maxperiodbetweenprocedures: Maximum number of connection events between consecutive CS procedures. Range:
    - 1 to 65535
  - maxnumprocedures: Maximum number of CS procedures to be scheduled. Possible values:
    - 0 (CS procedures to continue until disabled)
    - 1 to 65535
  - minsubeventlen: Minimum suggested duration for each CS subevent in microseconds. Range:
    - 1250 microseconds to 3.999999 seconds
  - maxsubeventlen: Maximum suggested duration for each CS subevent in microseconds. Range:
    - 1250 microseconds to 3.999999 seconds
  - antcfgindex: Antenna Configuration Index as described in the Core specification. Range:
    - 0 to 7
  - snrcontrolinit: SNR Control to be applied to the Initiator in the CS procedure (if supported at Link Layer level). Possible values:
    - 0 (SNR control adjustment of 18 dB)
    - 1 (SNR control adjustment of 21 dB)
    - 2 (SNR control adjustment of 24 dB)
    - 3 (SNR control adjustment of 27 dB)
    - 4 (SNR control adjustment of 30 dB)
    - 255 (SNR control is not to be applied)
  - snrcontrolrefl: SNR Control to be applied to the Reflector in the CS procedure (if supported at Link Layer level). Possible values:
    - 0 (SNR control adjustment of 18 dB)
    - 1 (SNR control adjustment of 21 dB)
    - 2 (SNR control adjustment of 24 dB)
    - 3 (SNR control adjustment of 27 dB)
    - 4 (SNR control adjustment of 30 dB)
    - 255 (SNR control is not to be applied)

  Example: setcsproc 0 minsubeventlen 2500 antcfgindex 1 updates only the minimum subevent length and the antenna configuration index, leaving all other parameters unchanged.

- verbosity: Sets the verbosity level during the CS procedure.
- setnumprocs: This command overwrites the default value gCsProcRepeatMaxNumProcedures_c parameter for the CS Procedure Repeat. It takes the following parameters, in the order below:
  - peerId
  - maxnumprocedures: Number of procedures in hex format. Example: setnumprocs 0 0x0005. Value 0x0000 means infinite repeats.

- setmcp: This command overwrites the default value gChannelSoundingMaxConcurrentProcedures_c parameter for the number of maximum supported simultaneous CS procedures across all connections. It takes the following parameters:
  - maxNumConcurrentProcedures: Number of procedures in decimal format. Example: setmcp 2.
- loop: This command toggles the automatic restart of the CS procedure (whether with CS Procedure Repeat enabled or not) upon its end. By default, the CS procedure will not restart automatically.

Parent topic:*Running the Bluetooth Low Energy Localization Scenario*

Running the Bluetooth Low Energy Localization Scenario Using the Button Interface

To run the Bluetooth Low Energy Localization scenario using the button interface perform the following steps:

- Press **SW2** on both boards to connect the devices. After the devices are connected, the link is encrypted and the Channel Sounding configuration is created, distance measurement is triggered. When two consecutive distance measurements return a value lower or equal to 1, the LED1 on the Localization Reader starts blinking. When the measured distance is higher than 1, LED1 turns off.
- Press **SW3** on the *loc_user_device* board to trigger distance measurement. LED1 blinks or turns off, based on the results of the distance measurement.

Parent topic:*Running the Bluetooth Low Energy Localization Scenario*

Selecting the RADE Configuration

The localization examples support four RADE configurations: RADE1, RADE2, RADEX1, and RADEX2. Each configuration is provided as a dedicated Kconfig fragment and is selected at build time using the -DCONF_FILE= west build argument.

Configuration	CONF_FILE value
RADE1	examples/wireless_examples/bluetooth/config/channel_sounding_rade1.conf
RADE2 (default)	examples/wireless_examples/bluetooth/config/channel_sounding_rade2.conf
RADEX1	examples/wireless_examples/bluetooth/config/channel_sounding_radex1.conf
RADEX2	examples/wireless_examples/bluetooth/config/channel_sounding_radex2.conf

To build with a specific configuration, pass the corresponding path to -DCONF_FILE=. For example, to use RADE1:

```
west build -b <board> -- -DCONF_FILE=examples/wireless_examples/bluetooth/config/channel_sounding_
↪rade1.conf
```

Replace channel_sounding_rade1.conf with the desired configuration file name from the table above.

Notes:

- RADE1 and RADEX1 configurations do not use LCE acceleration. Running the RADE algorithm without LCE support increases stack size requirements. Ensure the stack size for the task on which the algorithm runs is at least 4000 octets.
- Make sure that conflicting Kconfig options are not duplicated across configuration files. If duplicates exist, remove them before building the project.

Transient Application Key (TAK)

Overview

The Transient Application Key (TAK) feature provides enhanced security for Bluetooth LE connections between the Localization Reader and Device applications. TAK is a one-time use symmetric key that must be pre-shared between devices before establishing a connection. Once used, the key is automatically erased per specification requirements. This guide provides out-of-the-box commands ready for copy-paste into TeraTerm.

Prerequisites

Ensure both applications are compiled with TAK enabled (gAppUseTAK_d = 1) and gAppTAKAdvID_c matches on both sides. The default configuration supports up to 4 TAK entries (gConnTakMaxEntries_c = 4). In order for Peripheral to allow passing LTK request (coming from an unbonded device) to the application, gBleHostAutoRejectLtkRequestForUnbondedDevices_c must be set to FALSE in the loc_user_device application. Because TAK is not considered sufficient method for an attribute which requires encryption, all encryption-related flags from the database must be removed. Check gatt_db.h, on the loc_user_device and remove the flags gPermissionFlagWriteWithEncryption_c and gPermissionFlagReadWithEncryption_c.

Quick Setup

Setup on Localization Reader

tak 0 00112233445566778899aabbccddeeff sb

Setup on Localization Device

tak 0 00112233445566778899aabbccddeeff sb

For Subsequent Connections

Since TAK is erased after use, set a new key before the next connection: tak 0 11223344556677889 9aabbccddeeff00

Typical Console Output

Testing RAS and RAP using Profile Tuning Suite (PTS)

When testing RAS and RAP using the PTS, the loc_reader and loc_user_device need to be used.

The test code support for testing RAS and RAP against PTS is located in the files:

- application/common/lcl/app_localization.c
- application/common/lcl/pts_test_vectors.c
- examples/loc_reader/loc_reader.c
- examples/loc_user_device/loc_user_device.c

This configuration must be enabled in the app_preinclude.h of either of the examples:

- gRasRapPtsTest_d is set to 1
- gAppUsePrivacy_d is set to 0
- gRandomStaticAddress_d is set to 0
- gAppMaxConnections_c is set to 2 (any value higher than 1)

The testing method for RAS and RAP in PTS is based on a test vector approach, as PTS does not support Channel Sounding (CS).

Usage

The PTS tool implements tests using test steps. These steps could vary from connects and disconnects, to generation and injection of CS data in the Implementation Under Test (IUT).

The test steps require user interaction with the IUT, as PTS will guide the user with actions necessary for the user to execute to complete the test.

Primarily, the user will use the:

- sb command to start Bluetooth LE advertising for the PTS to initiate a connection to the IUT.
- dcnt command to disconnect the IUT from the PTS.
- ptstest command, followed by the test_id that is the id of the test running, usage example: ptstest RAS/SR/RCO/BV-01-C.
- filter command set a filter. (used in reduced number of test)

A test could require no use of the ptstest, one use of the ptstest command or multiple uses of the ptstest command. When a test requires a user to perform several actions, ptstest test_id should be issued with the same test ID as the test being run. The test step logic can be found in the loc_reader.c and loc_user_device.c, under the BleApp_RunPtsTest function.

Bluetooth Low Energy Channel Sounding Application Developer’s Guide Introduction

Channel Sounding (CS) is a Bluetooth Low Energy version 6.0 feature which, together with the Ranging Service (RAS)/Ranging Profile (RAP), enables two devices to securely estimate the distance between them.

The devices have the following roles:

- within GAP, one device is a Peripheral, the other is a Central.
- within CS, one device is the CS Initiator, the other is the CS Reflector.
- within RAS, one device is the Ranging Requester, the other is the Ranging Responder.

The role configurations above are described in detail in the following sections.

This document explains how to integrate CS and RAS/RAP functionality into an application and provides detailed explanation of the most commonly used APIs and code examples.

Prerequisites

Channel Sounding functionality can be integrated into an application that fulfills the following requirements:

- Supported platforms: KW47-EVK, KW47-LOC, KW43-LOC, FRDM-MCXW72, MCX-W72-EVK, MCX-W72-LOC and FRDM-KW43.
- Bluetooth Low Energy application that uses the lib_ble_OPT_host_cm33_iar/gcc.a Host library and the lib_channel_sounding_iar/gcc.a library.

Integration

The Channel Sounding functionality at Host level is implemented in the following libraries:

- lib_channel_sounding_iar.a (for IAR projects)
- lib_channel_sounding_gcc.a (for MCUX or armgcc projects)

All the Channel Sounding APIs can be found in middleware\wireless\bluetooth\host\interface\channel_sounding.h.

Application common modules

While the CS APIs are available to applications and can be used directly, common application modules are also provided. These modules, detailed below, offer a simplified API for performing distance measurements and allow for quick integration into existing applications.

app_localization common module

Introduction

The app_localization common module allows for quick integration of Channel Sounding functionality in a Bluetooth LE application.

Integration

All the APIs referenced in this section are available in the app_localization application common module.

Perform the following steps for integration into the application. Unless specified, each step applies to both the CS Initiator and the CS Reflector:

1. Add the following components to the application project via Kconfig:
   - CONFIG_MCUX_COMPONENT_middleware.wireless.lcl=y
   - CONFIG_MCUX_COMPONENT_middleware.wireless.ble_host_CS=y
   - CONFIG_MCUX_COMPONENT_middleware.wireless.ble_host_CS_component_lib=y
2. Begin the initialization of the common module by calling AppLocalization_Init(). One of the parameters of this API is the application callback where events will be received from the app_localization module.
3. Complete the initialization of the common module by calling AppLocalization_HostInitHandler() after the Host stack has been initialized.
4. The CS Config depends on the Bluetooth LE connection interval. Upon connection with the peer, the CS Config is retrieved by calling AppLocalization_ReadConfig() and updated by calling AppLocalization_WriteConfig().
5. If the application is the Ranging Requester, that is, it will run the distance measurement algorithm, the connection interval must also be saved by calling the function AppLocalization_SetConnectionInterval(). This is required by the algorithm.
6. Once the Ranging Requester has discovered and subscribed to the Ranging Service on the Ranging Responder (as detailed in the section below), the CS procedure can begin. The first step is to call AppLocalization_Config().
7. Upon receiving the gConfigComplete_c or the gLocalConfigWritten_c events, only the device who has the GAP Central role must call AppLocalization_SecurityEnable().
8. Upon receiving the gCsSecurityEnabled_c event, only one device must call AppLocalization_SetProcedureParameters().
9. Upon receiving the gSetProcParamsComplete_c event, the device from step 8 must call AppLocalization_StartMeasurement().
10. From this point onwards, the application will receive events informing it of the status of the distance measurement procedure, such as:

- gDistanceMeastStarted_c - the CS Procedure has started
- gLocalMeasurementComplete_c - the CS Procedure is complete and local data is available
- various error events

11. Upon peer disconnection, cleanup should be performed by calling AppLocalization_ResetPeer().

Parent topic:*Application common modules*

app_localization_algo common module

Introduction

The app_localization_algo module is responsible for unpacking the data resulted from the CS Procedure and the RAS transfer. The module then passes it to the distance measurement algorithm to obtain the distance in meters, which is then communicated to the application.‘

Integration

The app_localization_algo is only required on the application that has the role of Ranging Requester and computes the actual distance. Perform the following steps to integrate app_localization_algo common module:

1. Add the following component to the application project via Kconfig:
   - CONFIG_MCUX_COMPONENT_middleware.wireless.lcl_algo=y
2. Pass a callback of type pfAppDisplayResult_t as the third parameter of AppLocalization_Init. This callback receives the distance measurement result, which the application displays.
3. Call the function AppLocalizationAlgo_ResetPeer upon peer disconnection to clean up algorithm-related data structures.
4. There is no other direct interaction between the application and this module. Its APIs are mostly used by the app_localization module.

Ranging Service common module

Introduction

The Ranging Service is a GATT service used to transfer the data resulted from the CS Procedure from one device (the Ranging Responder) to the other (the Ranging Requester).

Integration

Perform the following steps to integrate the Ranging Service on the application that has the role of Ranging Requester (GATT client):

1. Add the following component to the application project via Kconfig:
   - CONFIG_MCUX_COMPONENT_middleware.wireless.ble_profiles_ranging_client=y
2. Ensure the gRasRREQ_d define is present and set to 1 in the application’s app_preinclude.h file.
3. After the connection with the peer is encrypted, proceed to discover the RAS and its characteristics through the common Service Discovery module. Register a service discovery callback using BleServDisc_RegisterCallback and call BleServDisc_FindService() with the gBleSig_RangingService_d UUID as parameter. On the gServiceDiscovered_c event in the registered callback, store the handles of the RAS and its characteristics and characteristic descriptors for later use. Some handles also need to be registered with the localization component via the following APIs:

1. RasClient_SetRasControlPointHandle
2. RasClient_SetRasRealTimeHandle
3. RasClient_SetRasSupportedFeatures

4. Proceed to use the regular GATT client APIs such as GattClient_ReadCharacteristicValue() and GattClient_WriteCharacteristicDescriptor() in order to read the peer's supported RAS features and enable notifications/indications on the RAS Control Point CCCD and on either the On-Demand or Real-Time CCCDs. If you choose On-Demand as a data transfer method, you must also enable notifications/indications on the RAS Data Ready and Data Overwritten CCCDs. The client is now considered subscribed to the RAS and the CS Procedure can start by following the steps described in the sections above.
5. Depending on the RAS settings chosen by the client application, communication from the server arrives as either GATT notifications or indications. In the GATT notification or indication callback, the following APIs should be used:
    1. RasClient_StorePeerMeasurementData, when the On-Demand or Real-Time handle is notified/indicated.
    2. RasClient_ProcessRasCPRsp, when the Control Point handle is notified/indicated.
    3. RasClient_ProcessRasDataReadyIndications, when the Data Ready handle is notified/indicated.
    4. RasClient_ProcessRasDataOverwrittenIndications, when the Data Overwritten handle is notified/indicated.

Perform the following steps to integrate the Ranging Service on the application that has the role of Ranging Responder (GATT server):

1. Add the following component to the application project via Kconfig:
    - CONFIG_MCUX_COMPONENT_middleware.wireless.ble_profiles_ranging=y
2. Ensure the gRasRRSP_d and gAppRasDataTransfer_d defines are present and set to 1 in the application's app_preinclude.h file.
3. Add the Ranging Service and its characteristics to the GATT database in the application project's gatt_db.h file as in the excerpt below:

```
PRIMARY_SERVICE(service_ranging, gBleSig_RangingService_d)

```

4. Initialize RAS by calling Ras_Start() with the handles defined in the GATT database.
5. Upon the MTU Exchange procedure's completion, call Ras_SetMtuValue() to inform the module.
6. The client's interactions with the server are processed in the GATT server callback. Here the following APIs are used:
    1. Ras_Subscribe when the client subscribes to either On-Demand or Real-Time CCCDs.
    2. Ras_SetDataSendPreference to save the client's preference for the data transfer (either notifications or indications).
    3. Ras_ControlPointHandler when the client writes a command to the RAS Control Point.
    4. Ras_Unsubscribe when the client unsubscribes or disconnects.

Distance Measurement Algorithm

Introduction

The SDK provides the RADE (Rapid Accurate Distance Estimator) algorithm for precise distance measurement between devices. This algorithm leverages the LCE (Localization Compute Engine) accelerator to calculate distances with high accuracy and low latency.

Integration

Perform the following steps to integrate the RADE algorithm on the distance-measuring application:

1. Add the following components to the application project via Kconfig:
    - CONFIG_MCUX_COMPONENT_middleware.wireless.rade2_algo_cm33_lce_lib=y
    - CONFIG_MCUX_PRJSEG_module.board.wireless.app_lce=y
    - CONFIG_MCUX_PRJSEG_module.board.wireless.linker_script_ble=n
    - CONFIG_MCUX_PRJSEG_module.board.wireless.linker_script_ble_loc=y
2. APP_InitLce() will be automatically called by AppLocalization_Init() during application initialization.
3. Heap areas required by the algorithm are defined and registered in app_lce_init.c.

Bluetooth Channel Sounding technique for distance estimation Introduction

The low-power 2.4-GHz ISM band wireless standards, such as Bluetooth 2 The channel sounding standard Low Energy (BLE), have broad adoption in consumer products such as smartphones, tablets, smartwatches, or edge nodes in Internet of Things (IoT) networks. As the application domains of the BLE technology expand into industrial and automotive markets, their mass adoption and omni-presence makes this technology usable for applications that go beyond data transfer between devices. The radios included in these products can be used for more complex use cases, such as distance estimation, angle (of arrival/departure) computations, and localization applications. They span the joint estimation of both the angle and the distance when used with specialized hardware enabled as anchors.

This document describes the distance measurement between 2 Bluetooth LE devices using NXP MCUs. This solution only applies to Bluetooth LE devices. This document refers to the KW47 and KW43 MCU and its associated SDK. The SDK also contains the Wireless Localization middleware, which uses a special distance-estimation technique called Channel Sounding (CS). By enabling the CS feature between Bluetooth devices, a measured channel response can be used to calculate the position of a Bluetooth device in a high accuracy mode (at a distance of 5 m with an accuracy of ± 0.5 m in ideal conditions). Channel sounding verifies whether a device is in a predefined area, which makes beacons easier to install and improves indoor localization. Deriving a distance estimate using CS requires 1 device to initiate the process (initiator) and a 2nd device to reciprocate the transmission (reflector). The Measuring Device (MD) and Reflector Device (RD) terms are also used. This solution does not require multiple antennas (but can benefit from their presence) to compute the distance between 2 nodes. There are many aspects to consider when creating a localization solution that meets unique requirements. This application note highlights the aspects that impact performance with a focus on how to use NXP enablement to create your own solution. This document also refers to the following documents for localization purposes:

- Channel Sounding Wireless Ranging Demo Application
- KW47 Ranging Performance Measurement
- KW47-LOC Board User Manual
- KW43-LOC Board User Manual
- FRDM-KW43 Board User Manual

This application note describes a method to estimate the distance partly based on Round-Trip Phase (RTP) measurements. The legacy name of the RTP is Phase-based Distance Estimation (PDE). The phase of RF signals is proportional to the frequency of the carrier and the distance traveled. The method is based on measuring the received signals' phases relative to their local oscillators. The measurements are then performed using tone signals at different frequencies and combined for a final distance estimation.

A part of the description incorporates a method of measuring the Round-Trip Time (RTT) of the RF signal. The legacy name of the RTT is the Time of Flight (ToF) distance estimation. This measurement has lower accuracy when compared to the phase measurement. However, it has an inherent advantage of adding security. The security aspect is described as well.

Bluetooth Channel Sounding high-level requirements

This chapter provides several aspects of CS requirements for localization demands. The distance-measurement accuracy is divided into 2 categories. The measured channel response can be used to calculate the position of a Bluetooth device with the high accuracy mode - defined at a distance of 5 m with an accuracy of ± 0.5 m.

The CS also defines conditions for non-stationary devices with the maximum relative speed between the initiator and the target. The maximum absolute speed of either device is less than or equal to 5 km/h (typical walking speed). The device should be capable to make at least 2 distance measurements per second to realize real-time distance estimation to an object moving at a speed of 5 km/h.

The immunity to relay attacks is also part of the CS specification. The mitigation of both packet and extender relay attacks is at least as cryptographically strong as a link layer encryption. The link layer security must be enabled as a prerequisite for channel-sounding operations. The protection against symbol manipulation attacks is covered by the resiliency to the Early Detect Late Commit (EDLC) and symbol attacks on the RTT packets. This is provided by symbol sharpening and shortening.

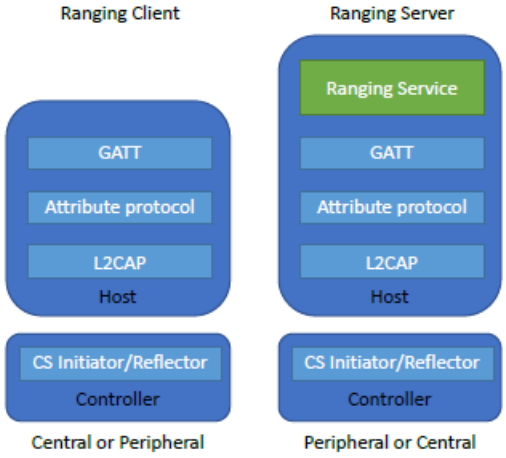
Another requirement defines the attack detection in terms of distance estimation. The CS should detect an attack in which the distance measurement is spoofed by more than:

- 3 m for distances of up to 15 m
- 20 % of the total distance for distances greater than 15 m

The channel sounding standard description

This chapter focuses on the Channel Sounding (CS) standard description. The CS feature consists of a combination of software link layer procedures and dedicated air interface protocol that creates a tightly interlocked exchange of RF signals at multiple RF channels. This mechanism is called a CS procedure. Before describing it, it is important to describe the high-level software architecture.

Software layers architecture description



To enable the CS feature between 2 Bluetooth devices, a general service is proposed. In this service, the client and server roles are defined. Typically, the client role in the service is the CS initiator and the server role is the CS reflector. However, there is also a scenario, where the client role is the CS reflector and the server role is the CS initiator. The complete list of scenarios is shown in Table 1.

Table 1. Scenarios for ranging server and ranging client

	Scenario I		Scenario II	
Host Controller	Ranging Client Initiator	Ranging Server Reflector	Ranging Client Initiator	Ranging Server Reflector

The Ranging Server (RAS) and Ranging Profile (RAP) enable the CS configuration parameters and CS results transport toward the Distance Measurement Application. The complete exchange of unmodulated carrier signals and/or packets is controlled by lower Bluetooth protocol layers (Bluetooth controller).

The high-level SW architecture of the ranging server and ranging client

The ranging client and ranging server must exchange their capabilities via the RAS capabilities characteristic. The ranging client writes (or reads) the configuration to the Ranging Server through the RAS configuration characteristic. Then, the 2 controllers start the ranging procedure. Once the ranging results are received by the RAS from the controller, the results will be exchanged using GATT toward the Distance Measurement Application. Some implementations may optionally use the enhanced attribute protocol to make notifications more reliable. The roles defined in the ranging service and profiles are as follows:

- Ranging client: the device in this role supports the GATT client role and optionally the enhanced attribute protocol and the CS initiator or reflector roles The ranging client can have either the central or peripheral roles. The ranging client has a direct interconnection with the Distance Measurement Application.

- Ranging server: the device in this role supports the ranging service and profile. It implements the GATT server role and optionally the enhanced attribute protocol role. In the controller, it implements the CS reflector or initiator roles. The ranging server has either the central role or the peripheral role. The ranging server assists the ranging client by sending the local device capability, receiving the ranging client configurations, and sending the ranging result toward the ranging client.

The Distance Measurement Application will be implemented in the device that supports the ranging client. The hosts may support both the ranging client and ranging server implementations. The higher layer will choose which device runs the distance application and becomes the ranging client. Figure 1 illustrates the high-level architecture of the ranging server and ranging client for 2 scenarios listed in Table 1. In the asset-tracking and indoor-positioning applications, the distance measurement application may calculate the distance between:

- A ranging client and more than one ranging server
- A ranging server and more than one ranging client

The CS standard (the part of the ranging server and ranging profile) also mentions examples of the typical application use cases. Table 2 shows several typical localization applications.

Table 2. Localization user scenario examples

User Scenario	Ranging Client	Ranging Server
Vehicle access	Vehicle Bluetooth LE lock (single Bluetooth LE initiator, an initiator with multiple antennas, or multiple initiators each with a single antenna or multiple antennas)	Vehicle key (can be a phone)
Door access	Door Bluetooth LE lock	Door key (can be a phone)
Locate lamps, sensors, and actuators during commissioning or maintenance	Handhold commissioner	Other lamps/sensors
Locate items with a smartphone	Bluetooth LE localization system (1 initiator or multiple initiators)	Tags
Locate items with a handheld locator device	Handhold with Bluetooth LE	Tags
F: Automatically map mesh nodes	Some/all lamps must support dual roles (initiator and reflector devices)	Some/all lamps must support dual roles (initiator and target devices)
G: Cooktop control	Cooktop	Smartphone
H: Cooktop safety	Cooktop	Smartphone

Note: The CS standard itself is not responsible for computing the distance measurement

Parent topic:*The channel sounding standard description*

The channel sounding procedure description

The CS procedure consists of several events that are defined as a set of time and frequency slots, in which 2 devices agree to communicate and exchange a combination of RF signals. The main purpose of this exchange is to estimate the physical characteristics of the transmission channel. These exchanges are always bidirectional.

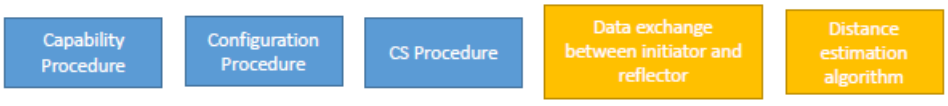
The CS procedure is divided into one or more events. The CS event can consist of one or more CS steps that are separated by a frequency change period called T_FCS. Time separation between

CS events avoids continuous allocation of the RF resources of a given device and facilitates coexistence with other RF technologies. Figure 2 shows the relationship between CS procedures, CS events, and CS steps.

Channel Sounding procedure composition

Each CS event has a separate anchor point labeled 'X'. The link layer configures devices to run this procedure. It defines all the steps for these events in both time and frequency relative to these anchor points. The output of the CS procedure is a table of phase correction terms for both the initiator and the reflector and/or a table of time stamps. The processing algorithms translate those tables into distance estimates. The processing algorithms are not part of the standard. The procedure is composed of one or more CS events. The CS event is composed of the multiple CS steps. There can be programmable gaps between CS events to allow other simultaneous connections.

Four CS step types (mode 0, mode 1, mode 2, and mode 3) are defined. Each mode is used for a specific purpose:



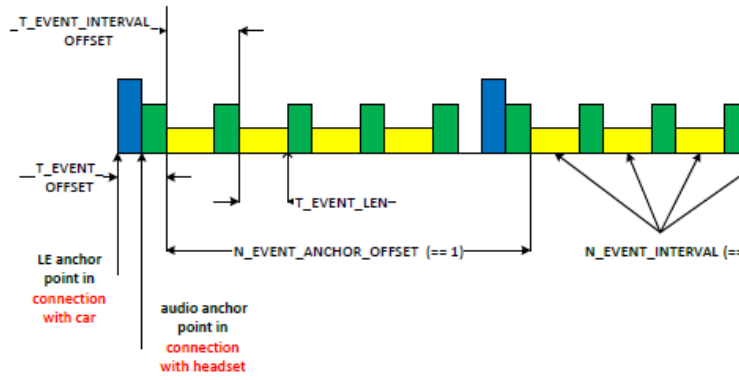
- Mode 0 is used to calibrate 1 side to the other in terms of frequency and timing.
- Mode 1 is used to exchange a Round Trip Timing (RTT) packet.
- Mode 2 is used to exchange Round Trip Phase (RTP) packets and to measure the phase and amplitude of the communication channel.
- Mode 3 is used to exchange both RTT and RTP measurement packets.

In the CS context, an initiator is the device that starts (initiates) the whole procedure and a reflector is the device that responds to (reflects) the CS procedure. The procedure's operating parameters are exchanged via link layer control messages. Once the procedure completes, each device has a set of information that describe the real communication channel. Mode 1 and mode 3 measure the time of arrival and the time of departure. Mode 2 and mode 3 measure the phase and amplitude information in the form of in-phase (I) and quadrature-phase (Q) components. The reflector communicates this information back to the initiator. The following chapters describe 4 different step types.

Parent topic:*The channel sounding standard description*

The CS high-level view

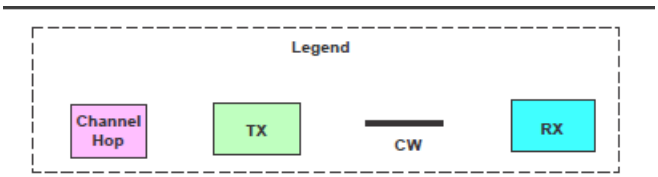
The high-level view of the several procedures needed for the distance estimation is shown in **Distance estimation - high-level view**



. A simple flowchart shows the procedures described in the CS standard. It also contains yellow boxes, which are not directly defined by the CS standard. The data exchange between the initiator and the reflector cover for example the IQ data, RTT timestamps, and so on. The data exchange is planned to be a part of the ranging service profile.

Distance estimation - high-level view

The example of the CS events interleaved with LE connection events is shown in Figure 4. This should improve the understanding how the CS events are interleaved with the LE connection events. The CS events are scheduled at an offset from the LE connection anchor points. Only 1 CS event is scheduled in this scheme. As an example, a smartphone in a key fob role may be connected to an automobile for localization purposes. The connection interval of this LE connection may be very long, because its main purpose is to start CS procedures.



CS event scheduling in coexistence scenario

At the same time, the phone may be connected to a headset for audio connection purposes. To allow for flexible scheduling of CS events, multiple CS events can be scheduled offset from single LE connection events. A CS event offset is used to separate the multiple CS events in time. The number of CS events allowed in between LE connection events is selectable.

Parent topic:*The channel sounding standard description*

Channel Sounding steps description

The CS defines a set of interlocked transfers between initiator and reflector. Within a CS procedure, CSStepCount shall be set to the current CS step number. The CS steps are constructed by a combination of modulated and unmodulated RF signals. The modulated sections convey synchronization information and extract the round-trip time information. The unmodulated sections are used to measure the phase rotation, which is proportional to the distance between the devices. The CS steps use the dedicated packet formats. There are 4 different modes for the CS steps. Each of these modes has different usage goals: measuring frequency offset between devices (mode 0), measuring round-trip times (mode 1), measuring phase rotations due to distance (mode 2), and measuring both round-trip times and phase rotations (mode 3). The CS steps require a precise timing synchronization between the initiator and reflector devices. Figure 5 shows a legend of the diagrams used in the following chapters to describe individual CS step modes.

Legend for CS step type packet description

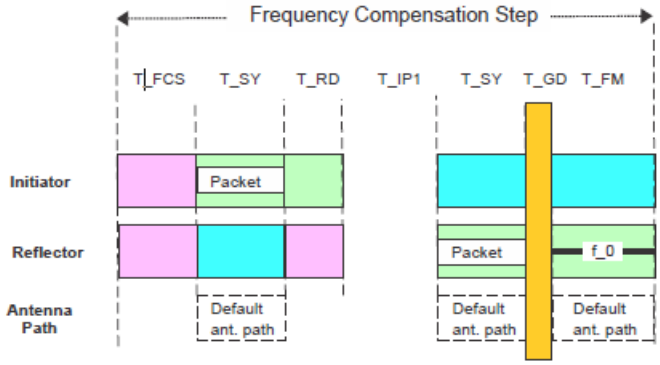
The colored time slots represent the following:

- Channel Hop time slot
- TX - transmitting time slot
- CW - unmodulated continuous wave signal
- RX - receiving time slot

The CS steps are separated by periods to perform a frequency hop. The structure is shown in Figure 6.

Channel hop period separates CS steps

The time for the frequency hop is known as T_FCS. The initiator and reflector devices exchange the list of T_FCS values that each one can support during the capability procedure. The initiator selects a common T_FCS value during the configuration procedure. The permitted values for T_FCS are given by the BLE standard. Within a CS procedure, the same T_FCS value should be used for each channel hop. Both devices use the T_FCS period to perform internal calibrations in addition to the frequency change. The initiator or reflector may use this time period to allow the settling of the transmitted RF signal. It means that it reached a stable state when the subsequent CS step begins.



The set of variables used in the following chapters describes the CS step modes, as shown in Table 3.

Table 3. Channel Sounding step variables

Variable	Description	Time duration [us]
T_FC	Time for frequency change spacing. The RF circuitry locks to the measurement channel (f_i). Devices can also use this time for additional internal calibrations, if necessary. The initiator may start to ramp up its output signal toward the end of this step	15, 20, 30, 40, 50, 60, 80, 100, 120, 150
T_FM	Time for frequency measurement	80
T_SY	Time for synchronization sequence (CS packet)	26 for 2M PHY, 44 for 1M PHY
T_IP	Interlude period 1. The transition from TX to RX and the other way around when transmitting in mode 1 (Pk-Pk).	10, 20, 30, 40, 50, 60, 80, 145
T_IP	Interlude period 2. The transition from TX to RX and the other way around when transmitting in mode 2 (Tn-Tn).	10, 20, 30, 40, 50, 60, 80, 145
T_GI	Transition time between packet and tone	10
T_RI	Ramp-down time for transmission	5
T_PM	Single-antenna phase measurement period	10, 20, 40
N_A	Number of antenna paths	1, 2, 3, 4
T_SW	Antenna switching period	1, 2, 4, 10
N_A	Phase measurement period. This measurement must be performed for each antenna path. N_AP is the total number of antenna paths. Transmitted signals are expected to be stable during this period. When multiple antenna paths are used, an equivalent number of T_PM periods is used. Each T_PM reserves the first 2 us for antenna switching (T_SW).	-

CS step mode 0

TCS step mode 0 is used to measure the frequency offset between the initiator and the reflector at a given frequency. The step mode 0 is a basic step supported by all the devices with CS feature. Figure 7 shows the exchange defined for CS step mode 0.

CS step Mode 0 packet exchange

The frequency hop is created before each CS step. The initiator starts by transmitting the CS SYNC packet (T_SY). The duration of the packet is shown in Table 3. The initiator performs a measurement of the frequency offset from the transmitted RF signals from the reflector during CS step mode 0. The initiator shall use this information to compensate all further transmissions within the subsequent CS steps in a CS event. This is used for synchronization purposes.

After the transmission from the initiator completes, a defined ramp-down window of 5 us (T_RD) is allowed for the initiator to remove the transmitted energy from the RF channel. After T_RD, the output power shall be lower by 40 dB than the output power used during the transmission of the CS SYNC packet (measured at the initiator's antenna).

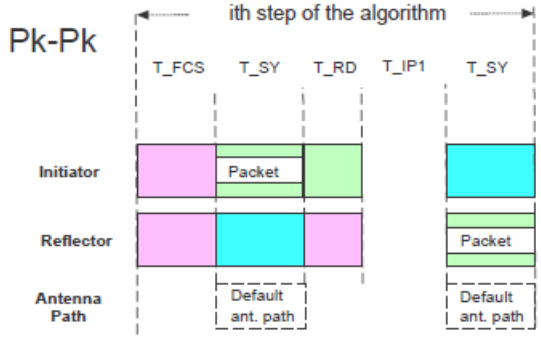
T_IP1 represents the idle time between the transmission from the initiator and the transmission from the reflector. Devices may use this time for internal calibrations, if needed. The reflector can use this time to ramp up its transmitted signal (if necessary) in advance of the transmission of the CS SYNC packet (T_SY) with the unmodulated carrier after synchronization. A transition time from packet to tone (T_GD) is needed. Then the reflector device makes the frequency-measurement period. The duration of this period (T_FM) for CS mode 0 shall be 80 us. The frequency measurement period ends the CS step mode 0 procedure.

It is important to mention 2 packet formats for channel sounding. Channel sounding uses a specific modulated bit sequence known as CS SYNC. The CS SYNC packet format is similar to a packet format for uncoded PHY, but it has no CRC. The CS SYNC packet has a specific format shown in Figure 8.

CS SYNC packet format

Preamble (1 or 2 octets)	CS Access Address (4 octets)	Trailer (4 bits)	Sounding Sequence (32 or 96 bits) Or Random bit sequence (32, 64 or 128 bits)

The preamble is 1 octet when transmitting or receiving on the LE 1M PHY and 2 octets when transmitting or receiving on the LE 2M PHY. The CS access address is 4 octets. The trailer is 4 bits. The sounding sequence or random bit sequence are optional fields. If present, the sounding sequence shall be 32 or 96 bits long. If the random bit sequence is present, it shall be 32, 64, or 128 bits long.



The variable length of the optional sounding sequence and random bit sequence allows an implementation to optimize the total packet length vs the correlation accuracy of the field. CS packets with no sounding or random bit sequence take 44 us to transmit when sent by LE 1M PHY and 26 us to transmit when sent by LE 2M PHY. CS packets that include a sounding or random bit sequence take proportionally longer to transmit, based on the length of the field and the PHY selection.

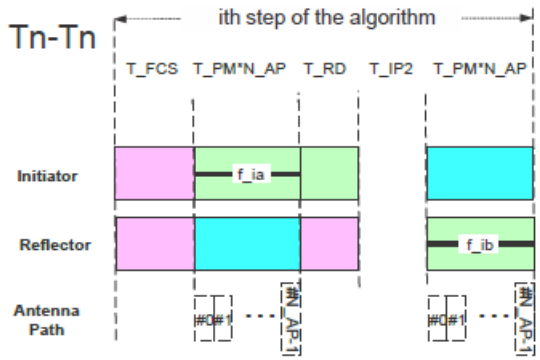
Parent topic: The channel sounding steps description

CS step mode 1

CS mode 1 is used to measure the round-trip time between the initiator and the reflector. Devices supporting the CS feature shall implement the CS step mode 1. This mode uses the theoretical background described in RTT estimation fundamentals. The packet structure in Figure 9 is defined for CS step mode 1. Before each CS step, a frequency hop is created

CS step mode 1 packet exchange

The initiator starts by transmitting the CS SYNC packet. The duration of the CS SYNC packet is marked as T_SY. In this case, CS step mode 1 may include a payload as part of the CS SYNC packet. After the transmission from the initiator completes, a defined ramp down window of 5 us is allowed. It helps the initiator to remove the transmitted energy from the RF channel. After the ramp down, the output power shall be lower by 40 dB than the output power used during the transmission of the packet, measured at the initiator's antenna.



T_IP1 represents the idle time between the transmission from the initiator and the transmission from the reflector. Devices may use this time for internal calibrations, if needed. The reflector can use this time to ramp up its transmitted signal (if necessary) in advance of the transmission of the CS SYNC packet. The duration of T_IP1 is shown in Table 3. After T_IP1, the reflector device transmits its CS SYNC packet. The CS step mode 1 may have a payload as part of the CS SYNC packet. The reflector may transmit its CS SYNC packet even if it does not receive a previous CS SYNC packet from the initiator or if the CS SYNC packet was received with bit errors.

Parent topic: The channel sounding steps description

CS step mode 2

CS mode 2 is used to measure the phase rotations of the RF signal between the initiator and the reflector. The theoretical description of this mode is in RTP estimation fundamentals. The devices supporting this feature should fully support CS step mode 2. The structure of CS step mode 2 is shown in Figure 10.

CS step mode 2 tone exchange

Before each CS step, a frequency hop is created. The duration of the frequency hop is marked as T_FC. The initiator starts the transmission with an Unmodulated Carrier (UC) RF signal. The duration of the unmodulated carrier RF signal should be T_PM*N_AP, where T_PM is the phase-measurement period and N_AP is the number of antenna paths. Each individual T_PM reserves the first configurable time (1, 2, 4, 10 us) for antenna switching. The available values of T_PM are given by the standard and shown in Table 4.

Table 4. Permitted values for T_PM

T_PM Index	T_PM	Comment
1	10 us	Optional
2	20 us	Mandatory if any shorter T_PM extent is supported, else optional
3	40 us	Mandatory

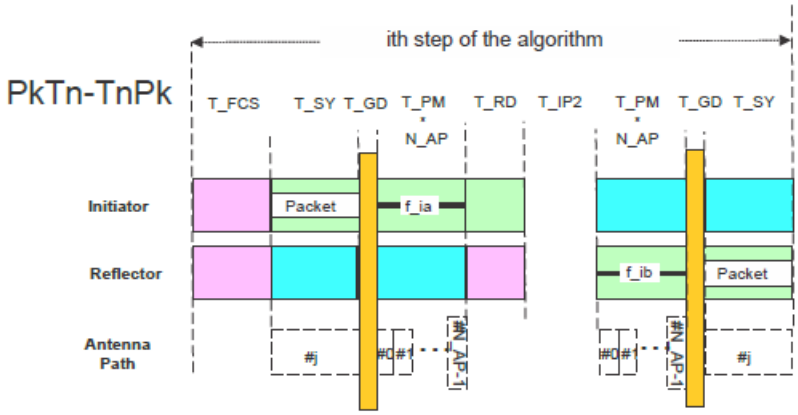
For added security, each N_AP set of T_PM length transmissions shall be followed by a single tone-extension slot of the same T_PM extent. This tone-extension slot may or may not carry a transmission. The presence of the added security is controlled by random bit generation.

After the transmission from the initiator completes, a defined ramp-down window of 5 us is allowed for the initiator to remove the transmitted energy from the RF channel. The same rule is applied here. The output power shall be lower by 40 dB than the output power used during the transmission of the UC RF signal. The signal level is measured at the initiator's antenna. T_IP2 represents the idle time between the transmission including the tone extension slot from the initiator and the transmission from the reflector. Devices may use this time for internal calibrations (if needed). The reflector can use this time to ramp up its transmitted signal (if necessary) in advance of the transmission of the UC. The permitted values for T_IP2 are shown in Table 5. The T_IP1 value can be different from T_IP2.

Table 5. Permitted values for T_IP2

T_IP2 Index	T_IP2	Description
1	10 us	Optional
2	20 us	Optional
3	30 us	Optional
4	40 us	Mandatory if any shorter T_PM extent is supported, else optional
5	50 us	Optional
6	60 us	Optional
7	80 us	Mandatory if any shorter T_PM extent is supported, else optional
8	145 us	Mandatory

After T_IP2, the reflector device transmits its (UC) RF signal. The duration of the unmodulated carrier RF signal should be T_PM*N_AP, where T_PM is the phase-measurement period and N_AP is the number of antenna paths. Each individual T_PM reserves the first 2 us for antenna switching. The N_AP parameter is common to the entire CS procedure and shall range from 1 to 4. An



added extension transmission slot shall immediately follow the last valid N_AP transmission, as it was similarly present in the initiator-to-reflector direction. If a transmission is present, it shall be identical to that of the last T_PM slot and it shall use the same antenna element used in that slot. If a transmission is not present in the tone-extension slot, then that T_PM period shall still be present but not carry a transmission. The presence of the added security is controlled by the random bit generation.

Parent topic: The channel sounding steps description

CS step mode 3

CS step mode 3 is used to measure the phase rotations of the RF signal and the round-trip time between the initiator and the reflector. It uses a combination of the previous modes. All the devices supporting the CS feature may optionally implement also step mode 3. Figure 11 is defined for CS step mode 3.

CS step mode 3 packet exchange

A frequency hop is created before each CS step. The channel hop duration is marked as T_FCS. In the reflector to initiator direction, the duration is given by the CS SYNC synchronization packet (T_SY), transition time between the packet mode to tone (T_GD), and the unmodulated carrier RF signal T_PM*N_AP. T_PM is the phase-measurement period and N_AP is the number of antenna paths. Each individual T_PM reserves the first configurable time (1, 2, 4, 10 us) for the antenna switching (T_SW).

If a tone-extension slot is present, then the tone duration is (T_SW+T_PM)x(N_AP+1). If the tone-extension slot is not present, then the tone duration is (T_SW+T_PM) x N_AP. To compensate for the missing tone slot a “no tone” slot is added after the synchronization.

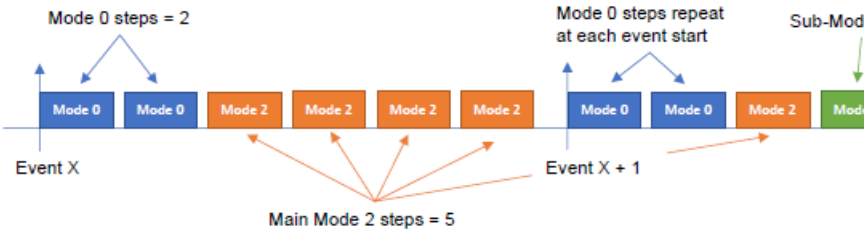
The initiator starts a transmission with the Unmodulated Carrier (UC) RF signal. The duration of the unmodulated carrier RF signal should be T_PM*(N_AP + 1) and it should also depend on the physical layer used. CS step mode 3 may use a payload as part of the synchronization.

For added security, each N_AP set of T_PM length transmissions shall be followed by a single tone-extension slot of the same T_PM extent. This tone-extension slot may or may not carry a transmission. If a transmission is present, it shall be identical to that of the last T_PM slot and it shall use the same antenna element used in that slot. If a transmission is not present in the tone-extension slot, then that T_PM period shall still be present, but it shall not carry a transmission. The presence of a physical transmission in the extension transmission slot is seeded by the random bit generation.

After the transmission from the initiator is completed, a defined ramp down window of 5 us (T_RD) is allowed for the initiator to remove the transmitted energy from the RF channel. After T_RD, the output power should be lower by 40 dB than the output power during the transmission of the synchronization. This is measured at the initiator’s antenna.

T_IP2 represents the idle time between the transmission from the initiator and the reflector. Devices may use this time for internal calibrations (if needed). The reflector can use this time

to ramp up its transmitted signal before the transmission. The duration of T_IP2 is defined the same way as the CS step mode 2 in Table 5.



After T_IP2, the reflector device transmits a CS synchronization using the unmodulated carrier. The duration of the unmodulated carrier shall be either T_PMxN_AP or T_PMx(N_AP + 1). This depends on whether a transmission is selected for the tone extension slot. If a transmission is present, it should be identical to that of the last T_PM slot and it shall use the same antenna element as in that slot. If a transmission is not present in the tone-extension slot, then the T_PM period should not be present. The presence of a physical transmission in the extension is controlled by the random bit generation.

The reflector device may then transmit its CS synchronization even if it does not receive a CS synchronization from the initiator or if the synchronization was received with bit errors.

Parent topic: The channel sounding steps description

Channel Sounding mode sequencing

The CS mode sequencing describes specific time slots of the whole flow. The CS event will always start with one or more mode 0 steps, which is represented by blue rectangles in FFigure 12. A series of subsequent non-mode 0 steps shall follow in the same event. Any CS procedure shall only use at most two non-mode 0 modes. One of these two is known as the main mode and the other is known as the submode. An example of this sequencing is shown in Figure 12. Many other CS mode sequencing examples can be generated.

Channel Sounding mode sequencing

The submode insertion sequences the occurrence of the main mode steps and the submode steps and uses the following parameters:

- Main_Mode_Min_Steps – the minimum main-mode steps that shall occur before a single submode step.
- Main_Mode_Max_Steps – the maximum main-mode steps that shall occur before a single submode step.

The number of main-mode steps that occur before a submode step shall be between Main_Mode_Min_Steps and Main_Mode_Max_Steps, inclusive. The exact number of main-mode steps that occur before a submode step insertion is randomized for each sequence. The randomized function is defined by the BLE standard.

Parent topic:*The channel sounding standard description*

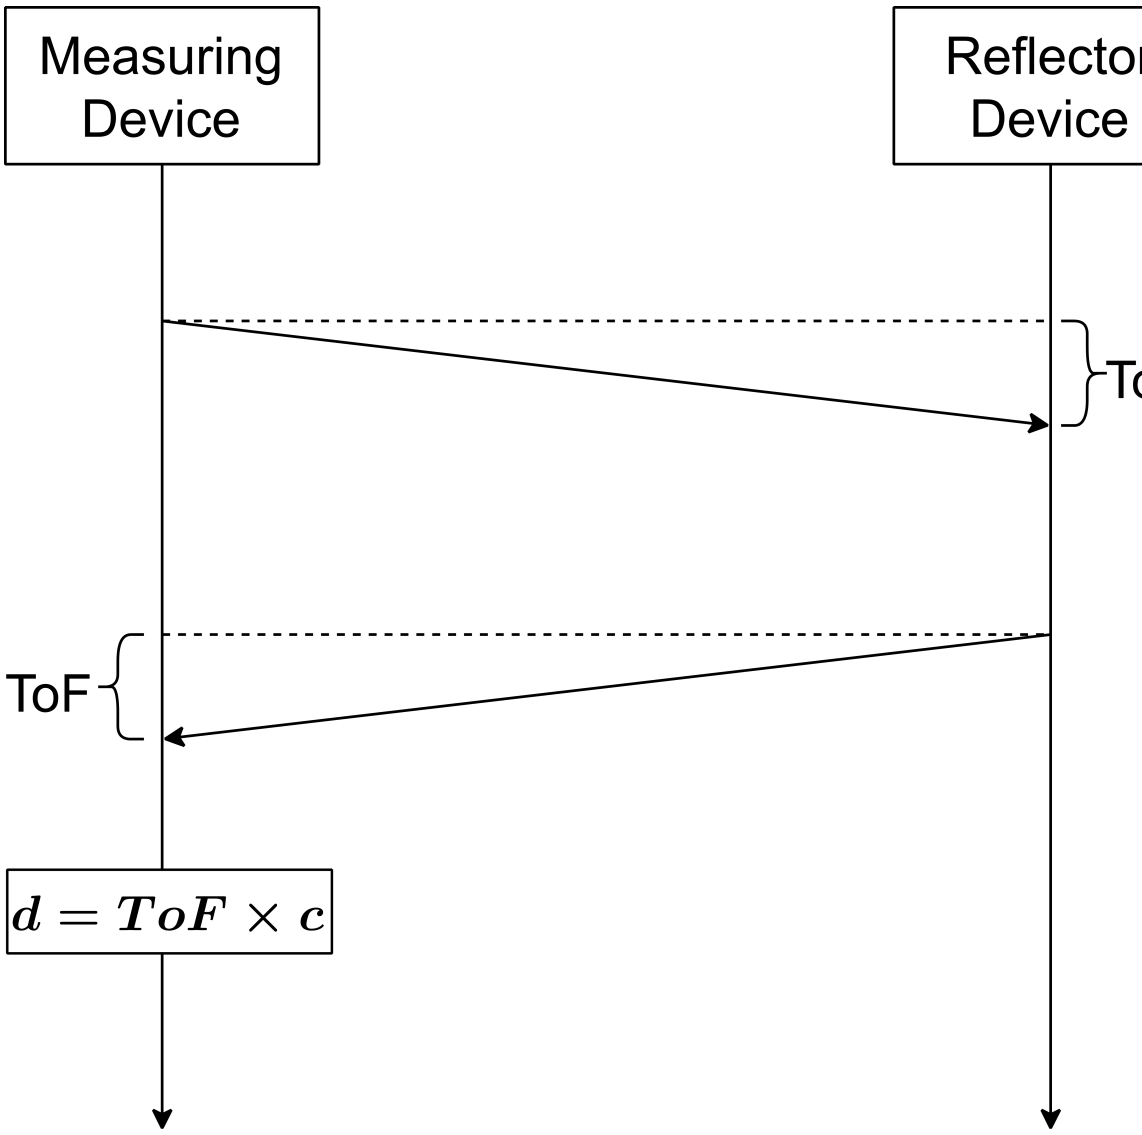
Wireless channels randomization

The whole ISM frequency band is used for the CS technique for distance estimation. There is an important aspect about the frequency channel switching. The ISM band is not swept linearly, but there is a procedure to create randomly selected channels. The BLE standard assumes the use of the channel-selection algorithm for two cases:

- Channel-selection algorithm for mode 0 steps
- Channel-selection algorithm for non-mode 0 steps

The channel-selection algorithm #3a is used to generate a randomized channel map with uniform distribution for mode 0 CS steps. The number of times that the mode 0 channel list is required to be regenerated in a CS procedure depends on several factors, including the size of the list of included filtered channels, as indicated by the filter-channel bitmap Chesterfield (the number of non-mode 0 steps included in a CS event and a CS procedure along with the runtime construction of CS events whose content may vary from event to event), depending on the CS mode sequencing.

The channel-selection algorithms #3b and #3c support channel selection for each non-mode 0 CS step within a CS procedure. Only one of the two algorithms shall be used within a single CS procedure. The number of times that the non-mode 0 channel list is required to be regenerated in a CS procedure depends on several factors, including the size of the list of included filtered channels, as indicated by the filter channel bitmap CSFilteredChM, the number of times the filtered channel map is repeated in a procedure for non-Mode 0 steps, along with the runtime construction of CS events whose content may vary from event to event (depending on the CS mode sequencing).



Detailed information about the wireless channels' randomization algorithms is in the BLE standard.

Parent topic:*The channel sounding standard description*

RTT estimation fundamentals

The round-trip time (previously known as the time of flight) is a method to measuring the distance between a sensor and an object, based on a precise measurement of the time difference between the transmission of a signal by the sensor and its return to the sensor after being reflected by an object. This approach is part of the RTT measurement. Wireless ToF applies the same concept to two wireless devices that can perform distance measurement between them by exchanging packets and accounting for radio latencies and turn-around time overheads.

The narrowband ToF requires at least two devices with NBW radio support to exchange packets over the air. As shown in Figure 13, it is based on a record of times at which the initial packet was transmitted by the MD and the time at which a response packet is received from the RD by the MD. The MD can calculate a ToF of the packet exchange. Using the calculated ToF, a distance estimate (or range) between the two devices can be computed. The determined distance (d) can be employed for a variety of functions, such as taking a specified action when the distance is above or below a threshold.

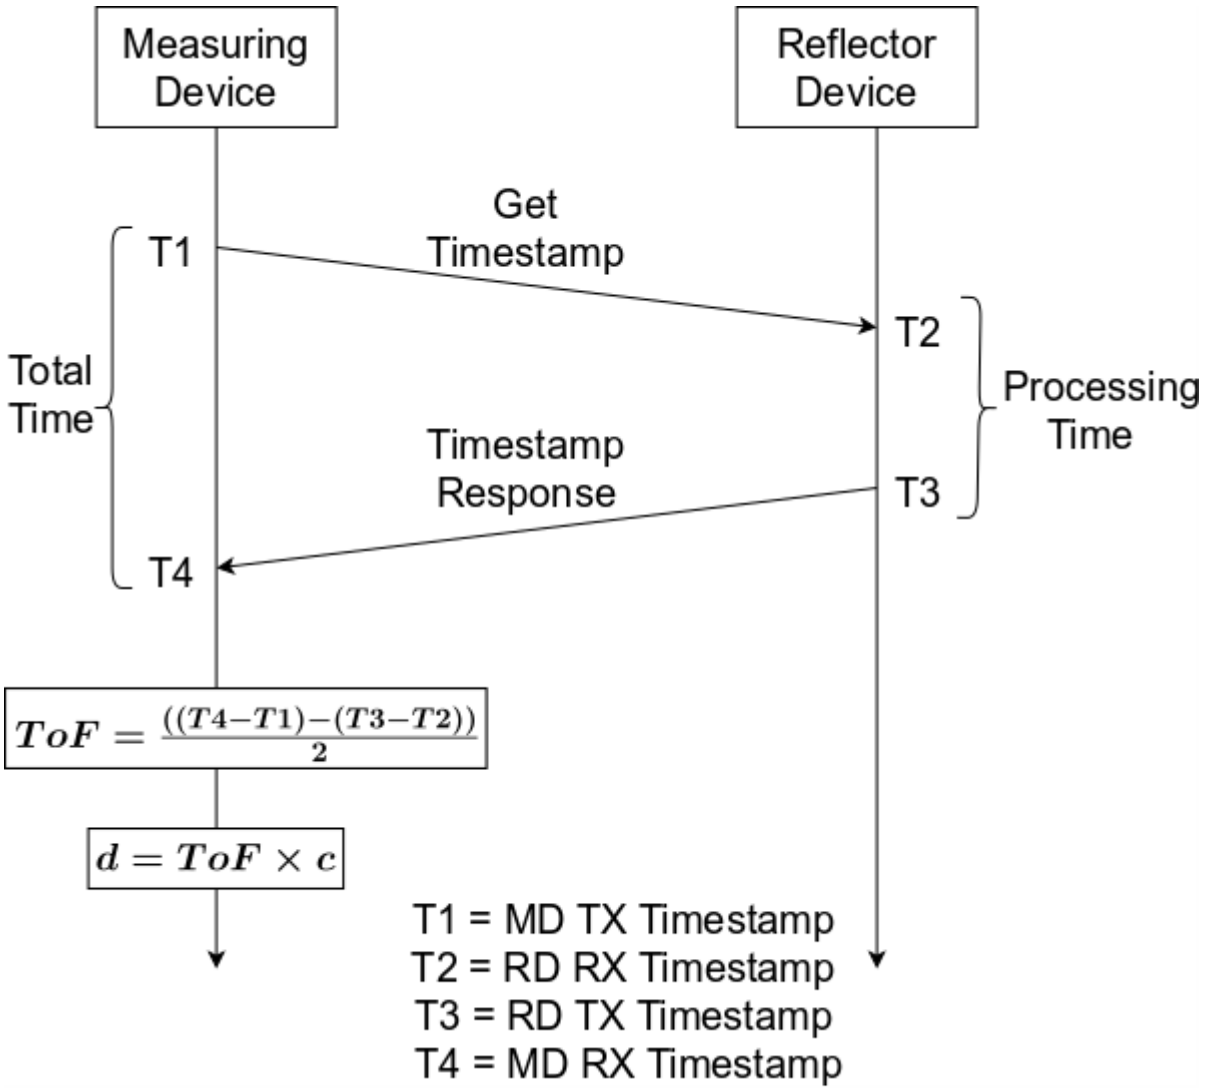
Basic ToF sequence

As shown in Figure 13, a method to capture the timestamps at which the packets are transmitted and received is required at both ends. Furthermore, these timestamps must be shared from RD to MD for the ToF calculation. The MD records a count from a timer (designated T1) in response to initiating transmission of the ranging packet. In response to receiving the ranging packet, the RD records a count from a local timer (designated T2). The RD takes a certain amount of time to process the incoming packet and send a response packet. This time is designated as "Processing Time", which is an overhead that must be eliminated to get an accurate ToF reading. In response to initiating the transmission of the response packet, the RD stores the count (designated T3). The response packet includes a data payload indicating the timestamps to calculate the RD processing time. Upon receiving the response packet, the MD records the count (designated T4). With these timestamps, a ToF value can be generated according to Equation 1..

Calculation of ToF

$$ToF = \frac{(T4 - T1) - (T3 - T2)}{2}$$

Once the ToF value is calculated, the distance can be estimated using Equation 2..



Distance estimation using ToF

$$Distance_m = ToF \times c$$

Figure 14 shows the sequence of packet exchange and timestamp collection for a single measure-

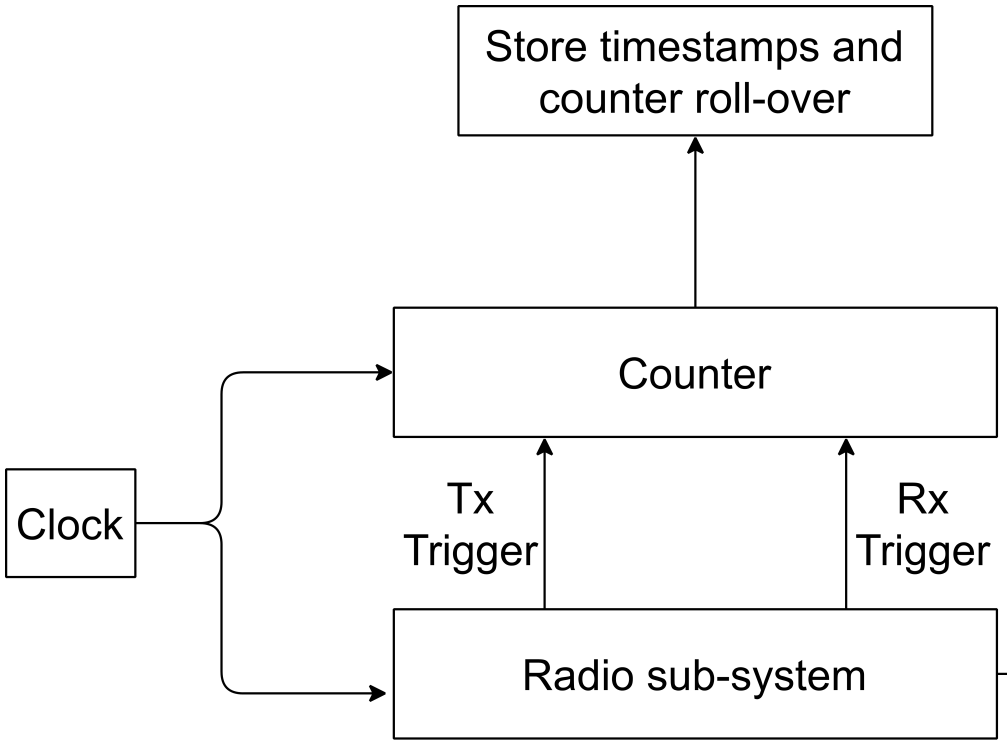
ment.

ToF calculation using timestamps

Narrowband ToF

Radio frequency waves travel at the speed of the light (c), which is a known constant (c 3×108m/s); 1 m is equivalent to ~3.3 ns. A system measuring the ToF would ideally require a high-speed clock (GHz) to generate the timestamps with 1-ns accuracy, which is not possible with today's low-cost deep submicron technologies. For mass-market applications, where low power consumption, low system complexity, and a tight cost budget are a constraint, a low-cost MCU with an integrated 2.4-GHz radio can be used. Typically, these devices work with a high-accuracy reference clock (Fref). As an example, using a reference clock of 32 MHz provides raw ToF accuracy of about 10 m, which may be adequate to validate a more precise but spoofable distance measurement. However, 10 m is too coarse and might not be useful as most applications require accuracy that is much finer. A typical target is to have accuracy of less than 1–2 m. To achieve such accuracy, a number of ToF measurements may be taken (approximating a normal distribution) and averaged. When using ToF distance estimation, there is a trade-off between accuracy and measurement time.

A narrowband ToF measurement systems consists of the following:



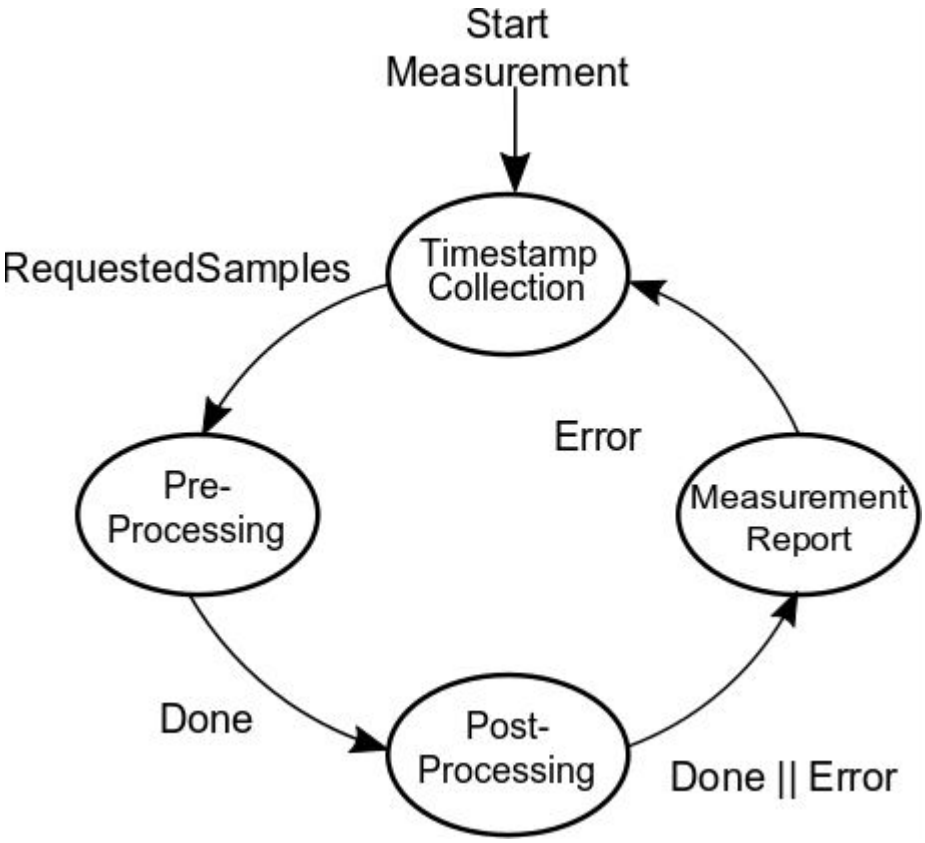
1. Counter for timestamping that is synchronized to the radio subsystem clock reference (Fref)
2. Precise hardware-based timestamping mechanism

3. Measurement protocol that includes the following steps:
    - Timestamp collection
    - Preprocessing
    - Postprocessing
    - Measurement report

Timestamping mechanism

A precise timestamping mechanism is required on both ends for the NBW ToF to achieve the targeted accuracy. At the system level, this not only imposes requirements on the stability and relative accuracy of the timestamping clocks used by both MD and RD, it is also desired that the timestamp-capture mechanism does not contribute to additional jitter. This requirement typically implies that timestamping must be hardware-based and utilize precise triggers for both packet transmission and reception.

To generate precise timestamps, a deterministic and accurate counter is required. For instance, a 16-bit MCU timer, clocked by the radio's reference clock, can be chosen. Given the counter-clock frequency and its size, the count overflows and roll-overs happen every few milliseconds, which must be accounted for as well. The timestamp trigger should be generated from the radio SoC to ensure a stable trigger at specific anchors of the packets. For instance, the transmission timestamp source could be taken from a signal asserted when the system is ready to transmit the first preamble bit. On the receiving end, a packet-reception trigger source can happen when the radio detects the synchronization delimiter (such as the access address in Bluetooth LE or Start-of-Frame Delimiter (SFD) for IEEE 802.15.4) arrival for the packet. Figure 15 shows the timestamp block diagram.



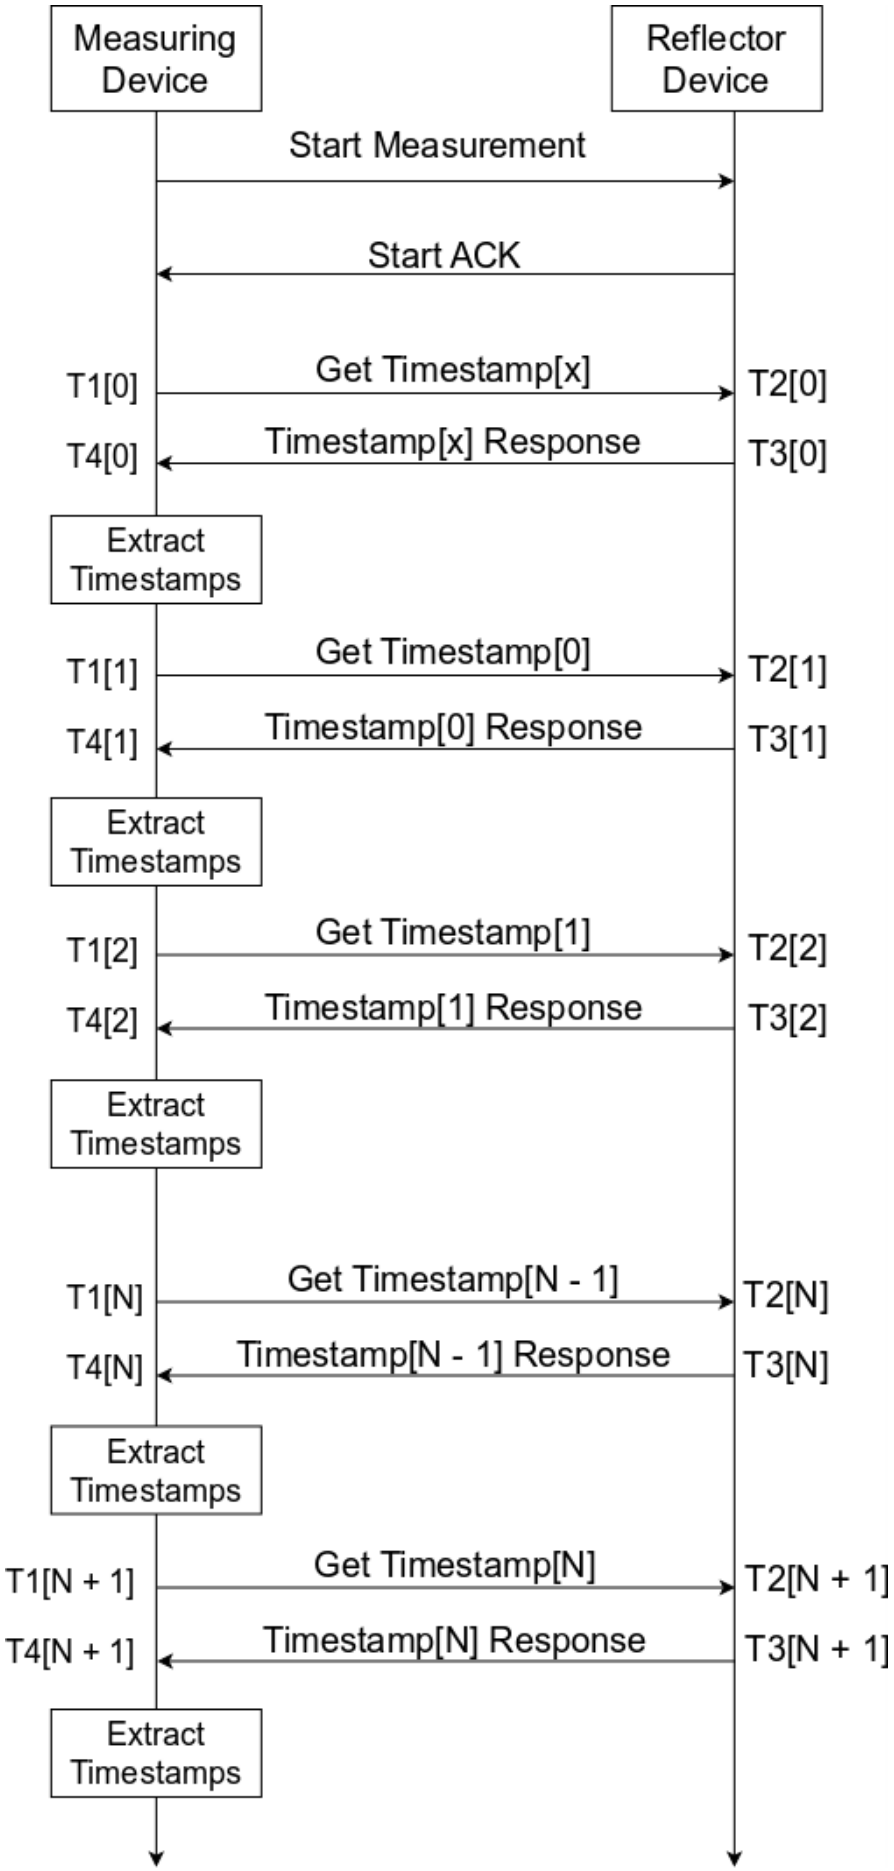
Timestamp block diagram

Parent topic: Narrowband ToF

Multi-stage ToF

The ToF measurement consists of four stages: timestamp collection, preprocessing, postprocessing, and measurement report

ToF stages



Timestamp collection

During this stage, the devices perform a series of packet exchanges. Each exchange creates a set of timestamps T1 – T4, which are made available to the MD for analysis. As T2 and T3 are generated at RD, they shall be shared on the response packet along with other information that might be useful, such as RSSI. As T3 (RD TX Timestamp) is generated by a transmission of the response packet, a causal implementation is possible by having the RD response to the MD contain timestamps corresponding to the previous packet exchange, as shown in Figure 17.

Wireless communication, especially in the shared Industrial, Scientific, and Medical (ISM) frequency band can be hampered by interference due to proximity of other radios utilizing the same frequency band and/or multi-path propagation artifacts. Using multiple carrier frequencies for ToF can reduce the impact of such artifacts and increases the likelihood of a successful ToF measurement. As explained in this document, a ToF distance measurement typically comprises of exchanging a set of packets for physical ToF measurements (by timestamping) as well as control communication between the two wireless nodes. Due to interference and artifacts, any of the packets containing either the timestamp requests, timestamped measurements, or measurement command packets might fail to arrive in either direction. For robust operation, a ToF measurement system should incorporate a robust mechanism that can recover from such events. Such a mechanism must be intelligent enough to identify and skip specific carrier frequencies if they have persistent interference and continue with the measurement on a different frequency, rather than just abort due to the missed packets.

Parent topic: Narrowband ToF

Preprocessing

With the timestamps already generated and stored at MD, the pre-processing stage calculates a ToF estimate for every T1 – T4 sample set. Such calculations can be performed using integer math. However, to improve the measurement accuracy, fixed-point or floating-point math can be used. To calculate each ToF estimate, the system performs the following steps:

1. Calculate the process time in function of timer counts. Any timer overflow must be accounted in Equation 3.

Equation 3. Process time calculation

$$ProcessTime = T3 - T2$$

2. Calculate the total time in function of timer counts. Any timer overflow must be accounted in Equation 4.

Equation 4. Total time calculation

$$TotalTime = T4 - T1$$

3. Translate the process time from TimerClockFrequencyHz counts to seconds, as shown in Equation 5.

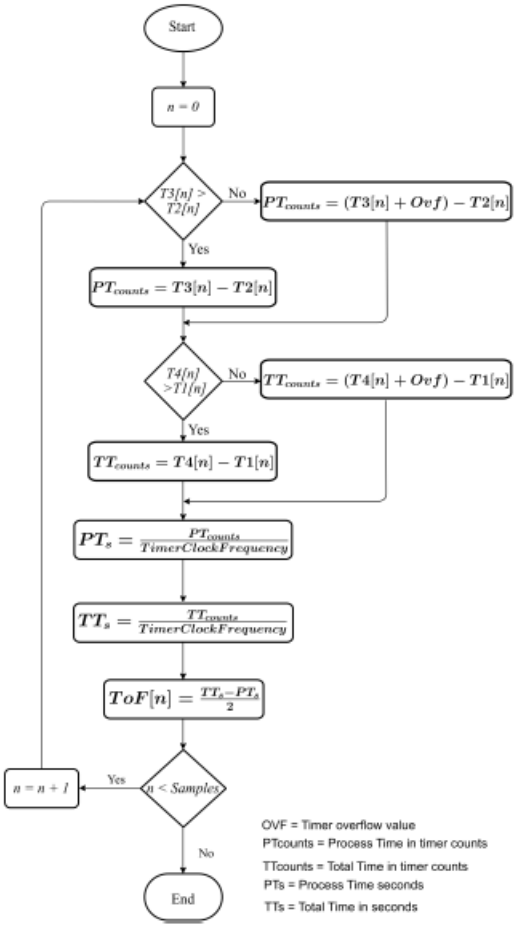
Equation 5. Process time to seconds

$$ProcessTime_s = \frac{ProcessTime}{TimerClockFrequencyHz}$$

4. Translate the total time from TimerClockFrequencyHz counts to seconds, as shown in Equation 6.

Equation 6. Total time to seconds

$$TotalTime_s = \frac{TotalTime}{TimerClockFrequencyHz}$$



5. Calculate the ToF per sample, as shown in Equation 7.

Equation 7. ToF in seconds

$$ToF = \frac{TotalTime_s - ProcessTime_s}{2}$$

Figure 18 shows the previously discussed steps for n samples.

Individual ToF measurement and preprocessing flowchart

For a radio, it is typical to exercise the receiver's Automatic Gain Control (AGC) dynamic range to operate over the entire link budget or in response to the presence of interference. The AGC operation typically ensures that a certain level of down-converted signal is maintained at the receiver's Analog-to-Digital Conversion (ADC) over the receiver's entire dynamic range, until the receiver gain hits either a minimum or a maximum. Since the measurement resolution targeted in the ranging-distance estimates is in nano-seconds, any propagation time variability within the radio's analog front end due to gain adaptation must be carefully treated as a potential source of error, while performing the ToF distance estimation. This can be avoided by either performing a gain vs time propagation variability calibration. This can be addressed by choosing a robust method to choose an optimal AGC setting for a ToF measurement.

Parent topic: ToF Multistage

Postprocessing

The postprocessing step is typically applied over a set of individual ToF measurements with a goal to choose a reliable distance estimate from several single-shot measurements that may be individually lacking both accuracy and resolution. Statistical estimation techniques must be applied in this step to the collected data set. As an example, the postprocessing step can include data-processing techniques, calculation of a statistical average (ToFaverage, mean or median), weighted averages, and so on. It may include statistical tests for outlier rejection (among others) to improve ToF accuracy.

To cancel systematic delays in a ToF measurement, one option is to perform a calibration to estimate the bias that must be subtracted from ToFaverage. Such bias method can be carried out at a fixed distance between the two nodes. ToF is given as Equation 8.

Equation 8. ToF after bias

$$ToF_{final} = ToF_{average} - ToF_{bias}$$

When a ToFfinal value is calculated, the distance between the two wireless nodes may be estimated by dividing ToFfinal by the ideal ToF value expected for a reference distance of 1 m (Equation 9).

Equation 9. Distance estimation

$$Distance_m = \frac{ToF_{final}}{3.33ns}$$

The measurement report is created when the calculated distance estimate is ready. The measuring device reports the estimated distance and an indication that the measurement is complete.

Parent topic: ToF Multistage

Zero distance calibration (ToFbias)

The ToF calculation must account for any systematic offsets in the calculation, which may be contributed by the specific choice of receive and transmit trigger anchors in the exchanged packets, as well as radio-specific implementation, such as data path latencies, delays, and so on. This systematic offset in ToF computations may be eliminated via characterization or calibration.

For both the transmitted and received packets, the location of the anchor points in the packet that are timestamped are known. Combining this knowledge of anchor triggers to the ToF packet format and communication data rate, the theoretical time delay between a packet transmission by a device and its reception by another device for a known reference distance could be precisely computed if the data path latencies in the transceiver chain were negligible or precisely known. For ToF distance estimation, the timing resolution that must be resolved is in nanoseconds. This requires a reference physical measurement to have a precise measurement of the Radio Frequency (RF), analog and digital data path latencies, as well as other implementation delays in the control path.

For this purpose, a calibration method is implemented by placing both devices (MD and RD) at a known distance and perform average ToF measurements over a set of exchanged packets. This enables the computation of averaged ToFbias, which is calculated according to Equation 10.

Equation 10. ToF bias

$$ToF_{bias} = ToF_{calibration} - (CalibrationDistance*3.33)$$

The ToF measurement is also impacted by propagation delay variation in the RF/analog front end of the radio as a function of the Automatic Gain Control (AGC) step in use. It is recommended to perform the ToF zero-distance calibration at a known distance and gain the configuration of the radio. For a random distance measurement using ToF, the knowledge of the receiver's gain during the measurement and its relationship to the gain value used during the zero distance calibration may be used to compensate for the subsequent ToF measurements.

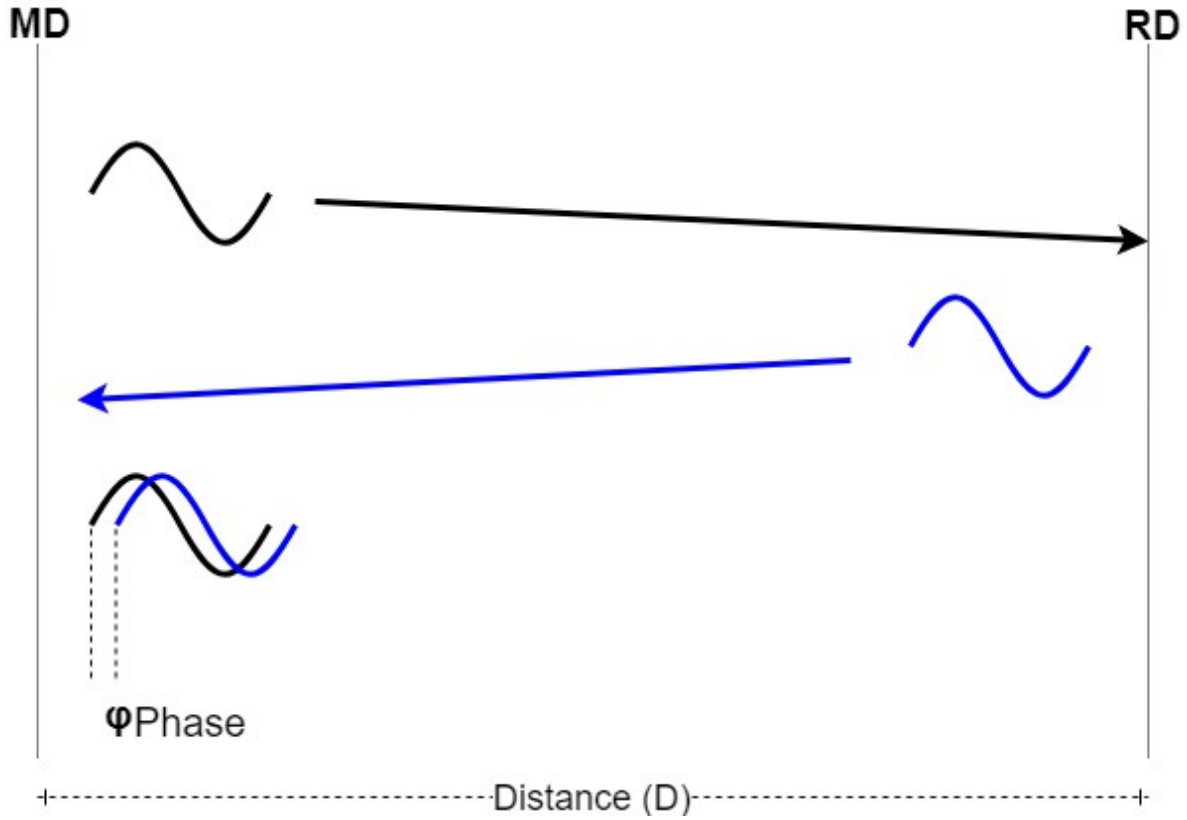
Parent topic: Narrowband ToF



Parent topic:*RTT estimation fundamentals*

RTP estimation fundamentals

The round-trip phase (previously known as PDE) is a technique that utilizes the phase difference between an MD (which is the initiator) and determines the need to estimate distance and an active RD to determine the distance between them.

In its simplest form, the MD transmits a continuous wave to the RD, which synchronizes its phase and sends the signal back to the MD. The MD then compares the phase of the received signal with the phase of the signal it transmitted, obtaining a phase difference.

Phase difference using an MD and an RD

With this information, the distance can be measured using the following equation:

Equation 11. Measure distance using a single-phase difference

$$d = \frac{c}{2f} \cdot \left(\frac{\varphi}{2\pi} + n \right)$$

Where:

- φ is the phase difference, as measured by MD.
- c is the speed of light.
- f is the carrier frequency.
- n is the number of wraps.

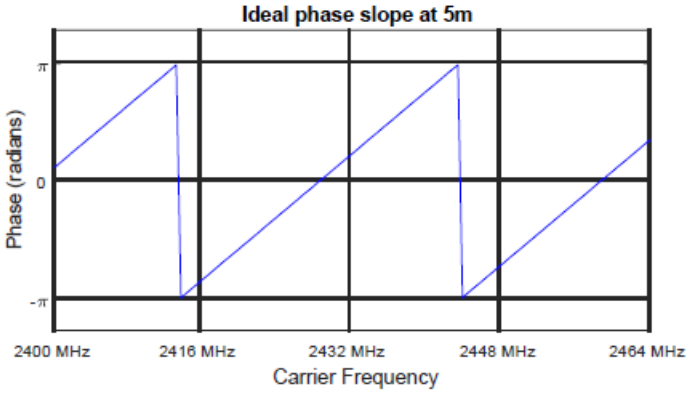
Note that the number of wraps (n) depends on the wavelength of the carrier frequency.

Equation 12. Wavelength of the carrier frequency

$$\lambda = \frac{c}{f}$$

If the distance to measure is larger than λ, the phase wraps (creating a distance ambiguity) and the number of wraps (n) must be accounted for.

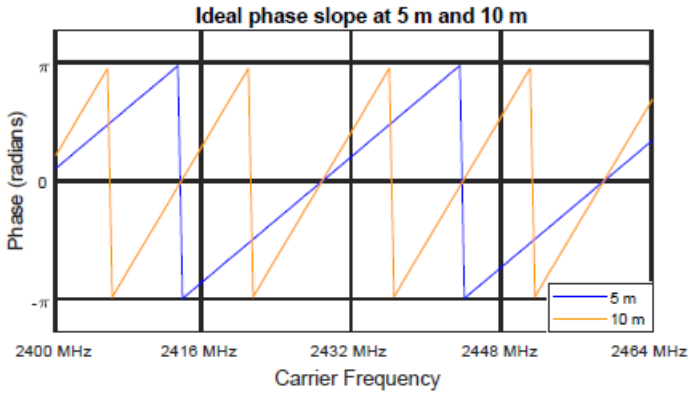
A sweep of multiple frequencies is used to reduce the above-mentioned ambiguity and to aid in analyzing multipath scenarios. If the phase difference is obtained at two different frequencies and the equations are combined, the following equation can be used to determine the distance:



Equation 13. Distance estimation using two frequencies

$$d = \frac{c}{4\pi} \cdot \frac{\varphi_2 - \varphi_1}{f_2 - f_1}$$

Slope-based PDE



If a frequency sweep is done at a fixed distance and with constant spacing between the frequencies (Δf), the phases obtained at each frequency in the sweep produce a slope.

Phase slope at 5 m

There is a linear relationship between the phase slope observed and the distance to the object. The smaller the slope, the shorter the distance between RD and MD.

Phase slope difference at 5 m and 10 m

Using this slope, the equivalent distance can be obtained using the following equation:

Equation 14. Distance obtained from phase slope

$$d = \frac{c}{4\pi} \cdot slope$$

To get the slope-based distance using phase differences obtained at several frequencies, Equation 13 must be applied multiple times, as shown in the following equation:

Equation 15. Immediate distance from a single-phase difference

$$d_n = \frac{c}{4\pi} \cdot \left(\frac{\varphi_n - \varphi_{n-1}}{f_n - f_{n-1}} \right)$$

The final distance estimate can be obtained as follows:

Equation 16. Distance obtained from the average of immediate distances

$$d_{slope} = \frac{1}{n-1} \sum_{k=1}^{n-1} d_k$$

The maximum measurable distance depends on the spacing between the measurement frequencies (Δf) and it is given by the following equation:

Equation 17. Maximum distance measurable using the slope method

$$d_{max} = \frac{c}{4} \cdot \left(\frac{1}{\Delta f} \right)$$

Parent topic:*RTT estimation fundamentals*

Complex Distance Estimation (CDE)

In CDE, the phase measurements taken at each frequency are converted into a complex signal in the frequency domain. By transforming it to the time domain using the Inverse Fast Fourier Transform (IFFT), we obtain the distribution of the propagation delays that are in the signal.

The maximum propagation delay that can be measured without ambiguity is determined by the spacing between the measurement frequencies (Δf) and it is given by the following equation:

Equation 18. Largest unambiguous propagation delay measurable using the CDE method

$$t_{max} = \frac{1}{2 \cdot \Delta f}$$

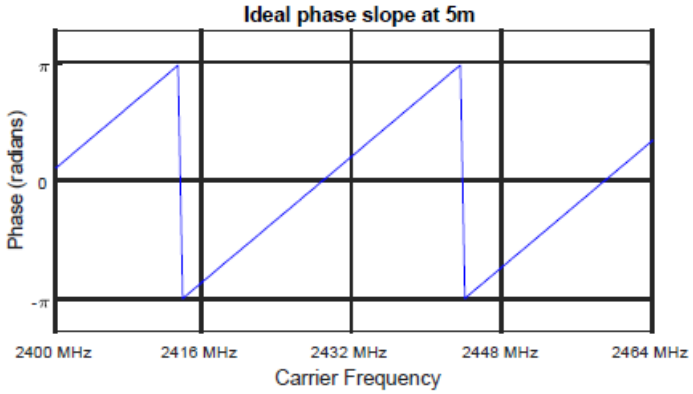
The maximum measurable distance can be obtained by multiplying the maximum propagation speed by the speed of light (c):

Equation 19. Maximum distance measurable using the CDE method

$$d_{max} = t_{max} \cdot c$$

The distance estimate is obtained using the following equation:

Equation 20. CDE distance calculation

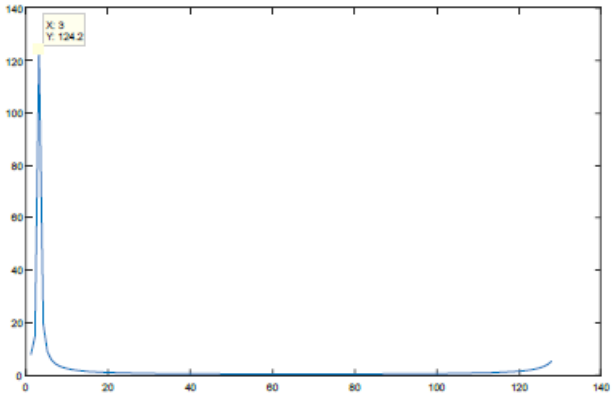


$$d_{cde} = d_{max} \cdot \frac{n_{peak} - 1}{M}$$

Where npeakis the bin with the highest peak, M is the number of bins used in the IFFT, and dmax is the largest unambiguous distance. Let's assume an ideal phase difference response for two boards separated by 5 m. The phase difference is measured using Δf = 500 kHz. The maximum measurable distance is given by the following equation:

Equation 21. Maximum distance measurable using Δf = 500 kHz

$$d_{max} = \frac{c}{2 \cdot \Delta f} = \frac{299792458 \frac{m}{s}}{2 \cdot 500000_{Hz}} = 299.7925_{m}$$



The wrapped phase response obtained from the frequency sweep at the same distance (see Figure 20) is shown in Figure 22.

Ideal phase slope at 5 m using Δf = 500 kHz

If a 128-bin FFT is applied to an array containing the wrapped phase points in their rectangular form, the output is shown in Figure 23.

Ideal 128-bin IFFT for the 5-m slope

The bin holding the biggest peak is number 3. Use the following equation to obtain the estimated distance:

Distance calculation for bin 3 using 128-bin FFTe

$$d_{cde} = 299.7925_m \cdot \frac{3-1}{128} = 4.6842_m$$

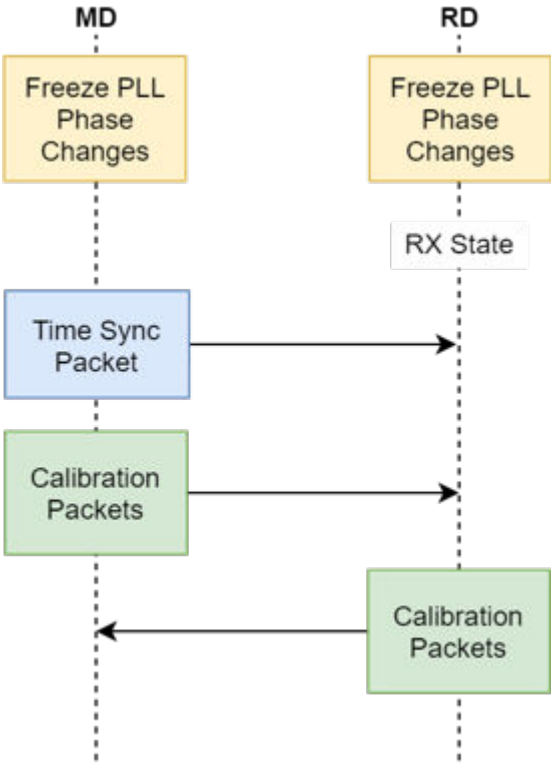
The resolution of the measured distance depends on the frequency step selected and the number of bins used in the IFFT.

Parent topic:*RTP estimation fundamentals*

PDE implementation

A two-way PDE estimation algorithm typically requires precise acquisition of phase changes across a span of frequencies by each participating device. The phases are derived from the captured I and Q samples in the receiver of a device for a tone transmitted by the peer device with a known raster.

The PDE implementation mainly consists of four steps: initialization and calibration, IQ data capture, phase processing, and distance estimation.



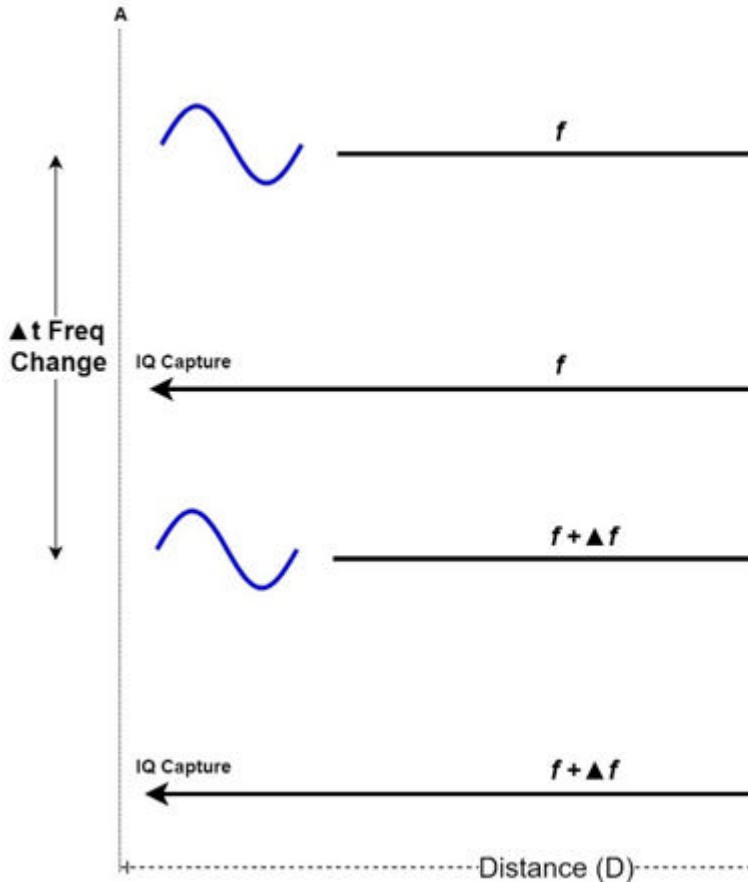
Initialization and calibration

Before capturing the IQ samples, four important conditions must be met:

1. All transceiver impairments that can impact the phase capture information (DC offsets, IQ mismatch, filtering transfer function contributions, PLL phase excursions, and so on) must be minimized.
2. Theoretically, the IQ signal amplitude does not affect the phase calculations. However, signal saturation or fading can affect the accuracy of phase calculations. Ensure a good dynamic range for the captured IQ samples.
3. The measurement of phase differences implies that changes in phase are only produced by the distance between the test devices. The PLLs in both devices must remain frequency-coherent throughout the capture process.
4. Some algorithms require changing the tone frequencies with a specific time interval. The devices must synchronize their transmit and receive cycles accordingly.

The initialization and calibration stages ensure that all of the above conditions are met before capturing the IQ samples.

Initialization and calibration sequence



Parent topic:PDE

IQ data capture

Two-way PDE algorithms use multiple phase differences obtained at several frequencies. To achieve this, the MD and RD must generate Continuous-Wave (CW) tones and capture IQ samples in all the measurement frequencies.

The base mechanism consists of device A, which generates a tone at frequency f. At the same time, the peer device B sets its radio to the RX mode at f and starts to capture IQ samples. After a fixed amount of time, devices A and B change roles. Now device B generates a tone in f and device A starts the RX and IQ capture at f. This is a tone exchange sequence.

After the tone exchange sequence ends, both devices return to their original roles, but the frequency is updated by Δf. For this new tone exchange, device A generates a tone at f + Δf. Device B also sets its radio to the RX mode at f + Δf and captures IQ samples. The tone exchange sequence is repeated for all frequency values that are defined for this measurement

Multiple frequency IQ samples capture sequence

Parent topic:PDE

Phase processing

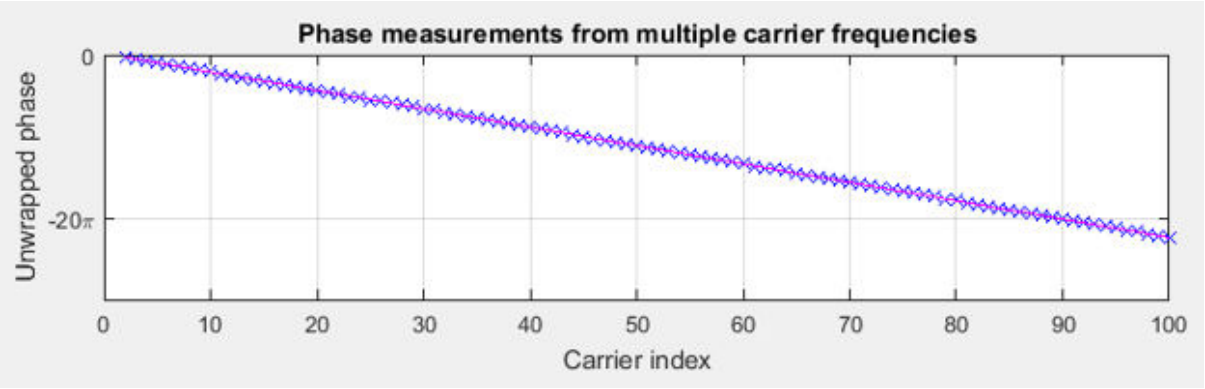
After the IQ samples are captured on each device, the phase difference is obtained using the following equation:

Equation 22. Phase from IQ samples

$$\varphi = arctan2\left(\frac{Q}{I}\right)$$

Each device holds the phase difference slope of the peer device against its own local oscillator. To obtain the phase combination result of the distance, the phase slope from the RD must be added to the phase slope from the MD.

Equation 23. Phase vector combination



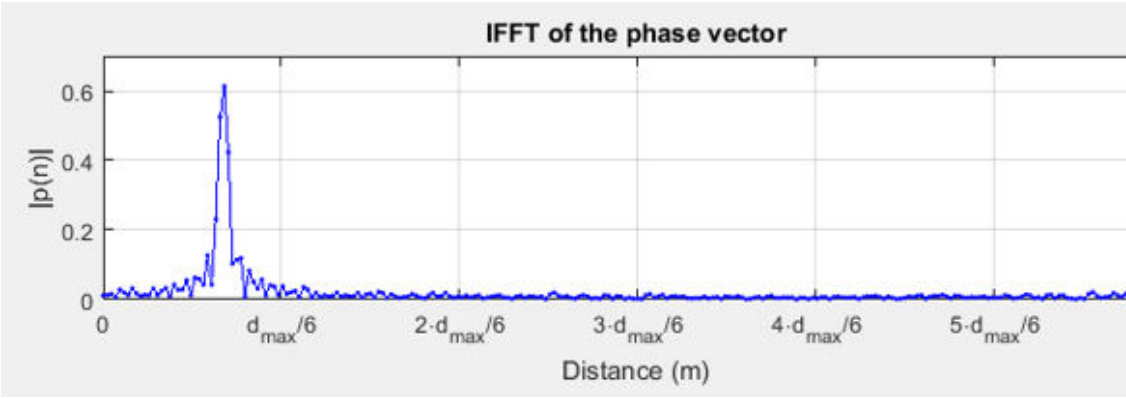
$$\Delta\varphi = \varphi_{MD} + \varphi_{RD}$$

This phase slope can now be used to perform distance estimation. As shown in Figure 21, depending on the frequencies used and the measured distance, phase wraps may occur.

Figure 27 shows how the measured phase values change as a function of the carrier-frequency

index. The data for this example is obtained using a wired setup, where the two devices are connected by a cable. A total of 99 carriers are used with the first carrier (index 2) corresponding to a frequency of 2400.5 MHz. The last carrier (with index 100) corresponds to a frequency of 2449.5 MHz. The frequency step size is 500 kHz.

Phase measurements (unwrapped) across multiple carrier frequencies



Parent topic:PDE

Distance estimation

After the IQ samples are captured on each device, the phase difference is obtained using the following equation:

The phase vector obtained as a result of phase processing is the input for the distance-estimation algorithm. It can be used directly with Equation 16 for the slope method or as an IFFT input for the CDE method.

IFFT of phase vector

Figure 28 shows the IFFT magnitude response of the phase vector illustrated in Figure 27. The labels on the x-axis show the distance in meters. The final estimate is generally obtained from the peak location of the IFFT. The zero-meter compensation may be necessary to account for the delays within the radio front end.

Test setup description

The basic test setup description is based on information provided in the following complementary application notes:

- Channel Sounding Wireless Ranging Demo Application
- KW47 Wireless Ranging Performance Measurement. The individual test setup is not part of this document.

The Channel Sounding Wireless Ranging Demo Application document contains simple out-of-box test setup description with all the important settings. The KW47 Wireless Ranging Performance Measurement is a validation report which uses more complex HW test setup to achieve precise and statistically evaluated results.

Conclusion

This application note describes the channel sounding standard and shows the step modes for distance estimation. The theoretical background of the RTT (ToF) and RTP (PDE) methods are also described.

Acronyms

The following acronyms are used in this document.

Acro	Description
CS	Channel Sounding
PDE	Phase-based Distance Estimation
RTP	Round-Trip Phase
RTT	Rount-Trip Time
ToF	Time of Flight
MD	Measuring Device
RD	Reflector Device
EDL(	Early Detect Late Commit
SFD	Start-of-Frame Delimiter
T_FC	The RF circuitry locks to the measurement channel (f_i). Devices can also use this time for additional internal calibrations, if necessary. The initiator may start to ramp up its output signal toward the end of this step.
T_FM	Time for Frequency Measurement
T_SY	Time for Synchronization sequence (CS packet)
T_IP1	Interlude Period 1 - transition from TX to RX and the other way around when transmitting in mode 1 (Tn-Tn)
T_IP2	Interlude Period 2 - transition from TX to RX and the other way around when transmitting in mode 2 (Tn-Tn)
T_GI	Transition time between packet and tone
T_RD	Ramp-Down time for transmission
T_PM	Single-antenna Phase Measurement period
N_AP	Number of Antenna Paths
T_SW	Antenna-Switching period
AGC	Automatic Gain Control
ADC	Analog-to-Digital Conversion
CDE	Complex Distance Estimation
IFFT	Inverse Fast Fourier Transform

Bluetooth Low Energy CCC Digital Key with Channel Sounding Introduction

NXP hardware platforms support the Bluetooth Low Energy applications implementing the Car Connectivity Consortium (CCC) Digital Key with channel sounding (CS) functionality. This document provides an overview of the deployment and operation of these applications, which also support the Bluetooth LE Channel Sounding localization functionality. This document is also a user guide for the sample applications included in the SDK release package.

Audience

The document also provides an overview of the procedure and steps to deploy and operate the Bluetooth Low Energy applications (enabling CCC Digital Key with CS). The NXP hardware platforms supporting these applications are the KW47-EVK, KW47-LOC, KW43-LOC and FRDM-KW43 boards.

This document is a useful reference for firmware and system developers who create CCC Digital Key-enabled products. The document also provides a high-level description of CCC Digital Key application scenarios that can be deployed on NXP development boards.

CCC Digital Key technology overview

The Car Connectivity Consortium (CCC) is a cross-industry organization advancing global technologies for smartphone-to-car connectivity solutions. CCC has developed Digital Key, a new open standard to allow smart devices such as smartphones to act as a vehicle key. Digital Key lets drivers lock and unlock their cars using their phone. It also allows them to start the engine and share access to friends or valets, using their phones.

The Digital Key Release 3.0 specification enhances Digital Key Release 2.0 by adding passive, location-aware keyless access. This feature allows vehicle users to access and/or start their vehicle while leaving their mobile device in their bag or pocket. They do not need to pull their mobile devices out to access the car. Passive access is not only vastly more convenient and a better overall user experience, it also allows vehicles to offer new location-aware features.

To support these new features, the CCC has developed a specification based on Bluetooth Low Energy with Ultra-Wideband (UWB). The specification enables passive keyless access and allows secure and accurate positioning.

CCC Digital Key applications overview

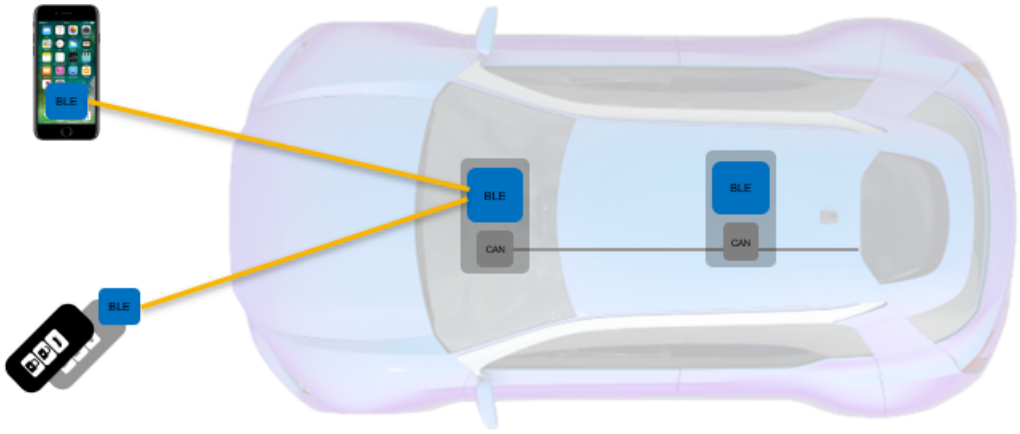
Note: The applications described below implement only the Bluetooth Low Energy functionality described by CCC Digital Key R3. They do not include any UWB or Secure Element functionality. The establishment of secure communication between the demos is simulated using dummy messages.

Digital Key Car Anchor application

The Digital Key Car Anchor demo application implements one of the multiple Bluetooth Low Energy Anchors that can reside inside the car. It is a Bluetooth Low Energy peripheral. Depending on the scenario, this peripheral can perform both Legacy (1M PHY) and Extended Long Range (500 kilobits per sec Coded PHY) advertising, searching for a CCC Digital Key-enabled device such as a smartphone.

There can be multiple Anchors inside a car. The Anchors must act as a single device and share information between them such as addresses, bonding data, or application-specific keys. The information must be shared such that a smartphone can connect to any one of the Anchors, depending on positioning and not detect any difference.

For the purposes of localization, the Digital Key Car Anchor acts either as a Channel Sounding Initiator or Reflector and as a Server/Client in the context of the Bluetooth LE Channel Sounding (BTCS). The Digital Key Car Anchor runs the localization algorithm using the local and remote distance measurement data.



Parent topic:*CCC Digital Key applications overview*

Digital Key Device application

The Digital Key Device demo application emulates a CCC Digital Key-enabled smartphone. It acts as a Bluetooth Low Energy central device, scanning for advertising coming from a Digital Key Car Anchor.

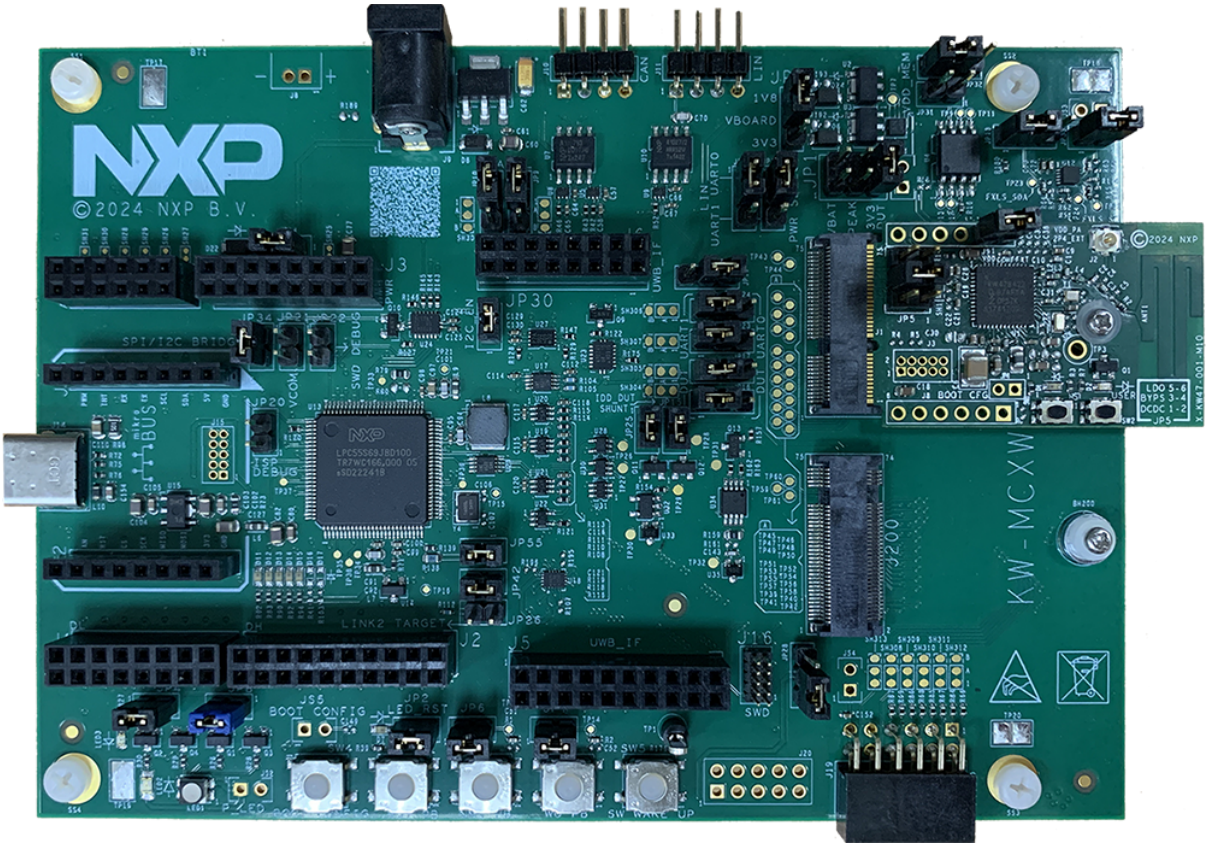
The figure below shows an example deployment of CCC Digital Key R3.

Anchor communicating with a smartphone (CCC) and a key fob (non-CCC)

Inside the car, there are two Bluetooth Low Energy Anchors connected to each other through Controller Area Network (CAN) bus. These Anchors are used to exchange security data and other information. An Anchor can connect to a CCC Digital Key R3-enabled smartphone and to a non-CCC key fob and can perform both advertising and scanning.

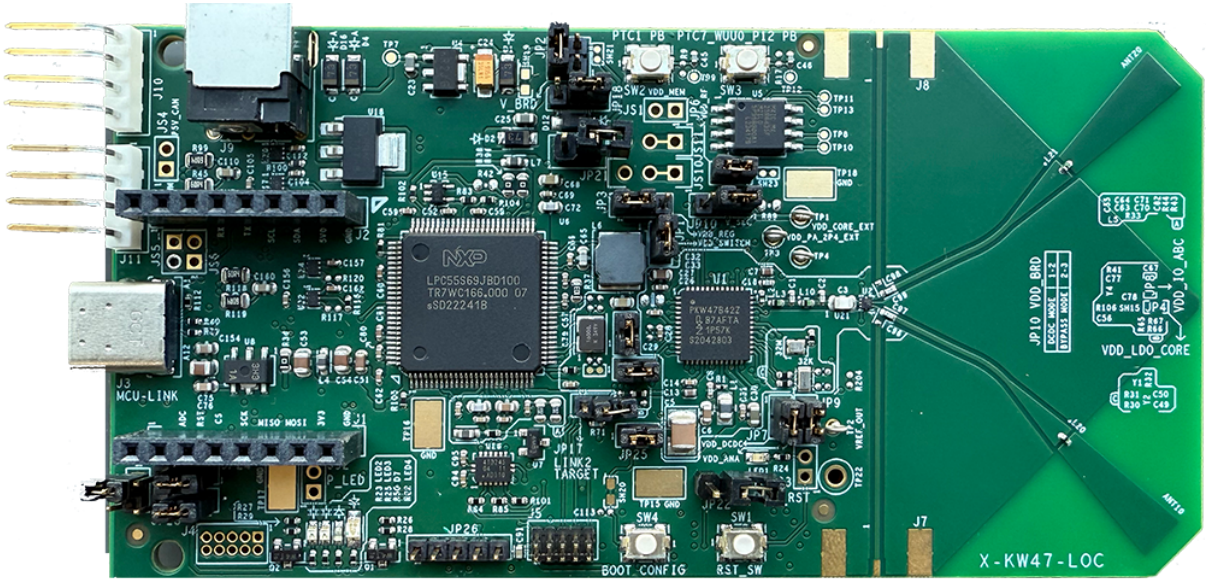
For the purposes of localization, the Digital Key Device acts as either a Channel Sounding Initiator or Reflector and as a Client/Server in the context of the BTCS. The BTCS Server stores the local measurement data and provides it to the BTCS Client.

Parent topic:*CCC Digital Key applications overview*



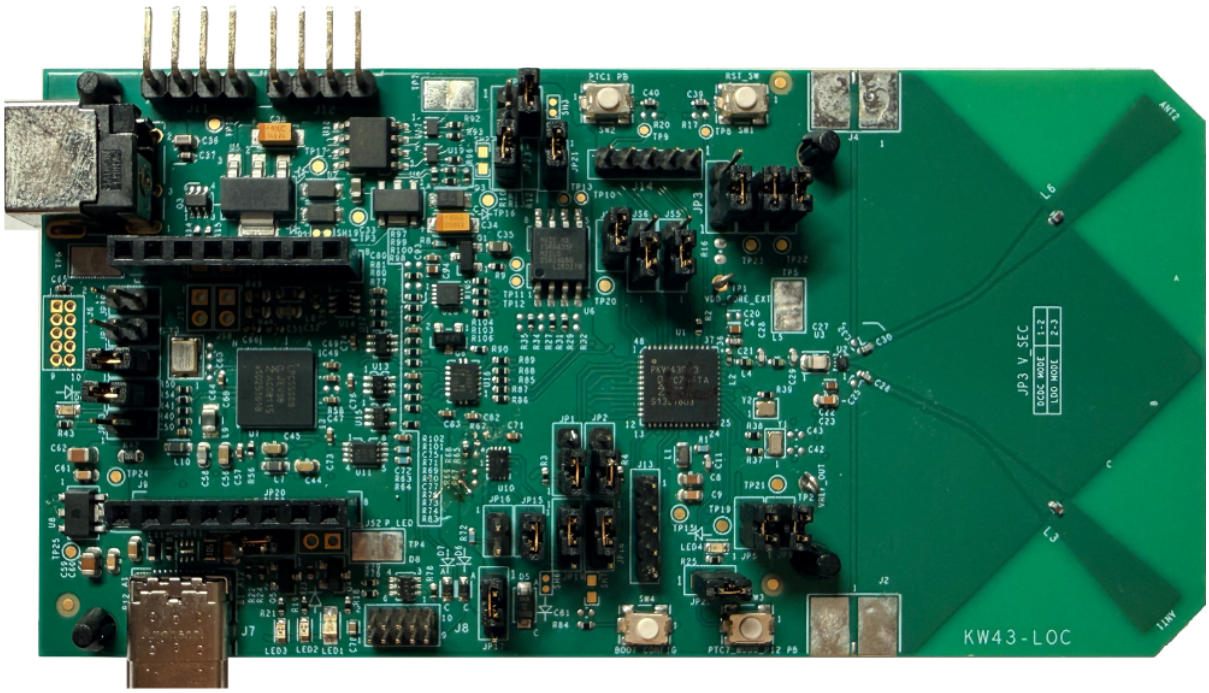
CCC Digital Key hardware platforms

The CCC Digital Key R3 demo applications with localization functionality support the following platforms that have Bluetooth Low Energy transceiver capabilities:

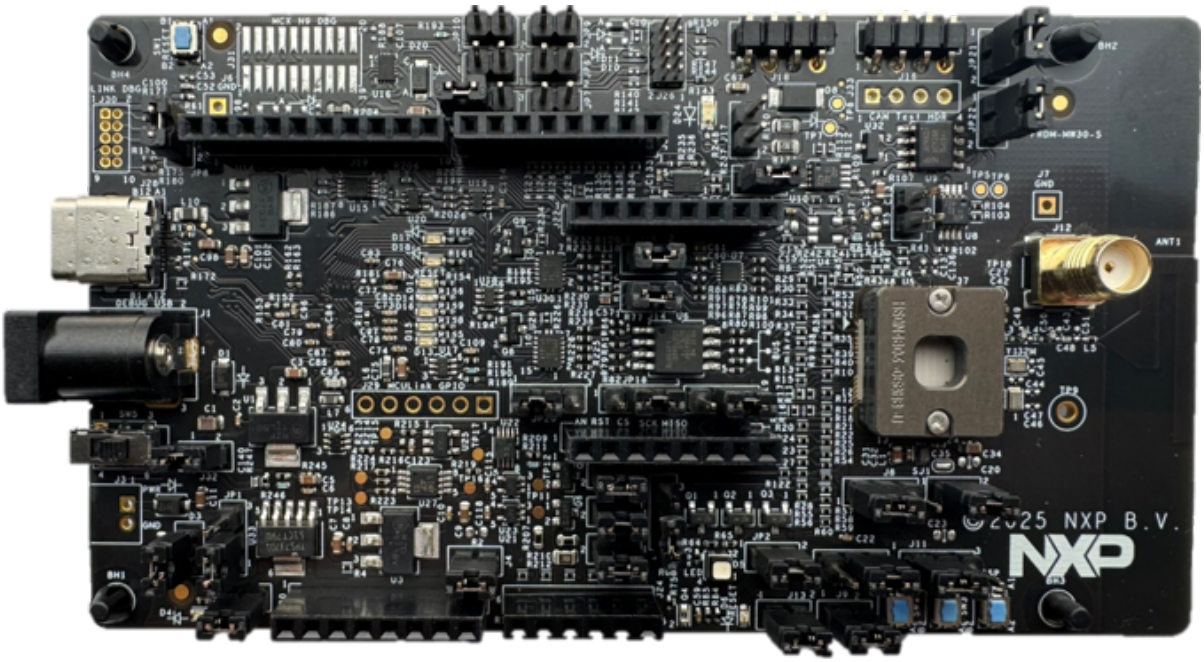


- KW47-EVK
- KW47-LOC board
- KW43-LOC board
- FRDM-KW43

The below figures show these boards.



KW47-EVK board



KW47-LOC board

KW43-LOC board

FRDM-KW43 board

Deploying CCC Digital Key application software

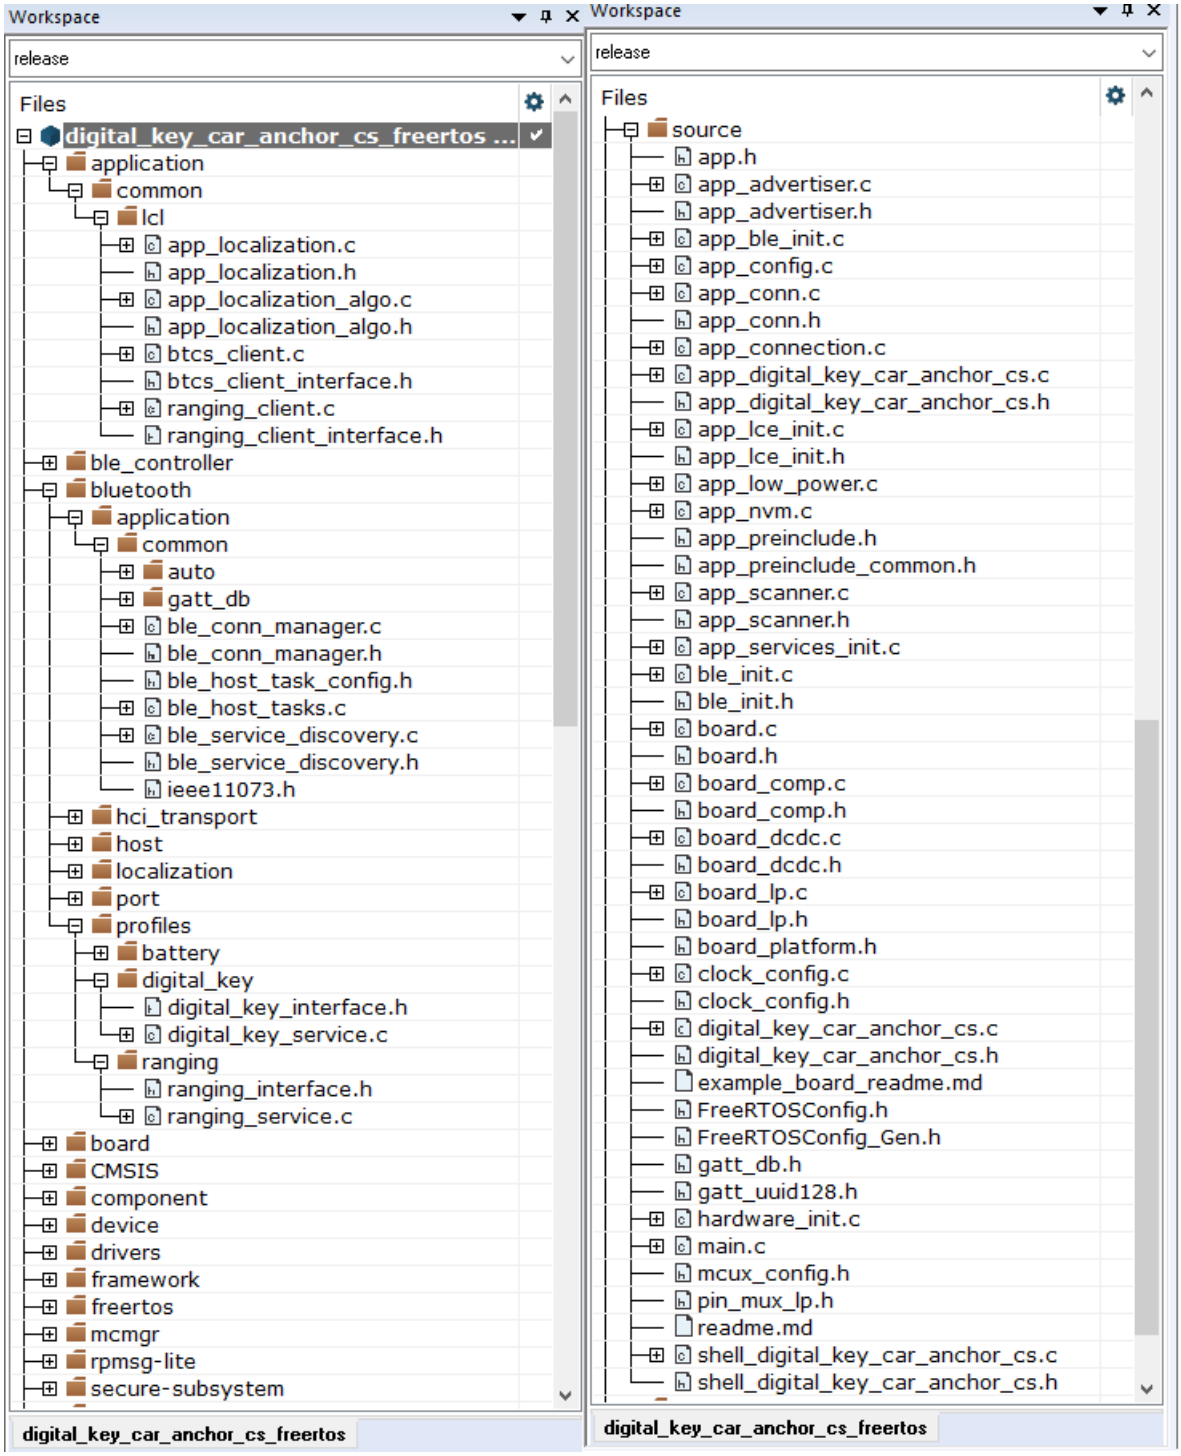
The software package includes the components necessary for CCC Digital Key R3 application development on the selected NXP platform. These components include:

- Bluetooth Low Energy Host software libraries
- Channel Sounding and Localization algorithm libraries
- NBU images binaries
- Examples of demo application projects corresponding to CCC Digital Key roles (Device and Car Anchor)
- Platform peripheral drivers, platform startup code, other generic platform software

Note: Prior to loading any wireless SDK example, update your NBU image with the provided binaries, with Channel Sounding (CS) support, in the following folder of the SDK:

../middleware/wireless/ble-controller/bin.

The demo applications were compiled and tested with **IAR Embedded Workbench for Arm** and **ARMGCC**. Users are recommended to use one of these tools.



To open, build, and run any example application, see the Bluetooth Low Energy Quick Start Guide document of the corresponding board. The CCC Digital Key R3 examples are built and run in the same fashion as Bluetooth Low Energy examples.

The application folder structure for the *digital_key_car_anchor_cs* project can be described as the following:

- The main application source files are the source/digital_key_car_anchor_cs.c and source/app_digital_key_car_anchor_cs.c.
- The files in bluetooth/profiles/digital_key implement the Digital Key Service defined by the CCC Digital Key R3 specification.
- The application files for the localization functionality, are /application/common/lcl/app_localization.c and application/common/lcl/app_localization_algo.c.
- The files /application/common/lcl/btcs_server_interface.h and /application/common/lcl/btcs_server.c implement the BTCS Server functionality.
- The files /application/common/lcl/btcs_client_interface.h and /application/common/lcl/btcs_client.c implement the BTCS Client functionality.

The below figure shows the application folder structure for the *digital_key_car_anchor_cs* project.

Application folder structure in workspace

Demo functionality overview

The two demo applications provided showcase the following Digital Key R3 features:

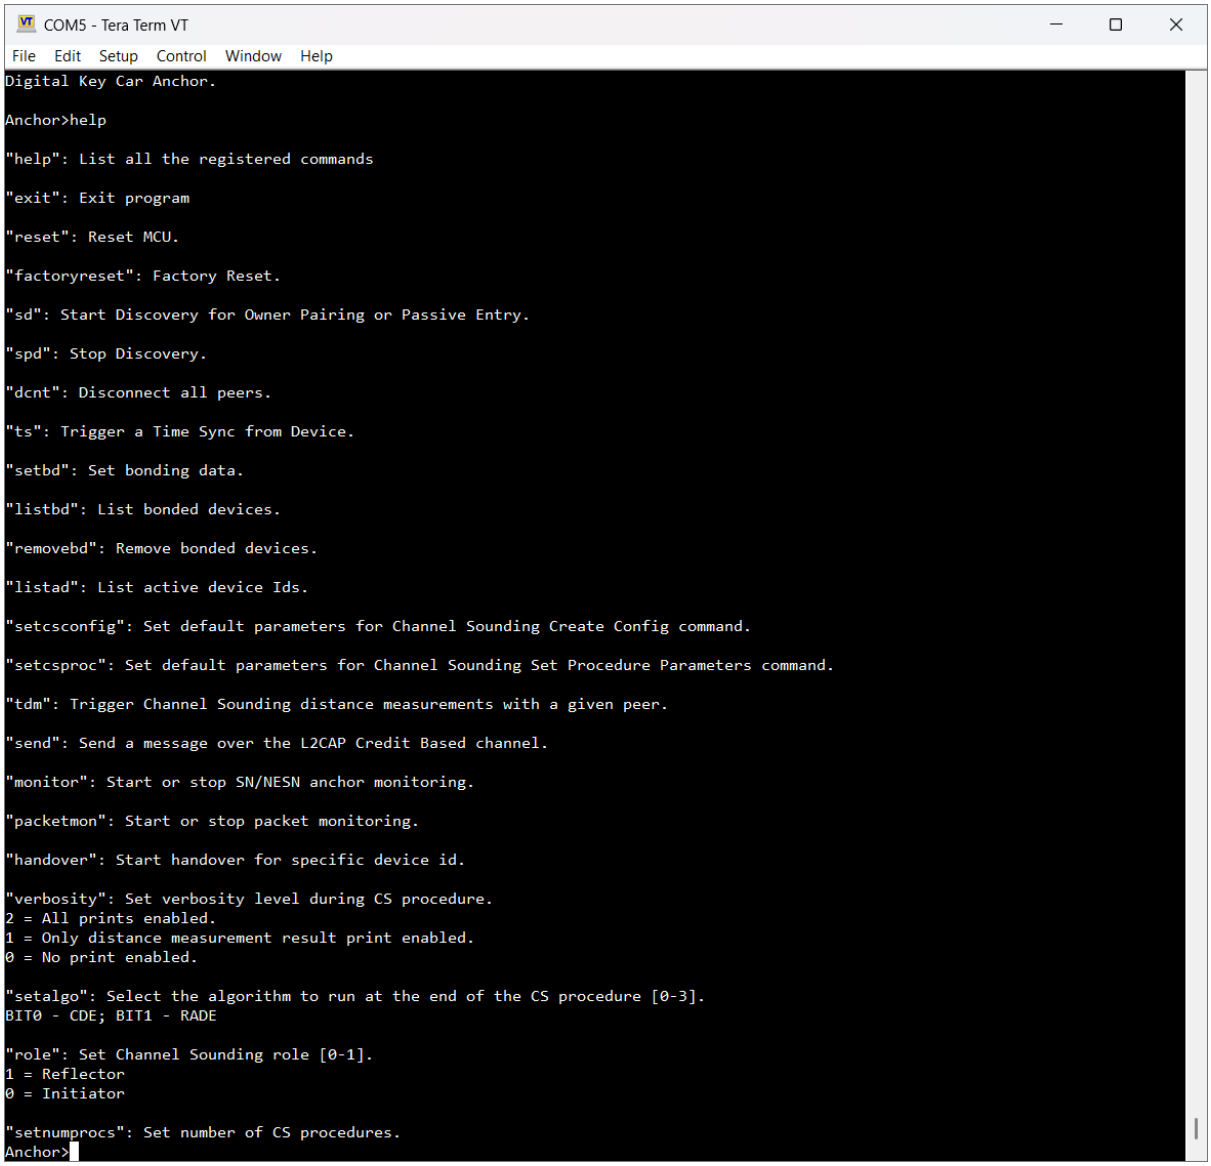
- Owner Pairing between a Device and a Car Anchor
- Passive Entry
- Synchronizing bonding data between Car Anchors
- Connection between a Car Anchor and a non-CCC key fob

The two demo applications showcase the following localization features:

- Distance measurement through Channel Sounding

- Distance measurement data transfer through L2CAP
- Ranging algorithms
  - Complex-domain Distance Estimation (CDE)
  - Rapid Accurate Distance Estimator (RADE)

The demo applications showcase the NXP proprietary Connection Handover and Anchor Monitoring features, and the A2B feature (secured synchronization of bonding data).



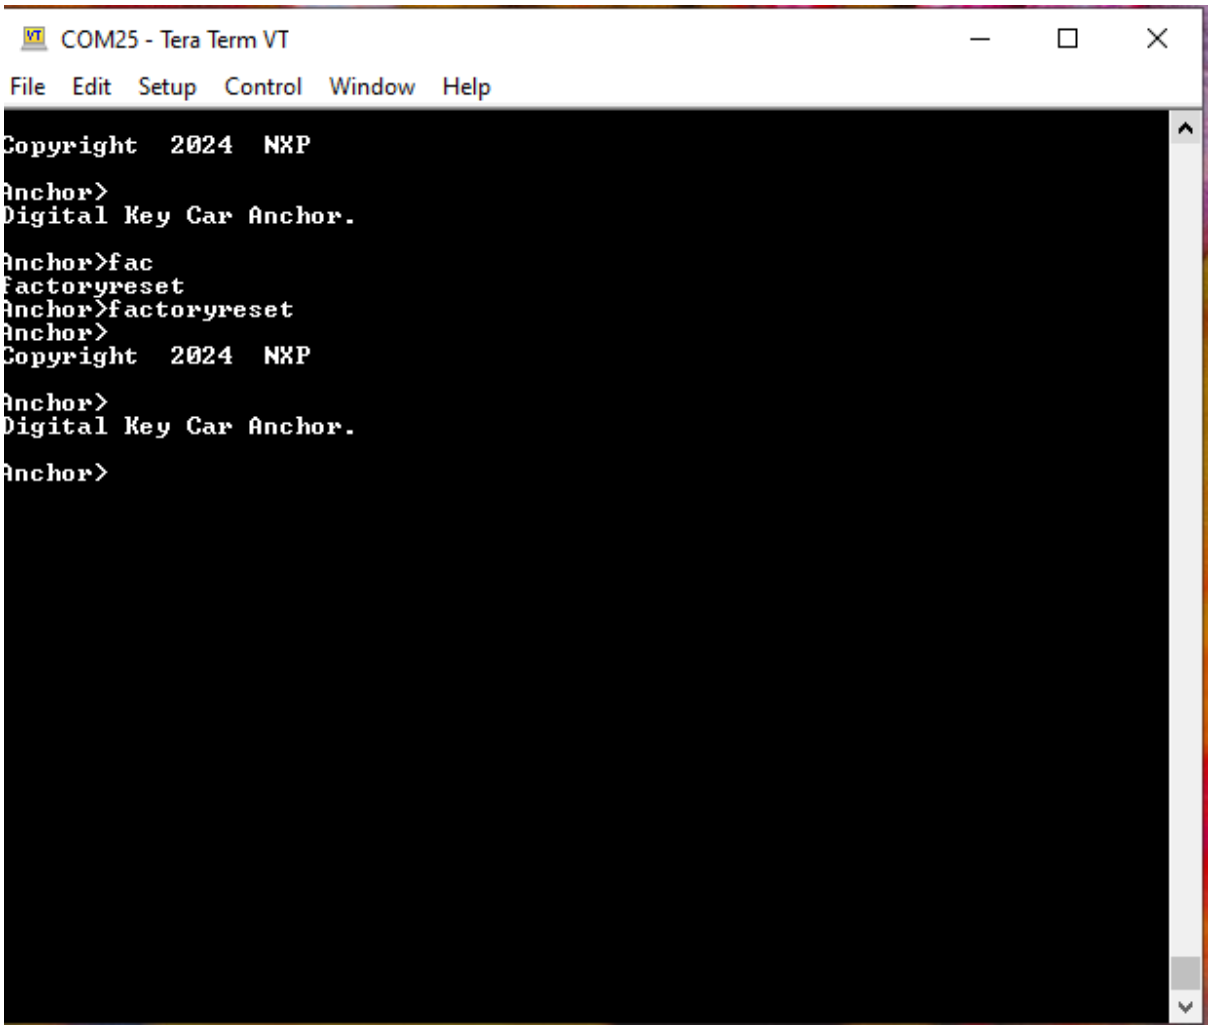
Running CCC Digital Key scenarios using the shell interface

The following CCC Digital Key R3 examples are provisioned by default with a shell command line interface accessible via a Terminal application such as Tera Term:

- Digital Key Car Anchor
- Digital Key Device

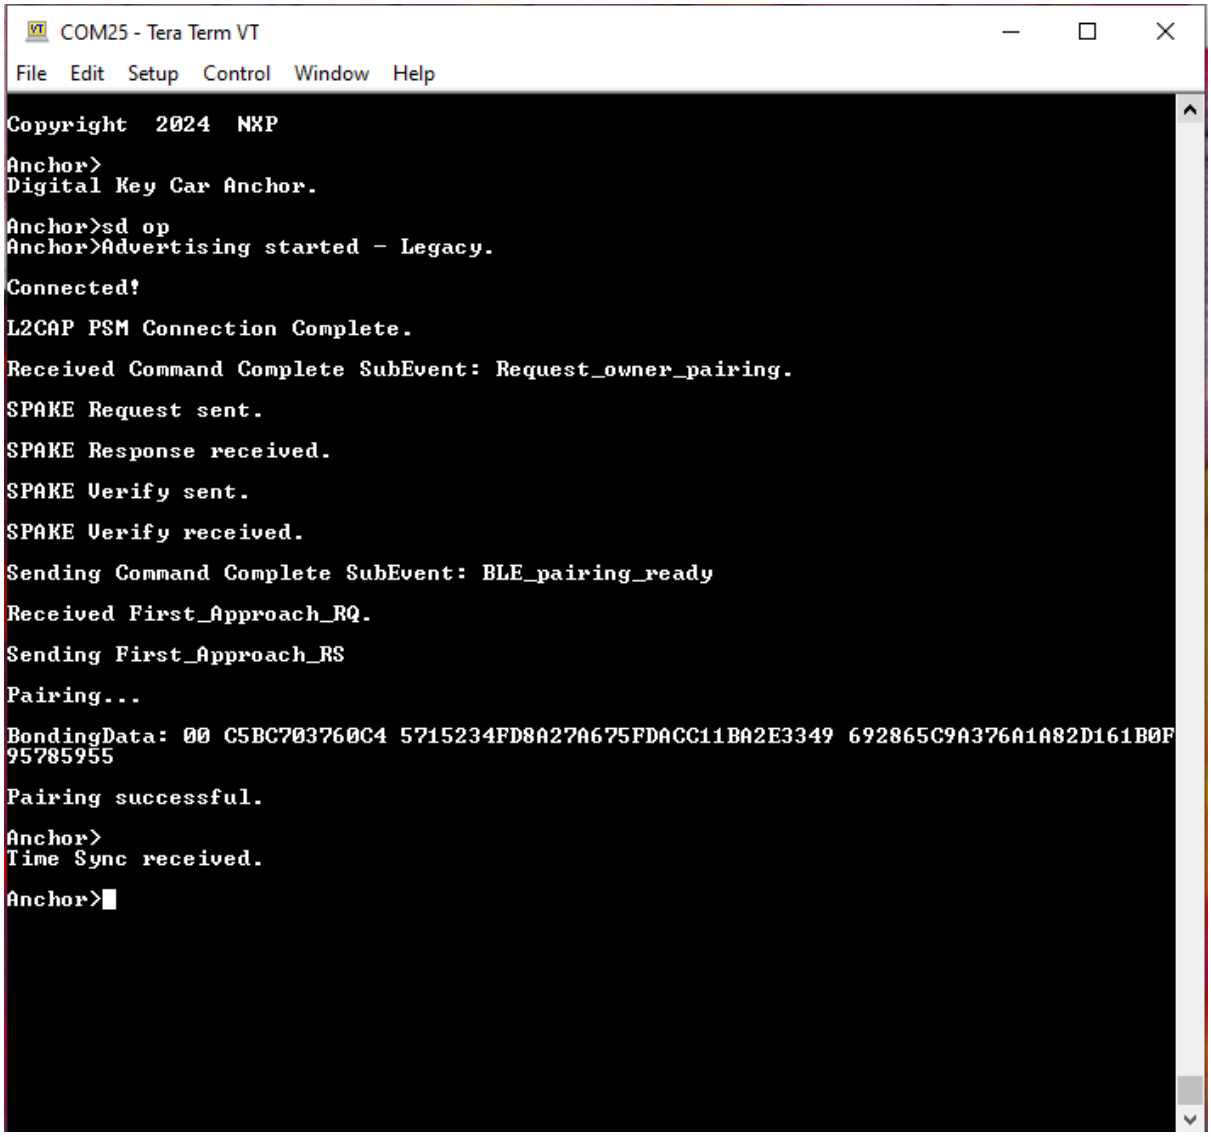
After you connect through the Terminal application and press the **RST** switch on the board, a welcome message appears. Enter the `help` command to display the list of available commands and their descriptions. See the figure below.

List of commands



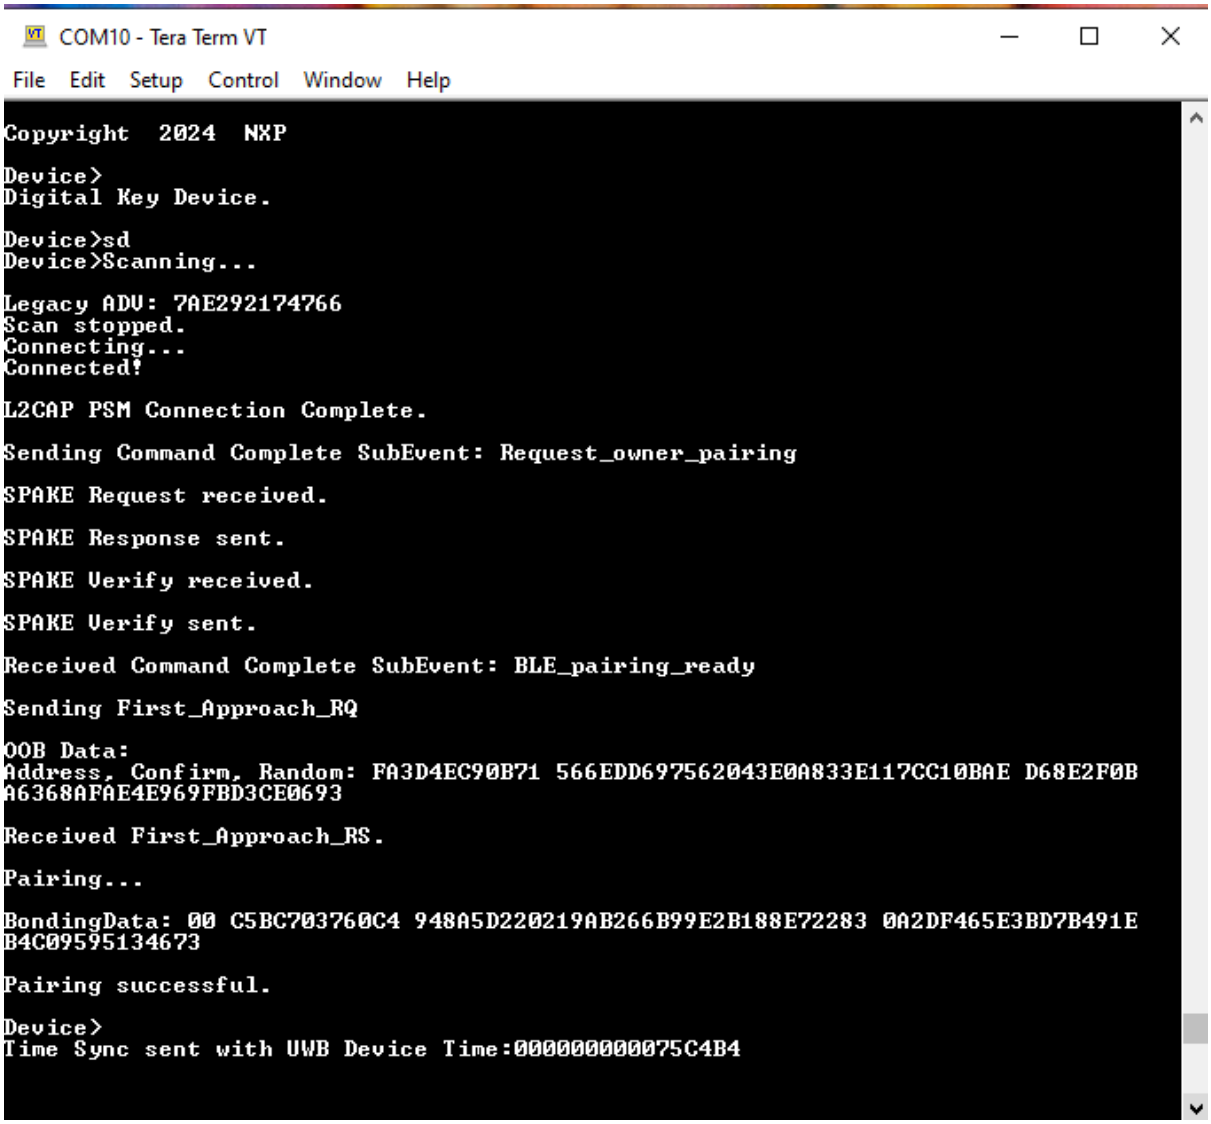
Owner Pairing scenario

Owner Pairing establishes a bond between the Digital Key Car Anchor and the Digital Key Device as per the CCC Digital Key R3 specification. The Car Anchor starts advertising using Legacy mode on the 1M PHY. The Device scans and connects. After establishing the connection, the Device performs service discovery. This step enables it to discover the DK Service and learn the PSM value it uses to open an L2CAP channel to the Car Anchor. This channel is used to exchange data and security information as part of the Bluetooth Low Energy Out-of-Band (OOB) pairing process. All security information exchanged consists of dummy messages. The applications do not currently implement any of the UWB and Secure Element functionality described by the CCC Digital Key R3 specifications (See *References*).



The first step is to run the "factoryreset" command on both boards in order to ensure no previous bonding data is present in non-volatile memory. Refer to the figure below.

Factory reset on Car Anchor



The next step is to run the "sd" command (Start Discovery) on the Device and the "sd op" command on the Car Anchor (Owner Pairing advertising differs from Passive Entry, using a single Legacy advertising set on the 1M PHY). The Car Anchor starts advertising while the Device scans. Since both boards have been factory reset, they follow the Owner Pairing flow. The command outputs are shown in the below figures.

Owner Pairing on Car Anchor

Owner Pairing on Device

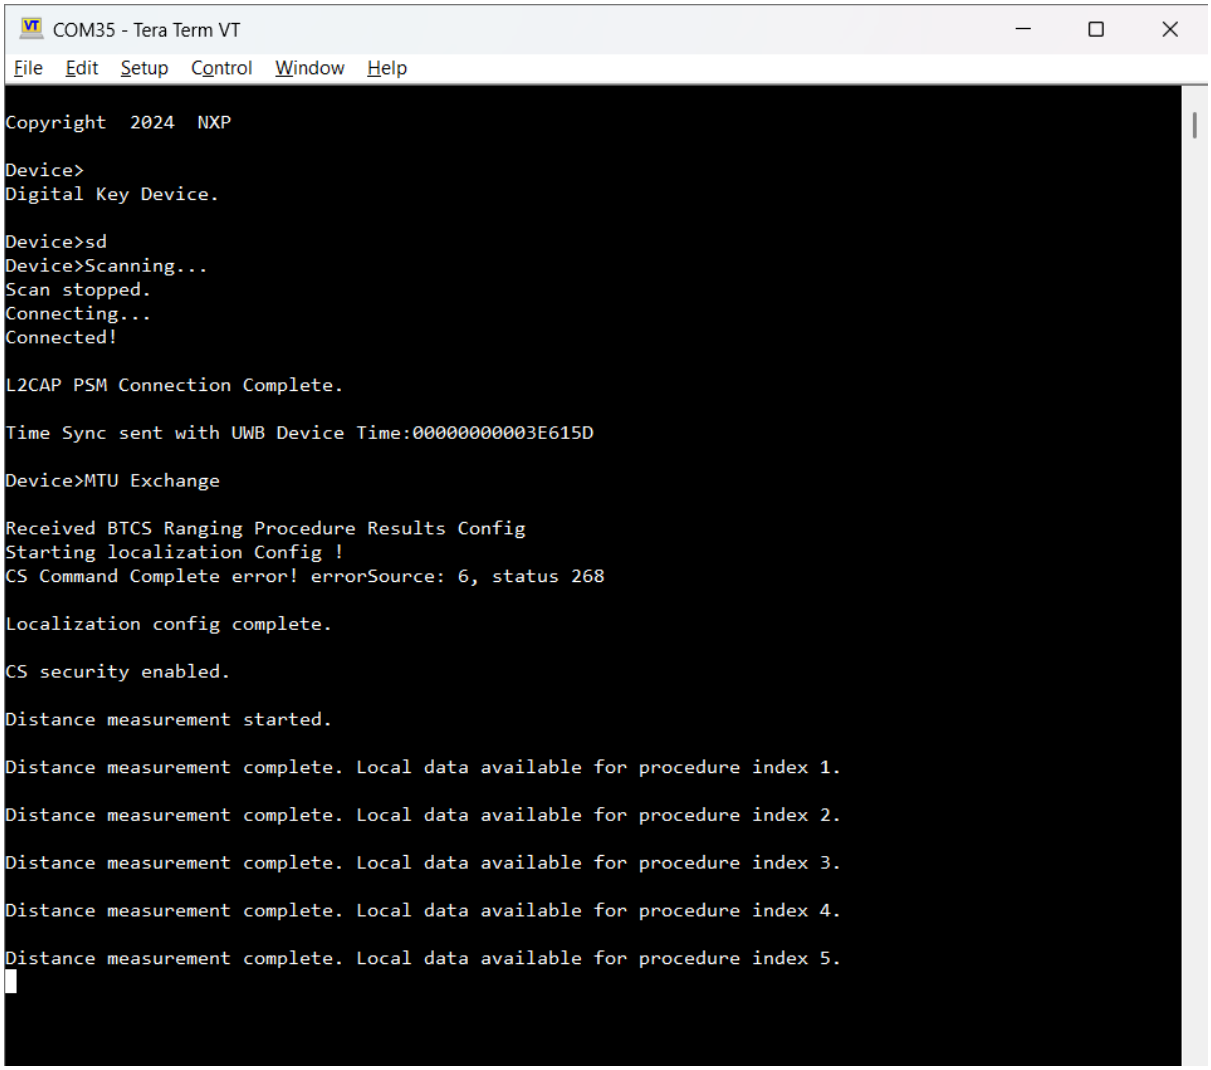
Parent topic:*Running CCC Digital Key scenarios using the shell interface*

Passive Entry scenario

The Passive Entry scenario runs after owner pairing between a Car Anchor and a Device has successfully completed. First, reset the recently paired boards using either the RST switch or the "reset" command in the shell. Alternatively, disconnect using the dcnt shell command.

Note: Do not perform a factory reset as this step removes the bonding information from the non-volatile memory.

After reset or disconnect, run the "sd" command on the Device and the "sd pe" command on the Car Anchor. For the Passive Entry scenario, the Car Anchor advertises using two sets, one Legacy on the 1M PHY and one Extended on the Coded PHY. Since bonding data is present, they follow the Passive Entry flow, stopping after the successful creation of the L2CAP channel. The application is functional after this step. Similar to the Owner Pairing scenario, the applications implement only the Bluetooth Low Energy functionality.



Note: The CCC specification requires using the coding scheme S=2 for Coded PHY advertising, equivalent to a data rate of 500 Kbits per second. To experiment with other coding schemes, change the advertising parameters in app_config.c for the *digital_key_car_anchor_cs* project.

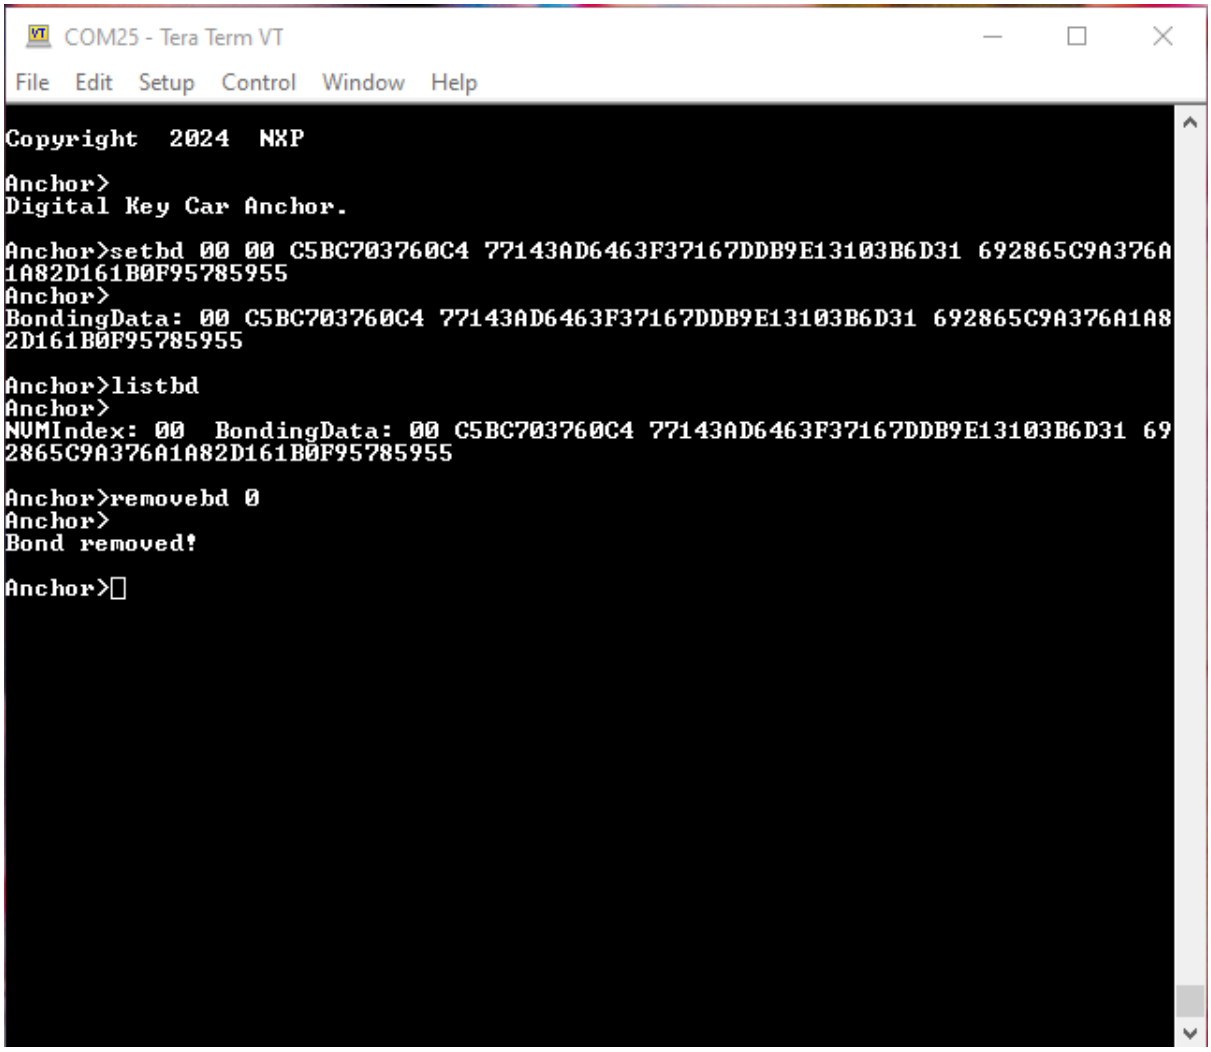
The output of the sd and sd pe commands is shown in the figures below.

Passive Entry on Car Anchor

Passive Entry on Device

Parent topic:*Running CCC Digital Key scenarios using the shell interface*

Synchronizing bonding data between Car Anchors



Note: The feature of Synchronizing bonding data between Car Anchors is only valid when the Advanced Secure Mode is disabled. This implies that the parameter (gAppSecureMode_d is set to 0 in the app_preinclude.h file. To synchronize bonding data when Advanced Secure Mode is enabled, refer to the section *Running the A2B scenario*.

Multiple Car Anchors can reside on a car, acting as a single Bluetooth Low Energy device as far as the Device is concerned. When the Device pairs and bonds with a Car Anchor, that bonding data must be shared with all other Anchors.

To showcase this functionality, the Car Anchor shell demo offers the "setbd" command. During owner pairing, the bonding data is displayed in the shell as seen in the Owner Pairing section. By passing this data to the "setbd" command on another Car Anchor, the Anchor is able to connect with the original Device and perform the Passive Entry flow. Currently only the Bluetooth Low Energy bonding data is transferred between Anchors. No CCC Digital Key R3-specific keys are exchanged. Saved bonding data can also be viewed using the "listbd" command and a specific bond can be removed using the "removebd" command. A bond can only be removed if a connection to that specific device is not currently active. The figure below also shows listing bonds and removing a bond.

The commands presented in this subsection are also supported on the Device for test purposes.

Adding bonding data to a Car Anchor

Note:

- To simulate Anchors residing on the same car, the Random Static Address required by the Digital Key protocol and the Identity Resolving Key are set at compile time for the *digital_key_car_anchor_cs* project. To simulate Anchors residing on different cars, change the values of the APP_BD_ADDR and APP_SMP_IRK macros in the *app_preinclude.h* file of the project.

Parent topic:*Running CCC Digital Key scenarios using the shell interface*

Running the Connection Handover scenario

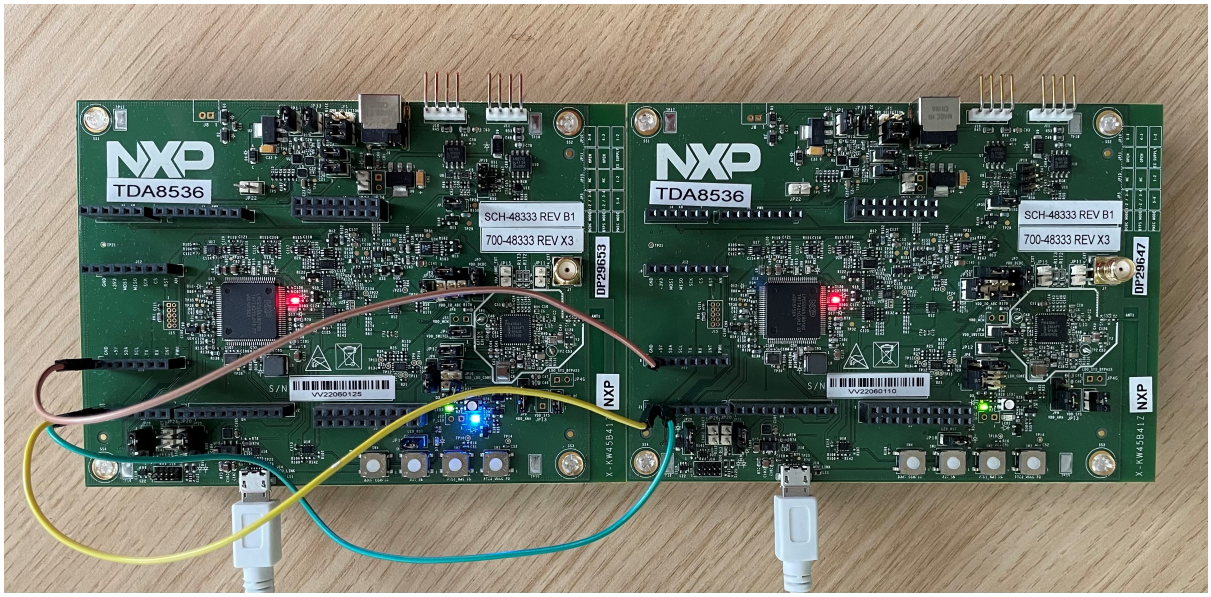
Connection Handover is an NXP proprietary feature that enables seamless transfer of a Bluetooth Low Energy connection from one peripheral to another while the central device remains unaware. The CCC Digital Key use case best exemplifies this scenario but is not limited to it. As a person carrying a phone moves around the vehicle, the Bluetooth Low Energy connection is transferred between Car Anchors to ensure the best user experience. From the point of view of the Device, it stays in the same initial connection.

The CCC Digital Key demos showcase the Connection Handover feature. The handover is performed on demand via a button press. In a real scenario, the handover is performed based on criteria such as RSSI. The following hardware platforms support this feature:

- KW47-EVK
- KW47-LOC board
- KW43-LOC board

- FRDM-KW43

Prerequisites:



- Three boards (two boards act as Car Anchors, one as a Device). The demo is limited to a maximum of two Car Anchors.
- The two Car Anchors must have a serial connection via the secondary UART. The UART connection stands in for a real deployment solution such as a CAN bus. The table below describes the connections for each supported board.

Board	UART RX ↔ TX	UART TX ↔ RX	GND
KW47-EVK	J1-1 ↔ J1-3	J1-3 ↔ J1-1	J13-8 ↔ J13-8
KW47-LOC	J2-3 ↔ J2-4	J2-4 ↔ J2-3	J2-8 ↔ J2-8
KW43-LOC	JP19-3 (UART0_RX PTA18) ↔ JS6-3 (UART0_TX PTA17)	JS6-3 ↔ JP19-3	J9-8 ↔ J9-8
FRDM-KW43	J22-1 (UART0_RX PTA18) ↔ JP19-1 (UART0_TX PTA17)	JP19-1 ↔ J22-1	J21-8 ↔ J21-8

Note: For KW43-LOC and FRDM-KW43, the current firmware configuration uses PTA18 for UART0_RX instead of PTA16 as shown in the schematic.

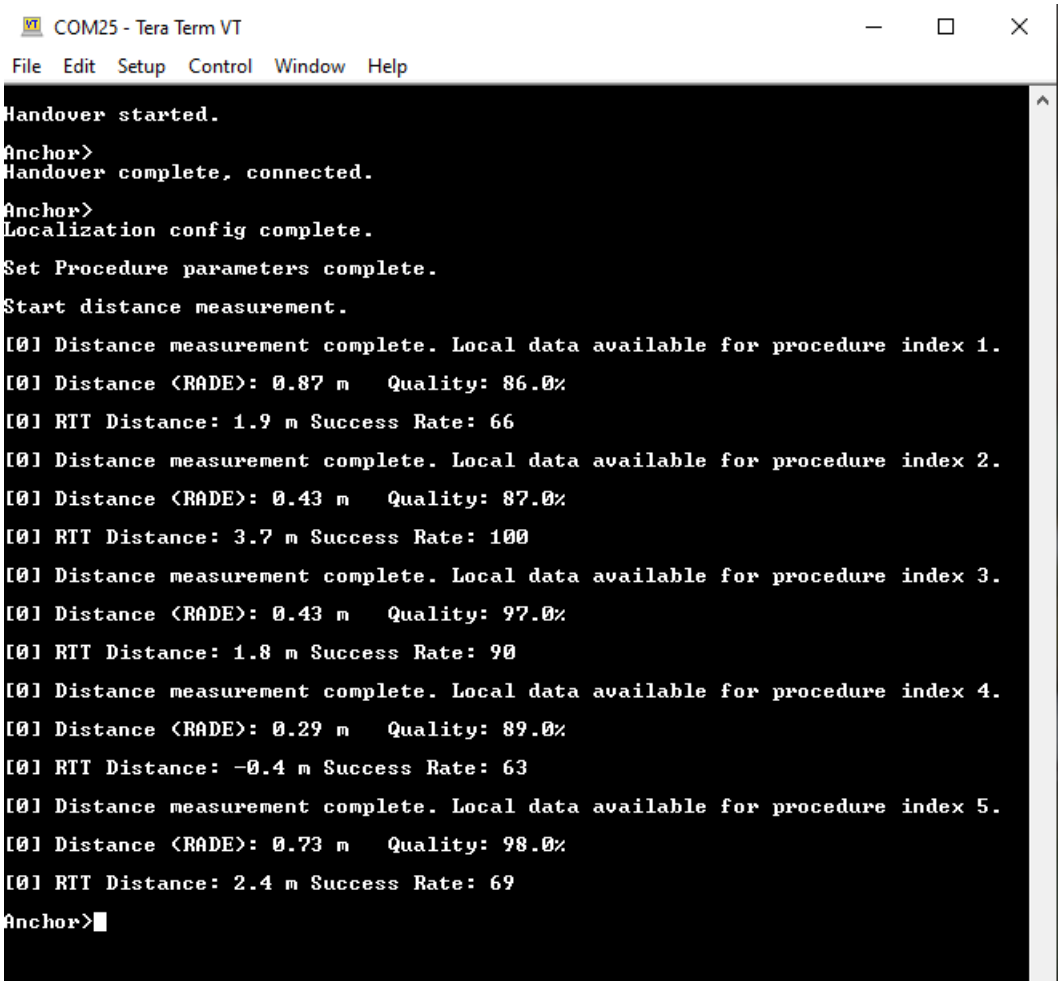
- The *gHandoverIncluded_d* macro must be set to `1` in `app_preinclude.h` for the ***digital_key_car_anchor_cs*** project.
- The CS configuration must exist on the initial Car Anchor before the first handover is performed, as detailed in the Demo steps below.

Two Car Anchors connected via the secondary UART

Demo steps:

- Connect a Car Anchor and a Device using the Passive Entry scenario as described in the section Passive Entry scenario.
- Press the **SW3** switch on the Car Anchor which is connected to the Device.
- The connection is handed over to the second Car Anchor as seen in console messages. LED2 also turns solid blue on the Car Anchor that takes over the connection.

- **Optional**: Use the "send" shell command on the Car Anchor that has taken over the connection. The message is displayed in the console on the Device, after the Passive Entry scenario has completed and CS procedures have run.
- The connection can also be continually handed over back and forth between the two Car Anchors. To perform this step, press the **SW3** switch on the Car Anchor that currently has the connection.

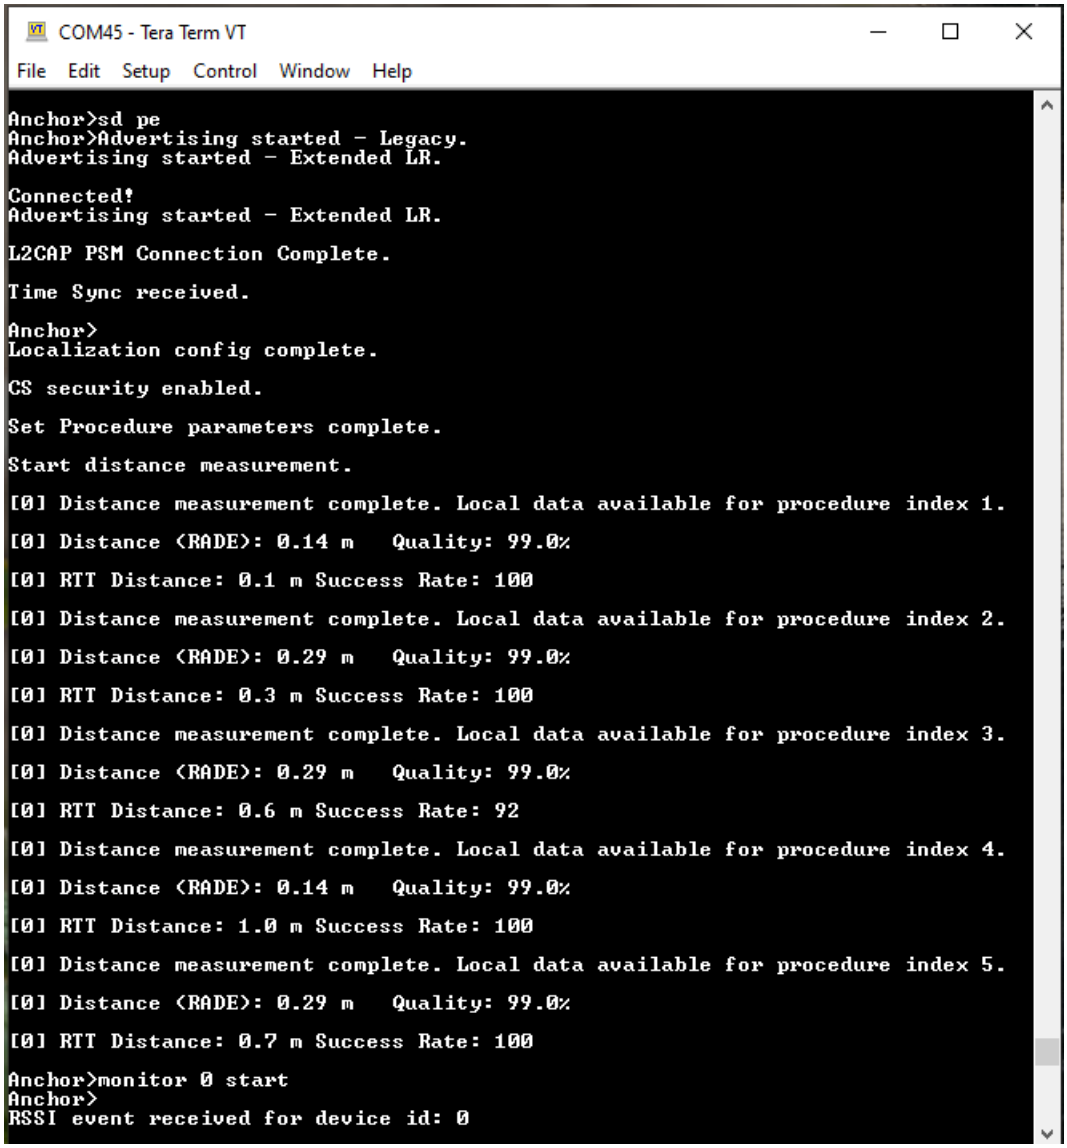


As shown in the below figure, the first Car Anchor performs the Passive Entry scenario, followed by the CS procedures resulting in distance measurements. The handover is then triggered via button press.

First Car Anchor performs the Passive Entry scenario and distance measurements

The figure below shows that the second Car Anchor takes over the connection. The default role for the Car Anchor is CS Initiator. Therefore, it automatically triggers new CS procedures resulting in distance measurements. The "tdm" shell command can be used to trigger new distance measurements from either the Device or the Car Anchor.

Second Car Anchor takes over the connection



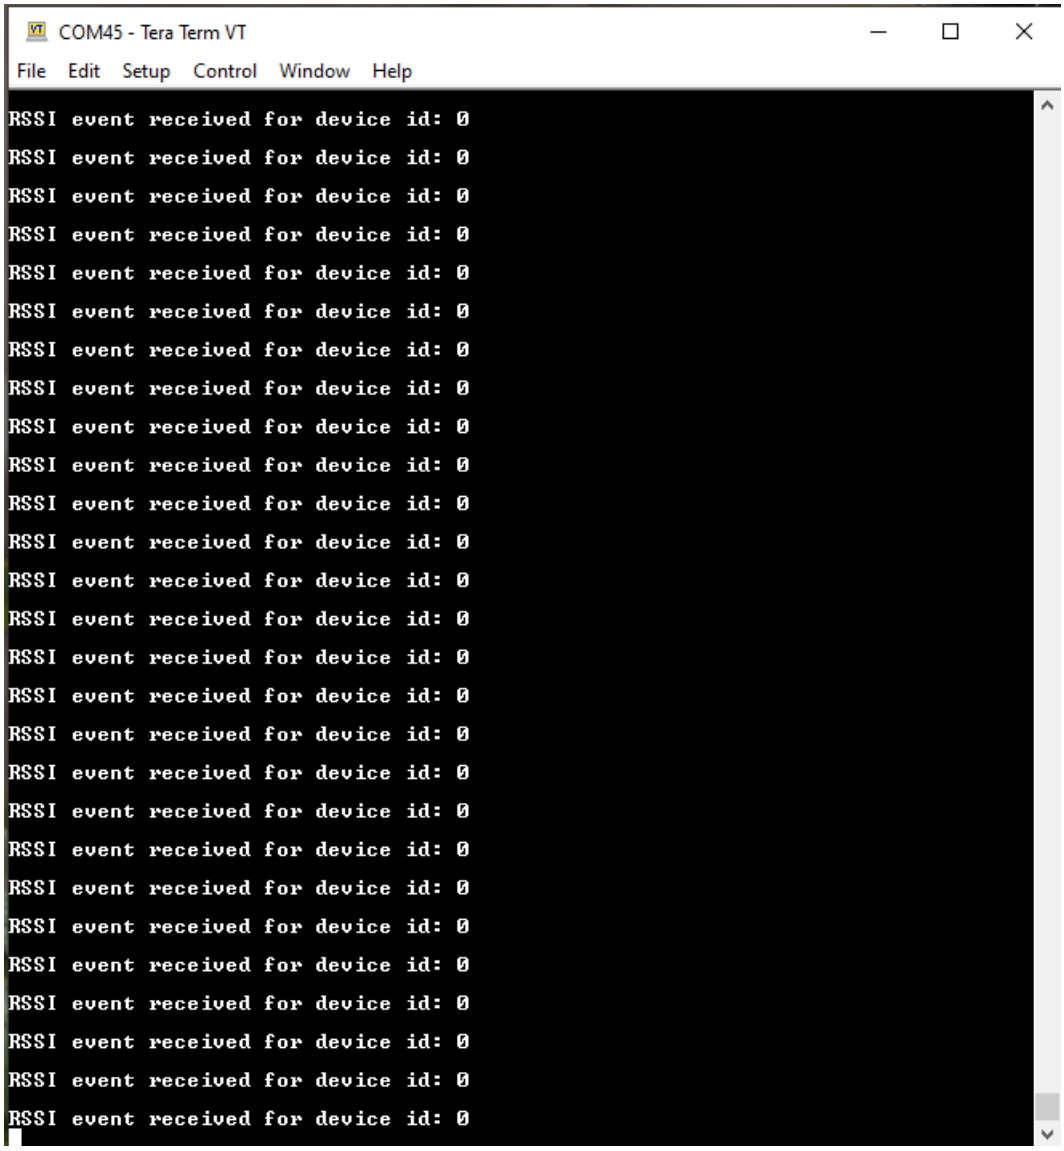
Running the Anchor Monitoring scenario

Anchor Monitoring is an NXP proprietary feature that allows a second Anchor to monitor the connection between the first Anchor and the Device. The feature requires the same hardware setup as used for the Connection Handover scenario. Note, however, that the Connection Handover scenario cannot be performed while Anchor Monitoring is in progress.

Demo steps:

1. Connect a Car Anchor and a Device using either the Owner Pairing or Passive Entry scenario as described in Owner Pairing scenario and Passive Entry scenario.

   Anchor has performed Owner Pairing and the `monitor start` **command is run**



2. Run the “monitor start” shell command on the Car Anchor, as shown in the figure below

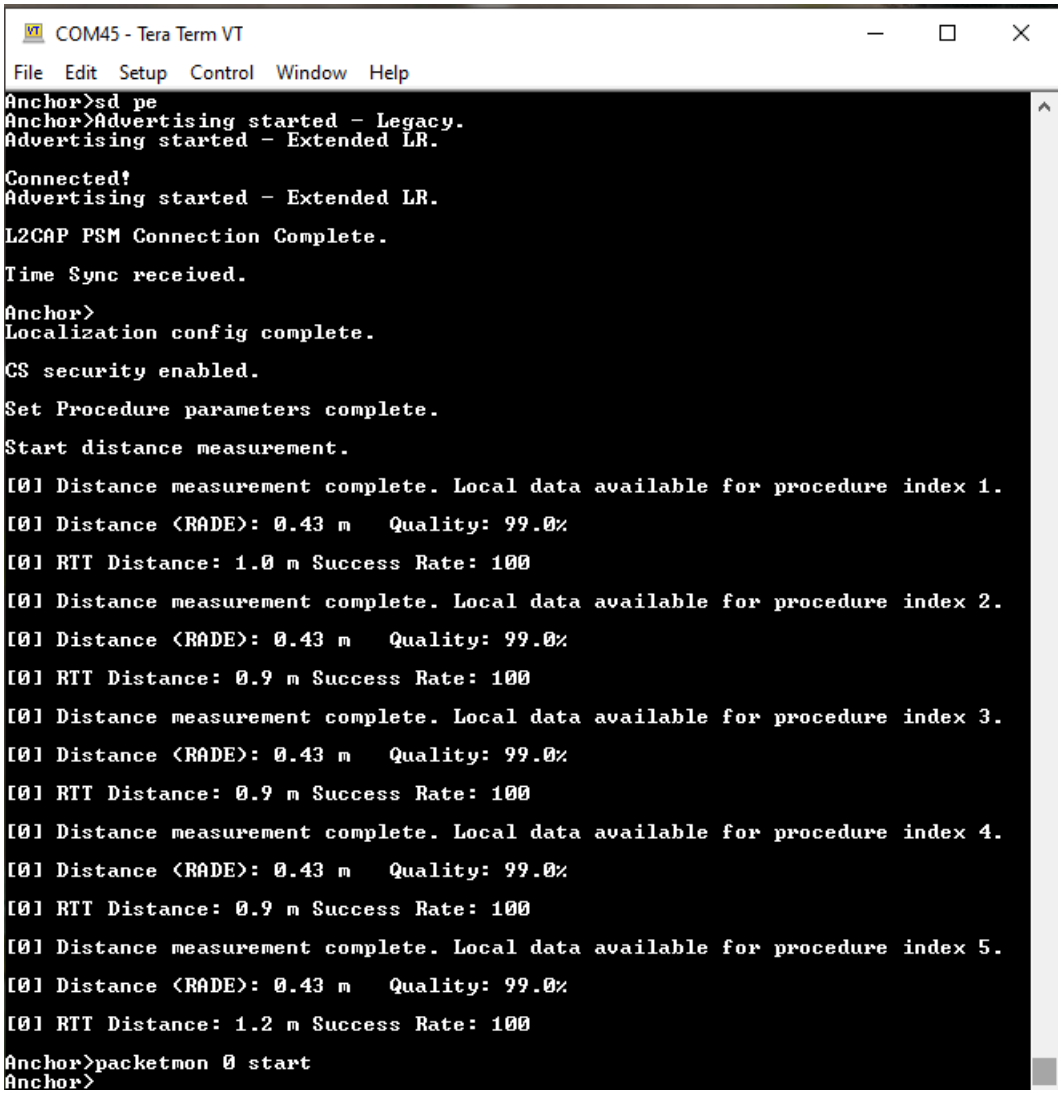
   The second Anchor has received the command over the serial interface and has started Anchor Monitoring

3. The second Car Anchor begins monitoring the connection and receives RSSI info events, which it forwards to the first Car Anchor. The received RSSI messages are then displayed on the console. This is shown in the figure below.

   The first Anchor displays RSSI events received from the second Anchor

4. To stop monitoring, run the `monitor stop` shell command on either of the Car Anchors (the second one is recommended, as its console is not flooded by RSSI event messages).

Parent topic:*Running the Connection Handover scenario*

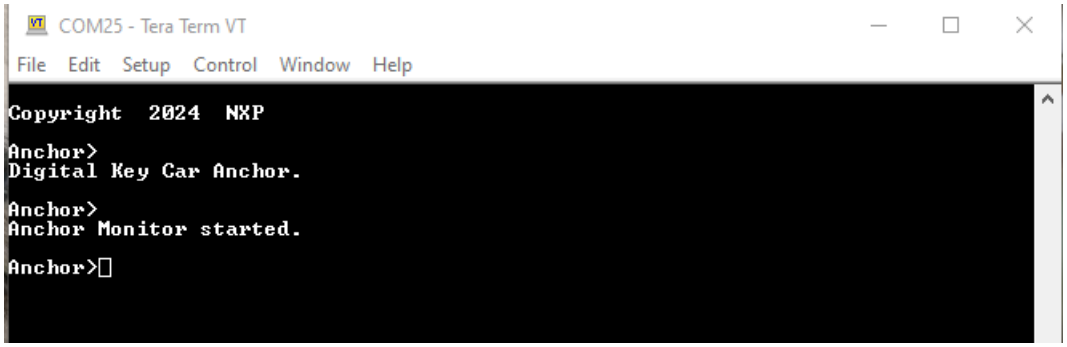


Running the Packet Monitoring scenario

Packet Monitoring is an NXP proprietary feature that allows a second Anchor to receive the packets from the connection between the first Anchor and the Device. The prerequisites are the same hardware setup as used for the *Running the Connection Handover scenario*. Note, however, that the Connection Handover scenario cannot be performed while Packet Monitoring is in progress. Packets received by the second Anchor are sent over the serial interface to the first Anchor for processing. The first Anchor determines the source of the packet based on bit 1 of the `status` parameter, which indicates whether the packet was sent by the central (`1`) or the peripheral (`0`), and displays the RSSI.

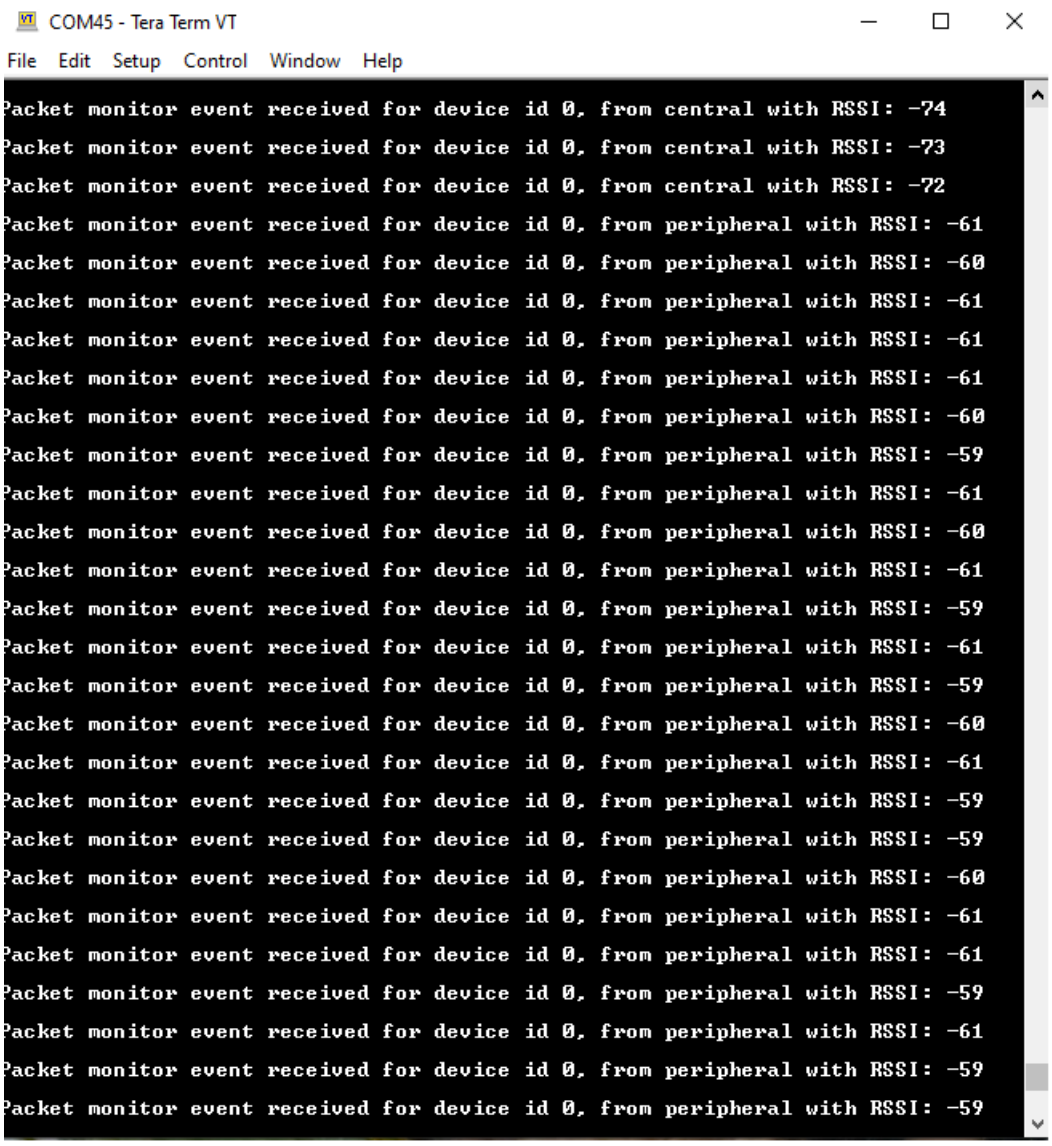
Demo steps:

1. Connect the first Anchor and a Device using either the Owner Pairing or Passive Entry scenario as described in Owner Pairing scenario and Passive Entry scenario.



Anchor has performed Owner Pairing and the `packetmon start` command is run

Anchor has performed Owner Pairing and the "`packetmon start`" command is run.



2. Run the packetmon start command on the first Anchor, as shown in the figure below.

The second Anchor starts Packet Monitoring after receiving the command over the serial interface

3. The second Anchor begins monitoring the connection and receives packet information, which it forwards to the first Anchor. See the figure below.

The first Anchor displays the RSSI and source device of the received packets from the second Anchor

4. The first Anchor receives the packet information from the second Anchor and determines the source of the packet based on bit 1 of the `status` parameter, which indicates whether the packet was sent by the central (1) or the peripheral (0). The source and the RSSI information is displayed in the console as shown in the preceding figure.
5. To stop monitoring, run the `packetmon stop` shell command on either Anchor. It is recommended to use the second Anchor, whose console is not flooded by packet information messages.

Parent topic:*Running the Connection Handover scenario*

Localization scenarios

Application configuration

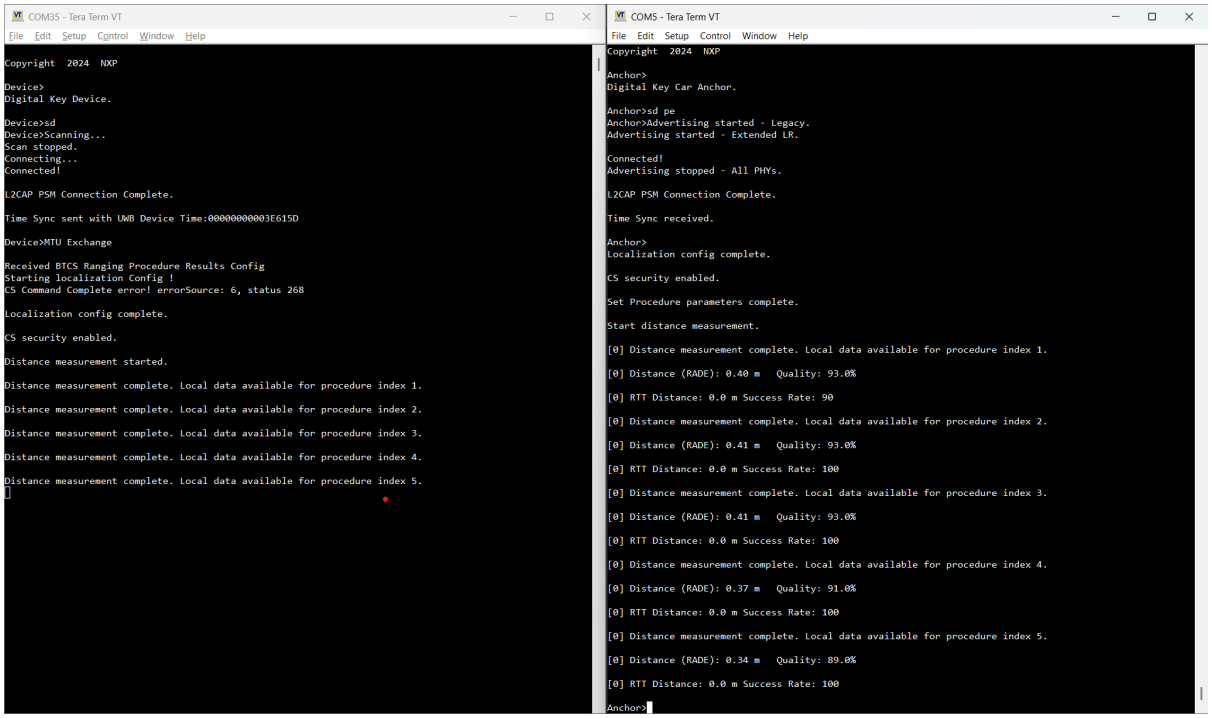
This section describes configuration options available for the applications. The configuration can be done either at compile time, by using macros added in the `app_preinclude.h` file of the respective sample, or at runtime, via shell commands. The available configurations are:

- The Channel Sounding role can be set through the `role` shell command at runtime only if there are no active connections. The default role is set through the `gCsDefaultRole_c` define in `app_preinclude.h`. In the default configuration, the Anchor is in the CS Initiator role (`gCsRoleInitiator_c`) and the Device is in the CS Reflector role (`gCsRoleReflector_c`).

- The number of Channel Sounding procedures to be run via the CS Procedure Repeat mechanism, for each triggered distance measurement. The default value can be set through the gCsProcRepeatMaxNumProcedures_c define. At runtime, the value can be changed using the setnumprocs command.
- The ranging algorithm to run once the local and remote measurement data is available. Each of the two supported algorithms can be disabled at compile time for code size reasons. By default, both are enabled. To disable an algorithm at compile time, define its respective macro with the value 0 inside app_preinclude.h. The macros are gAppUseCDEAlgorithm_d, gAppUseRADEAlgorithm_d. At runtime, the setalgo shell command can be used to configure the algorithm that runs upon completion of the CS procedure and data transfer. Any combination of algorithms can be selected. By default, RADE is selected.
- The timing information display feature can be activated by setting the gAppCsTimeInfo_d macro to value 1 inside app_preinclude.h. Additional timing information such as the duration of the CS config phase, CS procedure, BTCS transfer, and running of the algorithms is displayed on the console.
- The BTCS L2CAP transfer watchdog is an **NXP proprietary extension** (the CCC BTCS specification does not define any timeout for the L2CAP measurement transfer). When the CS procedure auto-restart loop is enabled on the BTCS client, this watchdog ensures the loop does not stall if a BTCS L2CAP transfer is lost or never completes. The feature is client-side only and is always enabled. The watchdog timeout duration in seconds can be tuned through the gBtcsTimeoutSeconds_c macro (default 3). If a transfer does not complete before the timeout expires, the watchdog only restarts the CS procedure loop when the full procedure sequence (maxNumProcedures) has been reached; otherwise it simply returns to waiting for the next procedure's measurement data.

For better performance and user experience, the optional LE Coded PHY advertising should be disabled by setting gAppLeCodedAdvEnable_d to 0 inside app_preinclude.h on the Anchor.

- Maximum concurrent Channel Sounding procedures**: Configure the maximum number of Channel Sounding procedures that can run simultaneously across all connections using the gChannelSoundingMaxConcurrentProcedures_c define in app_preinclude.h.



Parent topic:*Localization scenarios*

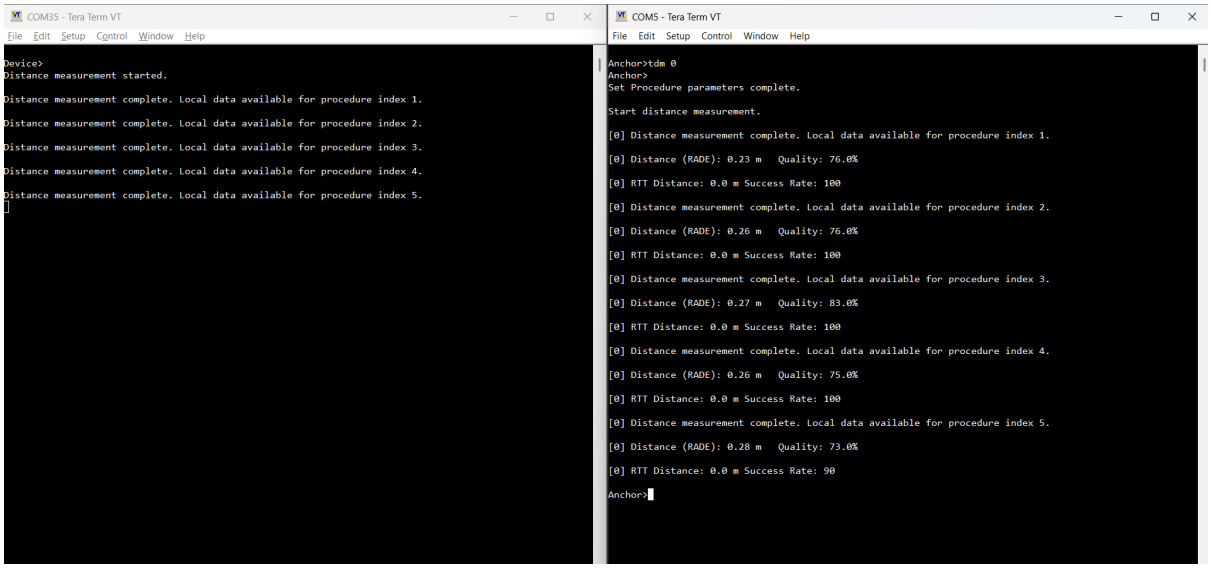
Localization after passive entry

The localization process starts automatically after the Passive Entry scenario is completed. The CS Initiator performs the CS setup and starts a number of gCsProcRepeatMaxNumProcedures_c procedures. After each procedure, the Device's local data is transmitted through BTCS to the Anchor. After the Anchor collects the data, it runs the selected algorithm(s) and displays the measured distance (meters) in the console.

The below figure shows the output of the localization process after each of the five measurements completed successfully and the distance is displayed.

Output of the localization process

Parent topic:*Localization scenarios*



Localization on demand and other shell commands

Localization can also be performed on demand via the tdm shell command. The command can be used in two ways:

- tdm - Triggers distance measurement on all connected devices
- tdm <peerId> - Triggers distance measurement on the specified peer device (where peerId is the device ID of the peer)

As shown in the figure below, the Device triggers the localization process, and the default 5 measurements complete successfully.

Triggering the localization process

Other available shell commands are:

- setcsconfig: This command overwrites the default parameters for the *Channel Sounding Create Config* command. It updates only the parameters that are explicitly specified; any parameter that is not provided retains its current value. The syntax is:

  setcsconfig <peerId> <paramName> <value> [<paramName> <value> ...]

  where <peerId> is the device ID of the peer, followed by one or more <paramName> <value> pairs. The supported parameter names and their accepted values are:

  - mainmodetype: CS mode to be used as main mode during the CS procedure for this configuration. Possible values:
    - 1 (CS mode-1)
    - 2 (CS mode-2)
    - 3 (CS mode-3)
  - submodetype: CS mode to be used as submode during the CS procedure for this configuration. Possible values:
    - 1 (CS mode-1)
    - 2 (CS mode-2)
    - 3 (CS mode-3)
    - 255 (no submode used)
  - mainmodeminsteps: Lower bound of the range of main mode CS steps to be executed before a submode CS step is executed during the CS procedure. Range:
    - 1 to 255
  - mainmodemaxsteps: Higher bound of the range of main mode CS steps to be executed before a submode CS step is executed during the CS procedure. Range:
    - 1 to 255
  - mainmoderepetition: Number of main mode CS steps repeated from the previous CS subevent at the beginning of the current CS subevent. Range:
    - 0 to 3
  - mode0steps: Number of CS mode-0 steps to be included at the beginning of each CS subevent. Range:\
    - 1 to 3
  - role: CS role. Possible values:
    - 0 (initiator)
    - 1 (reflector)
  - rtttype: RTT variant to be used during the CS procedure. Possible values:
    - 0 (RTT AA only)
    - 1 (RTT with 32-bit sounding sequence)
    - 2 (RTT with 96-bit sounding sequence)
    - 3 (RTT with 32-bit random sequence)
    - 4 (RTT with 64-bit random sequence)
    - 5 (RTT with 96-bit random sequence)
    - 6 (RTT with 128-bit random sequence)
  - channelmap: 80-bit map in big endian order indicating channels to be used for the CS procedure. The default value is fcff7ffcffffffffff1f (all channels used except 0, 1, 23-25 and 77-78). Bit 79 is reserved for future use. At least 15 channels must be enabled.

  - channelmaprepetition: Number of times the channel map will be cyled through for non-mode-0 steps within a CS procedure. Range:
    - 1 to 255.
  - channelselectiontype: Channel selection type. Possible values:
    - 0 (Channel Selection Algorithm #3b)
    - 1 (Channel Selection Algorithm #3c)
  - cssyncphy: PHY to be used for CS_SYNC exchanges during the CS procedure for the specified CS configuration. Possible values:
    - 1 (LE 1M PHY)
    - 2 (LE 2M PHY)
    - 3 (LE 2M 2BT PHY) - if supported at Link Layer level

  Example: setcsconfig 0 mode0steps 3 cssyncphy 2 updates only the mode-0 steps and the CS_SYNC PHY, leaving all other parameters unchanged.

- setcsproc: This command overwrites the default parameters for the *Channel Sounding Set Procedure Parameters* command. It updates only the parameters that are explicitly specified; any parameter that is not provided retains its current value. The syntax is:

  setcsproc <peerId> <paramName> <value> [<paramName> <value> ...]

  where <peerId> is the device ID of the peer, followed by one or more <paramName> <value> pairs. The supported parameter names and their accepted values are:

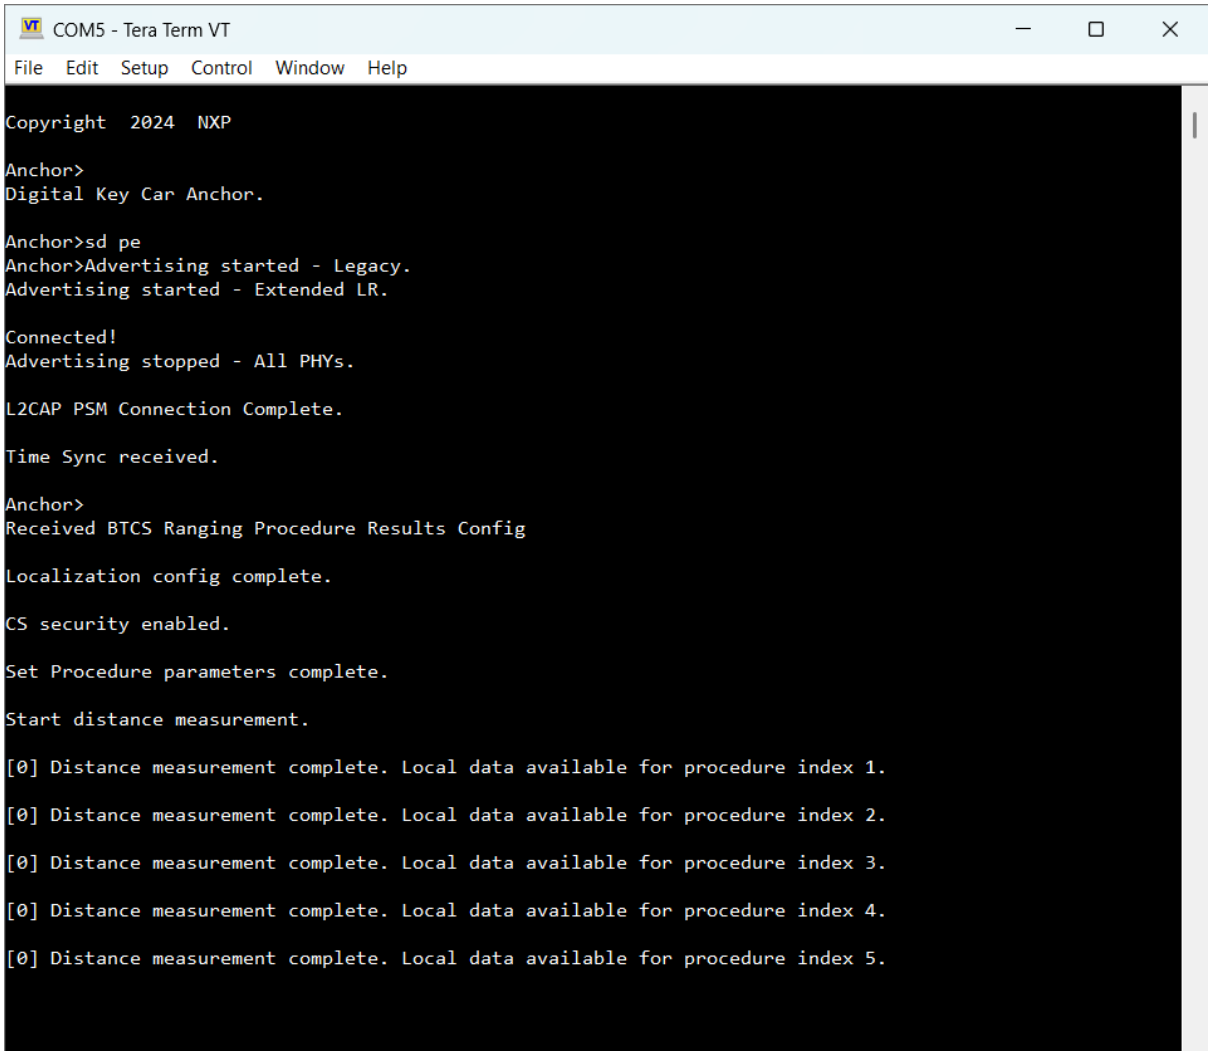
  - maxprocedureduration: Maximum duration for each CS procedure. Range:
    - 1 to 65535 (units of 0.625ms)
  - minperiodbetweenprocedures: Minimum number of connection events between consecutive CS procedures. Range:
    - 1 to 65535
  - maxperiodbetweenprocedures: Maximum number of connection events between consecutive CS procedures. Range:
    - 1 to 65535
  - maxnumprocedures: Maximum number of CS procedures to be scheduled. Possible values:
    - 0 (CS procedures to continue until disabled)
    - 1 to 65535
  - minsubeventlen: Minimum suggested duration for each CS subevent in microseconds. Range:
    - 1250 microseconds to 3.999999 seconds
  - maxsubeventlen: Maximum suggested duration for each CS subevent in microseconds. Range:
    - 1250 microseconds to 3.999999 seconds
  - antcfgindex: Antenna Configuration Index as described in the Core specification. Range:
    - 0 to 7
  - snrcontrolinit: SNR Control to be applied to the Initiator in the CS procedure (if supported at Link Layer level). Possible values:
    - 0 (SNR control adjustment of 18 dB)
    - 1 (SNR control adjustment of 21 dB)

        * 2 (SNR control adjustment of 24 dB)
        * 3 (SNR control adjustment of 27 dB)
        * 4 (SNR control adjustment of 30 dB)
        * 255 (SNR control is not to be applied)
    - snrcontrolrefl: SNR Control to be applied to the Reflector in the CS procedure (if supported at Link Layer level). Possible values:
        * 0 (SNR control adjustment of 18 dB)
        * 1 (SNR control adjustment of 21 dB)
        * 2 (SNR control adjustment of 24 dB)
        * 3 (SNR control adjustment of 27 dB)
        * 4 (SNR control adjustment of 30 dB)
        * 255 (SNR control is not to be applied)

    Example: setcsproc 0 minsubeventlen 2500 antcfgindex 1 updates only the minimum subevent length and the antenna configuration index, leaving all other parameters unchanged.

- verbosity: Sets the verbosity level during the CS procedure.
- setnumprocs: This command overwrites the default value gCsProcRepeatMaxNumProcedures_c parameter for the CS Procedure Repeat. It takes the following parameters, in the order below:
    - peerId
    - maxnumprocedures: Number of procedures in hex format. Example: setnumprocs 0 0x0005. Value 0x0000 means infinite repeats.
- loop: This command toggles the automatic restart of the CS procedure (whether with CS Procedure Repeat enabled or not) upon its end. By default, the CS procedure will not restart automatically. **Parent topic:***Localization scenarios*

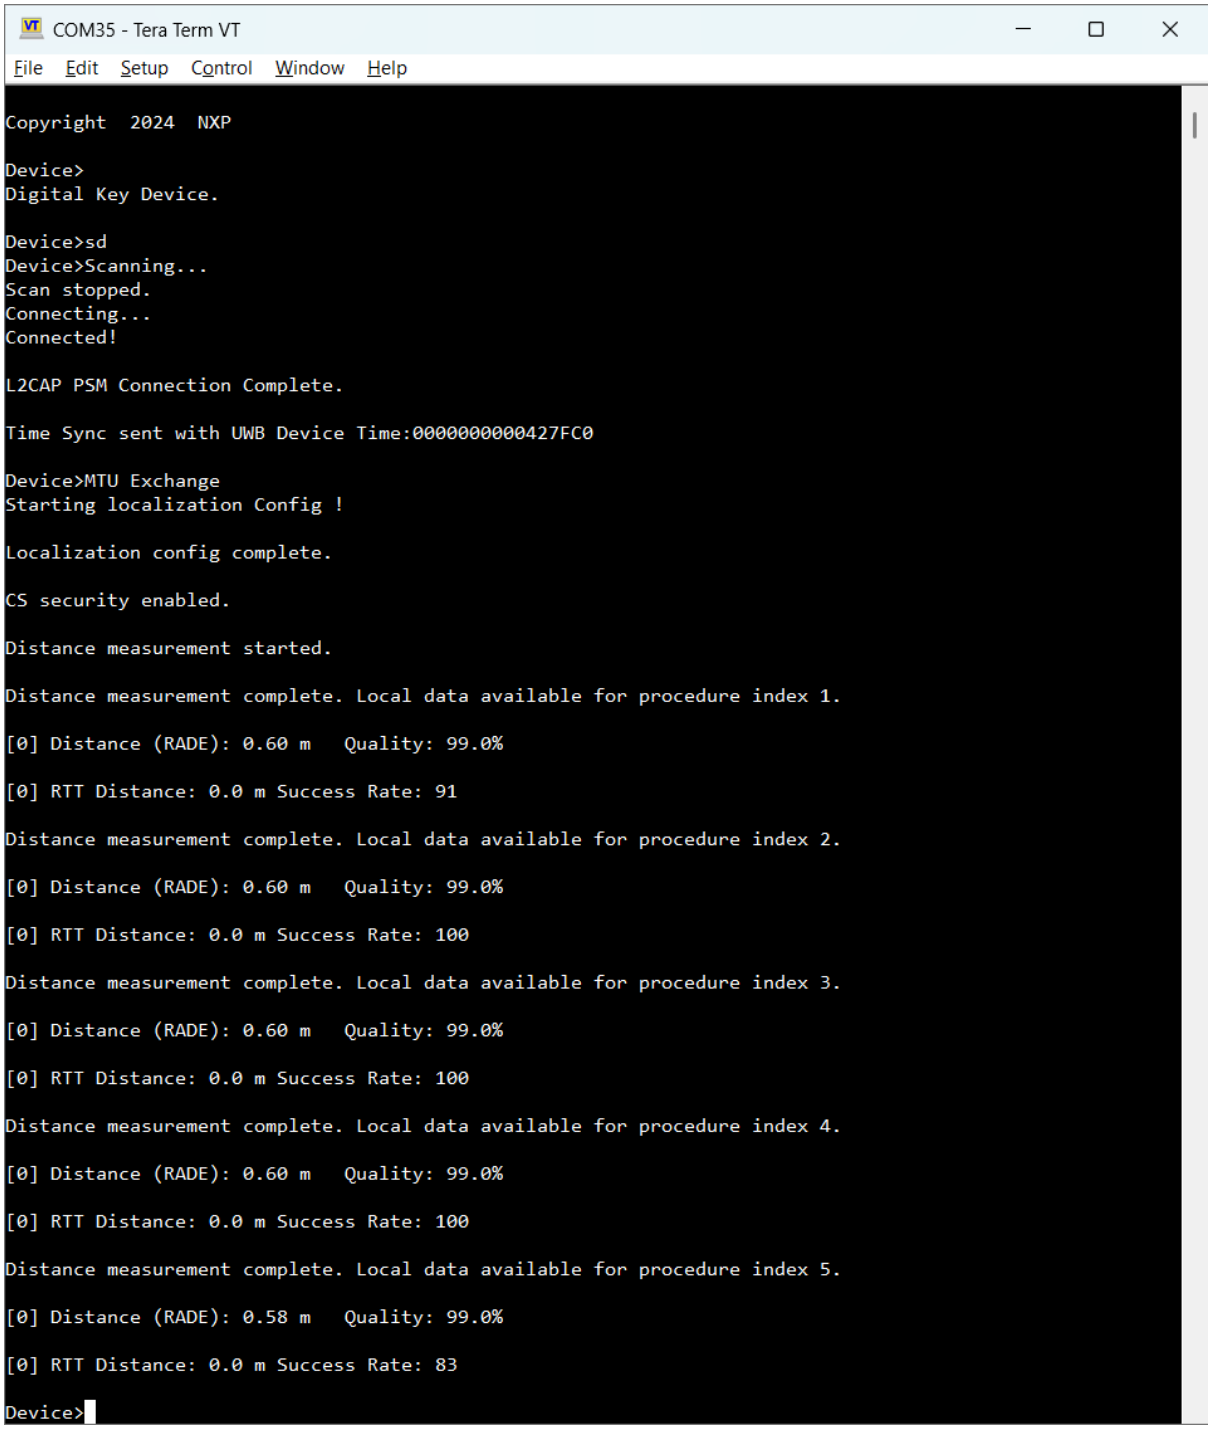
BTCS L2CAP data transfer



The CCC introduced the Bluetooth LE Channel Sounding (BTCS) measurement transfer feature. BTCS procedures are configured and executed using the Bluetooth Low Energy connection established for the Digital Key Service. The results of the BTCS procedures are transferred to the vehicle and used to estimate the distance. The data transfer is done through the L2CAP channel created during the passive entry scenario. The format of the data transferred through BTCS is defined by the CCC. The algorithms used on the receiver to estimate the distance are (RADE and CDE).

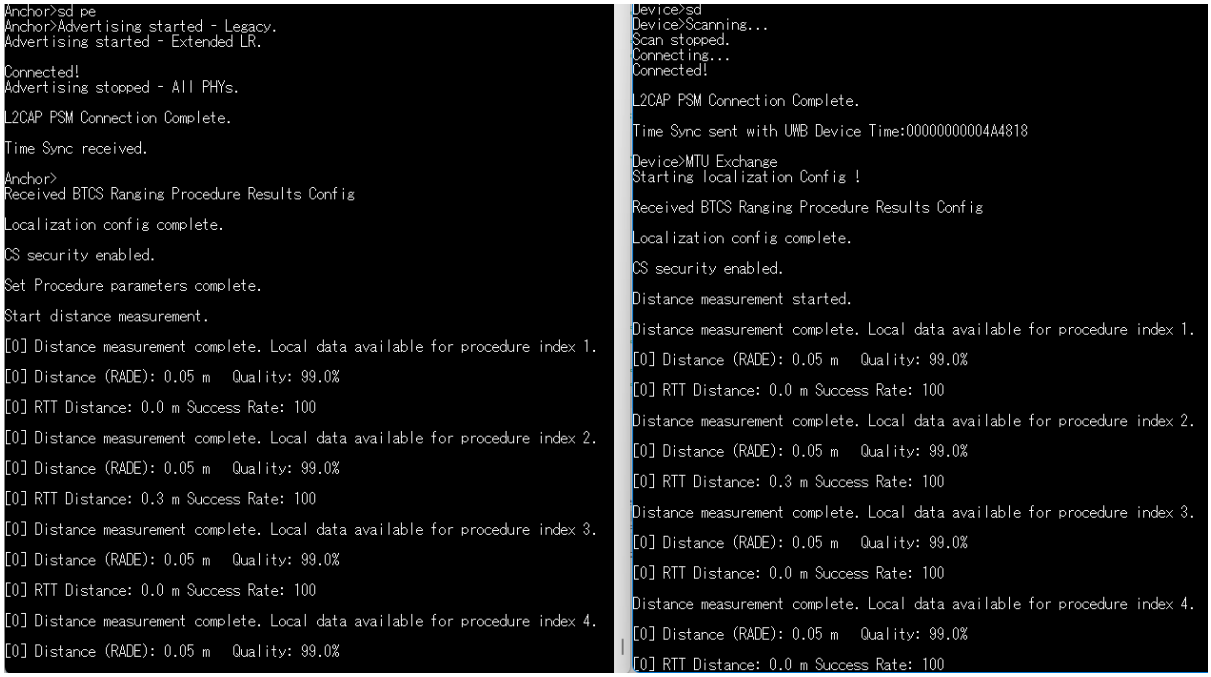
The default transfer direction enabled in the digital_key_car_anchor_cs and digital_key_device_cs is from Device to the Anchor. To reverse the transfer direction in BTCS, the following defines must be set in the app_preinclude.h file:

- digital_key_car_anchor_cs: gAppBtcsClient_d set to 0 and gAppBtcsServer_d set to 1
- digital_key_device_cs: gAppBtcsServer_d set to 0 and gAppBtcsClient_d set to 1



The figure below shows the car Anchor output after BTCS transfer direction is reversed.

BTCS transfer - car Anchor output



The figure below shows the Device output after BTCS is enabled.

BTCS transfer - Device output

Both digital_key_car_anchor_cs and digital_key_device_cs applications support gAppBtcsClient_d and gAppBtcsServer_d configuration options at the same time. Also, the algorithm can be run on both (gAppRunAlgo_d can be set on both applicaitons at the same time). Here is a picture showing both applications running the algorithm.

BTCS L2CAP transfer watchdog (NXP proprietary extension)

The CCC BTCS specification does not define any timeout for the L2CAP measurement transfer. As an NXP proprietary extension, the BTCS client provides a watchdog timer that prevents the CS procedure auto-restart loop from stalling when a BTCS L2CAP transfer is lost or never completes. The watchdog is client-side only and is always enabled. Its duration in seconds is configured through gBtcsTimeoutSeconds_c (default 3). The timer is armed when the client starts waiting for the peer transfer and is stopped as soon as the transfer completes. If it expires, the loop is only restarted once the full procedure sequence (maxNumProcedures) has been reached; otherwise the client just returns to waiting for the next procedure's measurement data.

Parent topic:*Localization scenarios*

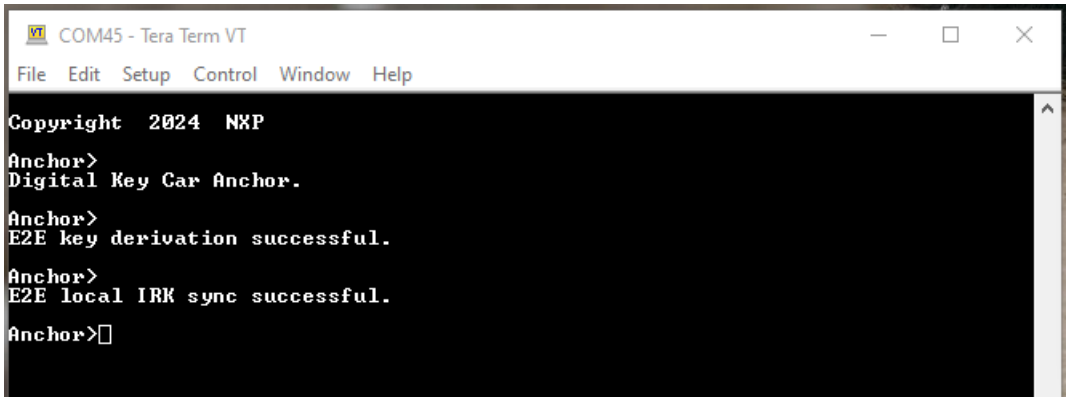
Running the A2B scenario

The A2B feature allows for the secure transfer of Bluetooth Low Energy security keys information between the Car Anchor devices. The feature is supported on the following platforms:

- KW47-EVK with a life cycle state of OEM-Open or higher, this feature is provided by th EdgeLock Secure Enclave.
- FRDM-KW43 with a life cycle state of OEM-Open or higher, this feature is provided by the EdgeLock Secure Enclave.

The Car Anchor demo application makes use of the A2B feature to securely synchronize the local Identity Resolving Key (IRK) and the Bonding Data (LTK Long Term Key and peer IRK) with another Car Anchor.

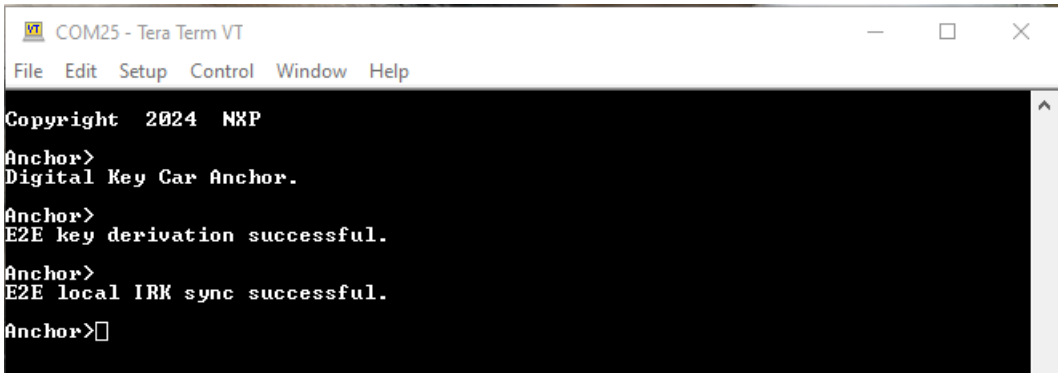
Prerequisites:



- Three boards (two act as Car Anchors, one as a Device). The demo is currently limited to a maximum of two Car Anchors.
- The two Car Anchors must be connected via a serial interface as described in the section above.
- Advanced Secure Mode must be enabled. The following macros must be defined and set to 1 in *app_preinclude.h* for the ***digital_key_car_anchor_cs*** project:
  - gAppSecureMode_d
  - gA2BEnabled_d

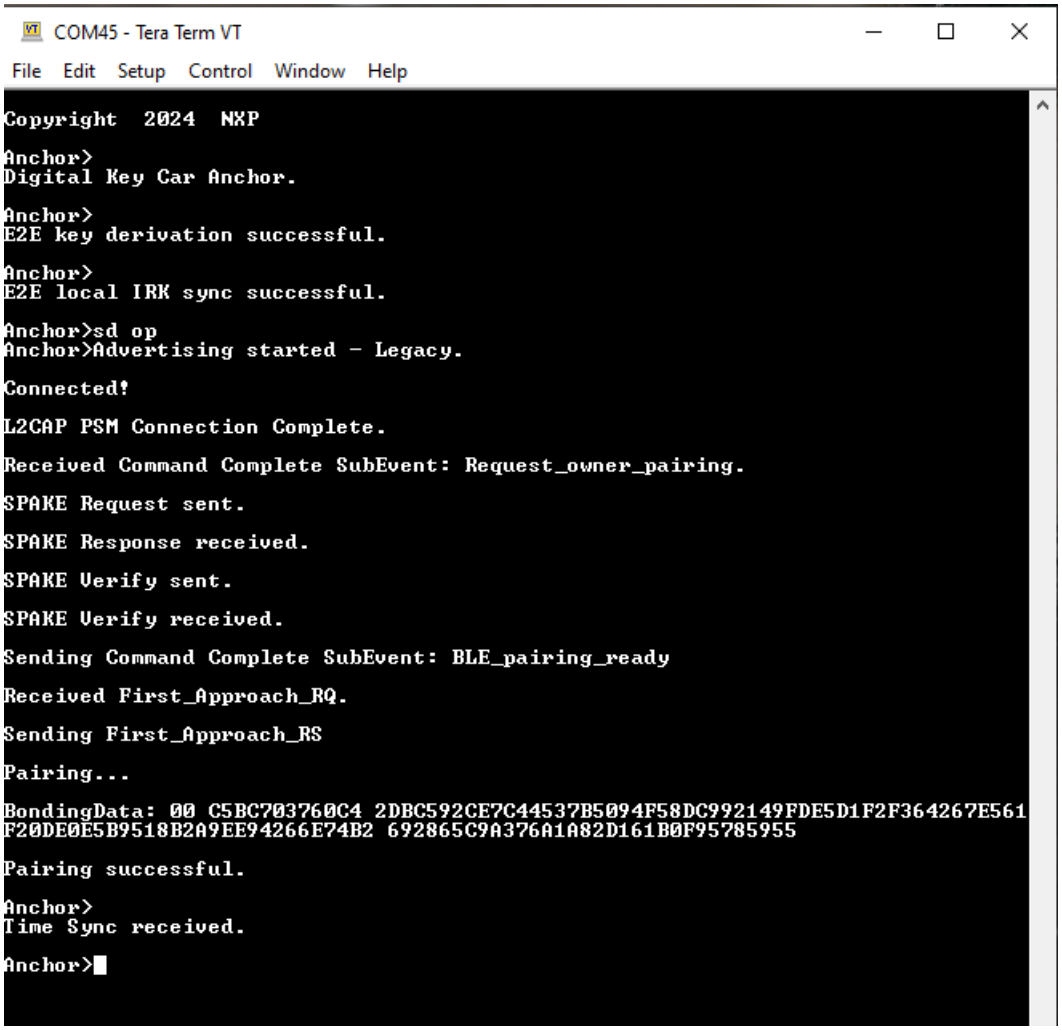
- One of the Car Anchors must be configured with the *gA2BInitiator_d* macro set to 1, this is called Car Anchor A, and the other must be configured with the *gA2BInitiator_d* macro set to 0, called Car Anchor B. Car Anchor A triggers the EdgeLock-to-EdgeLock (E2E) key derivation and local IRK synchronization. Therefore, it should be started up after Car Anchor B.

Demo steps:



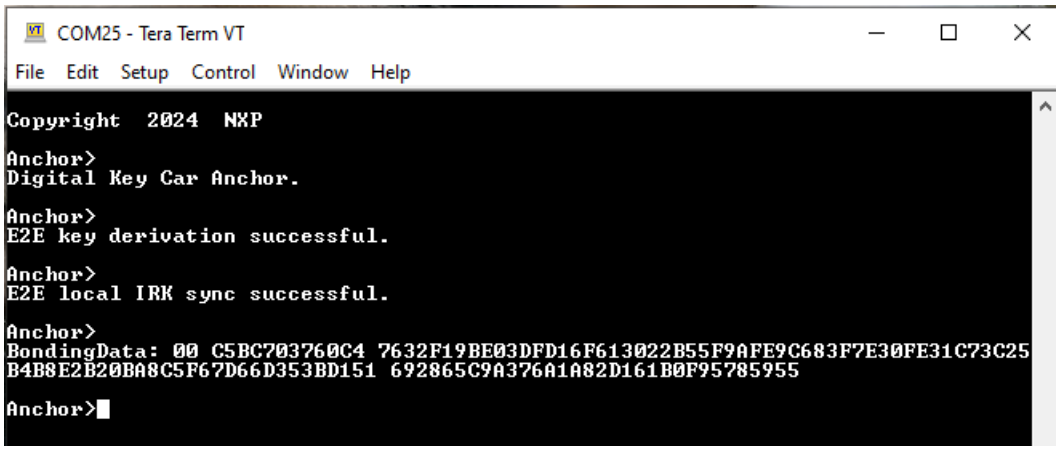
- Start Car Anchor B, then Car Anchor A. At initialization the E2E key is derived and the local IRK of Car Anchor A is sent as a secure blob to Car Anchor B in order for both Car Anchors to have the same local IRK. This process is shown in the figure below.

Car Anchor A starts up, derives the E2E key and syncs with Car Anchor B



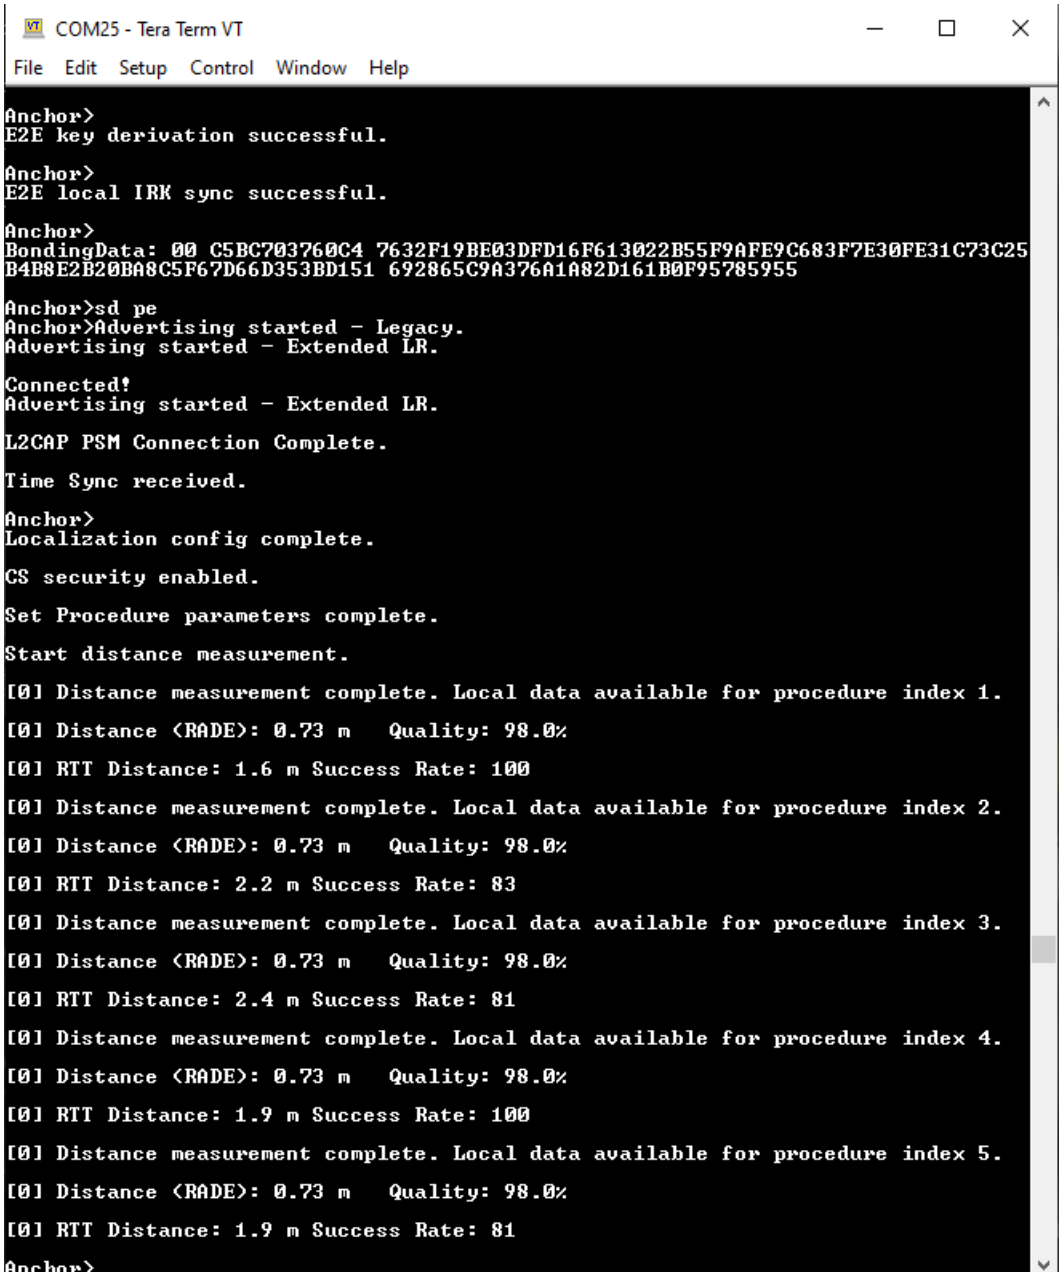
- The below figure shows the Car Anchor B starting up and syncing with Car Anchor A.

Car Anchor B starts up and syncs with Car Anchor A



- Trigger the Owner Pairing scenario by sending the "sd" command on the Device and "sd op" on Car Anchor A. Once the bond is created, the Bonding Data containing secured blobs for the LTK and peer IRK is sent to Car Anchor B. The Car Anchors print the Bonding Data in shell with the LTK in blob form (the LTK is never available in plain text) and the peer IRK in plain text. Now both Car Anchors have the same Bonding Data. The figure below shows that the Car Anchor A pairs with the Device.

Car Anchor A pairs with Device



The figure below shows that the Car Anchor B receives the Bonding Data via the serial interface.

Car Anchor B has received the Bonding Data via the serial interface

- Disconnect Car Anchor A by sending the `dcnt` command.
- Once Car Anchor A is disconnected, run the `sd` command on the Device and run the `sd pe` command on Car Anchor B. Car Anchor B is now able to perform a Passive Entry connection, without pairing. The below figure shows the process.

Car Anchor B performs Passive Entry without pairing

Low-power mode

The CCC Owner Pairing and Passive Entry scenarios (with Channel Sounding support) can also run in Low-power mode. This feature is supported on the following platforms:

- KW47-EVK
- KW47-LOC
- KW43-LOC
- FRDM-KW43

To enable Low-power mode, set the gAppLowpowerEnabled_d macro to 1 in the app_preinclude.h file for the **digital_key_car_anchor_cs** and/or the **digital_key_device_cs** projects.

In Low-power mode, the shell interface is not available. Interaction with the demos is done through buttons. The button configuration is the same for all supported platforms.

The below table lists the buttons applicable for the car Anchor.

Car Anchor buttons

Button	Press	Description
SW2	(short press)	Starts Owner Pairing ADV
SW3	(long press)	Starts Passive Entry ADV

The below table lists the buttons applicable for the Device.

Device buttons

Button	Press	Description
SW2	(short press)	Starts Scanning

Acronyms and abbreviations

The following table lists the acronyms that have been used in this document.

Abbreviation	Description
Bluetooth LE	Bluetooth Low Energy
BTCS	Bluetooth LE Channel Sounding
CAN	Controller Area Network
CCC	Car Connectivity Consortium
CR	Change Request
CS	Channel Sounding
CDE	Complex-domain Distance Estimation
E2E	EdgeLock-to-EdgeLock
HCI	Host Controller Interface
IRK	Identity Resolving Key
L2CAP	Logical Link Control and Adaptation Protocol
LTK	Long Term Key
OOB	Out-of-Band
RADE	Rapid Accurate Distance Estimator
RSSI	Received Signal Strength Indicator
SDK	Software Development Kit
UWB	Ultra-Wideband

Revision history

The table below summarizes the revisions to this document.

Document ID	Release date	Description
AN13979 v.2.2	06 April 2026	- Added support for FRDM-KW43 platform. See *CCC Digital Key hardware platforms*

- Added the FRDM-KW43 platform in documentation.

|AN13979 v.2.1|18 March 2025|- Added support for KW47-LOC platform. See *CCC Digital Key hardware platforms*

- Added the sections Exporting HCI data and BTCS L2CAP data transfer.
- Other updates.

| |AN13979 v.2.0|26 November 2024|- Added support for KW47-EVK platform. See *CCC Digital Key hardware platforms*

- Updated for KW47 EAR 2.1 release

| |AN13979 v.1.3|June 2024|Updated for SDK 2.16.000| |AN13979 v.1.2|25 January 2024|Updated for MR4Added Running the Packet Monitoring scenario and *Low-power mode*

| |AN13979 v.1.1|16 October 2023|Initial release for MR3- Added Running the Anchor Monitoring scenario

- Modified *Running the Connection Handover scenario*

| |AN13979 v.1.0|23 June 2023|Initial release for MR2|

CS Wireless Ranging Demo Application User Guide Introduction

The application presented in this document relies on channel sounding (CS) Bluetooth Low Energy implementation as defined by the Bluetooth Special Interest Group (SIG).

CS protocol performs secure and highly accurate distance estimation between two Bluetooth Low Energy devices. CS supports two different measurement modes: RTT and RTP. RTP is used for an accurate distance estimation and RTT to get a coarse but secure distance bound.

For more details about CS techniques, see *Bluetooth Channel Sounding Technique for Distance Estimation* (document AN13481).

The application relies on LE_CS_Create_Config, LE_CS_Set_Procedure_Parameters, and LE_CS_Set_Procedure_Enable HCI commands to perform CS measurements. CS measurement results are sent through host controller interface (HCI) using LE_CS_Subevent_Result_Continue and LE_CS_Subevent_Result_Continue HCI events. They are centralized on the client board by the wireless ranging application to be combined and passed to various distance computation algorithms, being embedded, or PC-based.

See Acronyms for details on which part of the standard is supported.

Wireless ranging application allows to:

- Configure most of the parameters required for a CS measurement (number of steps, type of steps, CS channels, CS timings (T_FCS, T_IP, T_PM), and so on)
- Select what type of measurement to be performed (RTT, RTP, or both) based on configured CS step modes (1 or 2)
- Initiate CS setup phase (exchange of capabilities, configuration, and so on)
- Trigger CS measurements
- Retrieve CS measurement results (RTP, RTT, and other debug information) from peer device over Bluetooth Low Energy connection
- Compute distance estimations by combining RTT and RTP measurements from both devices
- Log system debug information but also raw IQ data information in Matlab (*.mat), Excel (*.xls), or numpy (*.npz) format that can be used for further analysis or development of distance computation algorithms

Wireless ranging application is made of two parts:

- Embedded firmware that can be controlled manually via a serial connection
- Host application (Python) running on a PC and controlling the firmware using a serial link

The embedded firmware is in charge of:

- Initiate CS setup (CS capabilities, CS security)
- Handling CS configuration and measurement requests from the host application
- Synchronizing initiator and reflector devices
- Scheduling and executing CS measurements over the air
- Generate pseudo random sequences for channels, AAs, and so on, using CS DRBG
- Collecting measurement results from one device to the other
- Send back CS measurement results to the host application
- Perform distance computation using embedded algorithms (namely CDE and RADE)

While the host application:

- Automates measurement requests
- Logs measurement results in output files

- Performs two ways channel reconstruction from captured PCT data and runs the high-resolution phase-based ranging algorithm (RADE)

Requirements

This chapter provides information about hardware and software requirements.

Hardware and software requirements

For information on hardware setup and how to build and flash an application using the toolchain of your choice, see the *Getting Started Guide* for your selected board.

CS wireless ranging demo application is designed to run on KW47-EVK, KW47-LOC, KW43-LOC, MCX-W72-EVK, MCXW72-LOC, FRDM-MCXW72 and FRDM-KW43 platforms, referred to as “board” in the rest of this document.

Parent topic:*Requirements*

Toolchain requirements

WR demo application was compiled and tested with IAR Embedded Workbench and Visual Studio Code. Employing one of these IDEs is recommended.

Parent topic:*Requirements*

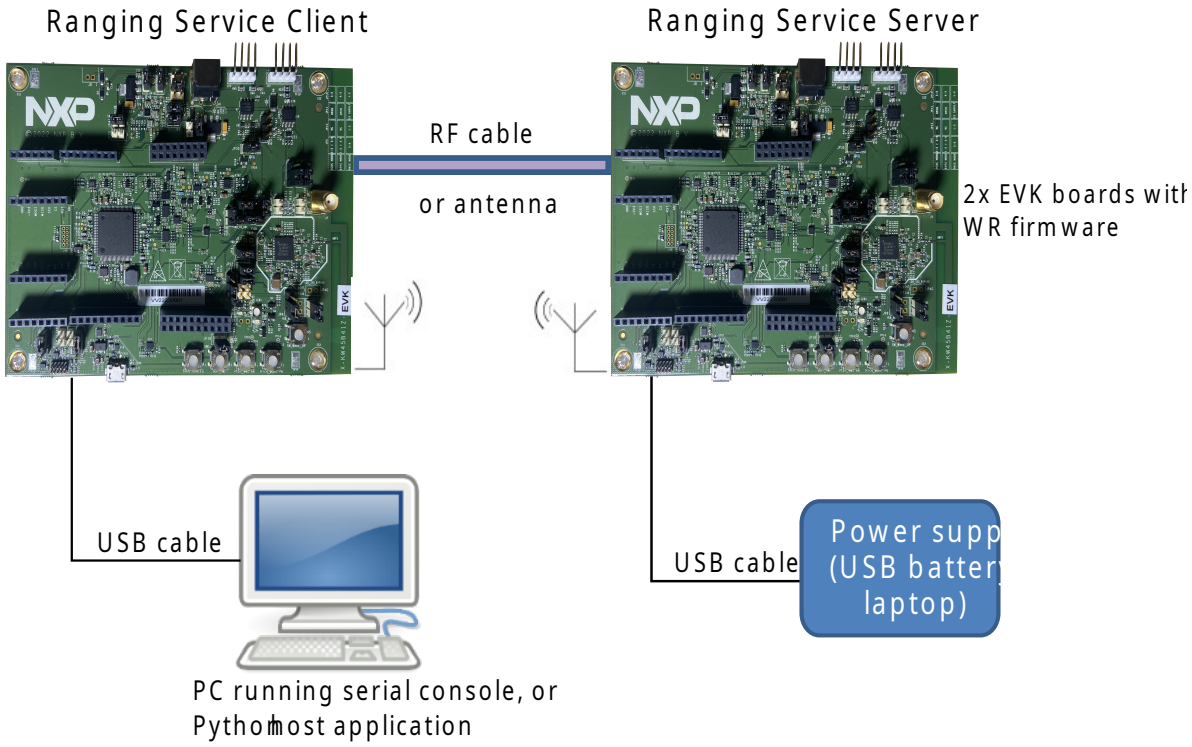
Wireless ranging demo application setup

This chapter provides information about hardware and software setup.

Hardware set up with single antenna configuration

Prerequisites

- Two boards (ranging service client and ranging service server)
- PC



The first board (ranging service client) should be connected to the PC running the host application (see Python host application setup) using a USB cable. Once flashed, the second board (ranging service server), may be connected to a USB battery to facilitate movement.

Start the evaluation of this ranging system with a cabled configuration. Once the system operation is properly understood, the evaluation can be pursued in more challenging environments (with multi-path and interference).

To perform cabled measurements with KW47 boards, a small hardware modification must be done on the PCB. Rotate a capacitor to bypass the printed antenna and connect the RF path to an external SMA connector.

For further details, refer to the documentation corresponding to your board of choice. To perform radiated testing, connect an SMA-mounted antenna on each board instead of a cable.

Figure: Typical wireless ranging setup using KW47-EVK boards

Parent topic:*Wireless ranging demo application setup*

Hardware set up with antenna diversity

To enable antenna diversity on KW47-EVK boards, antenna diversity boards (X-FR-ANTDV-IFA or X-FR-ANTDV-MPIFA) must be plugged to the EVKs using a similar setup as described in Hardware set up with single antenna configuration. The X-FR-ANTDV-IFA is a preferred option. Currently, only the X-FR-ANTDV-IFA is being distributed to the customers.

For a detailed setup description, see *Antenna Diversity Board User's Guide* (document ADBUG). **Figure: Antenna diversity board mounted on KW45 EVK board**

From antenna diversity boards, you must choose the pair of antennas, either the two SMA con-

nectors or the two printed antennas, to be used.

Another convenient way to enable antenna diversity testing is to use the KW47-LOC or KW43-LOC board which embeds two printed antennas on the same PCB. For a detailed description of these boards and how to set them up, refer to the *KW47-LOC Board User Manual* or the *KW43-LOC Board User Manual*.

To configure antenna diversity properly in the firmware, it is required to configure the following:

- Antenna diversity board type and antennas used (SMA connectors or printed antennas)
- Antenna configuration index
- Antenna switching time (T_SW)

Note: All platforms support only 1x1 or 2x2 antenna configurations, leading to either one or four antenna paths being used.

Parent topic:*Wireless ranging demo application setup*

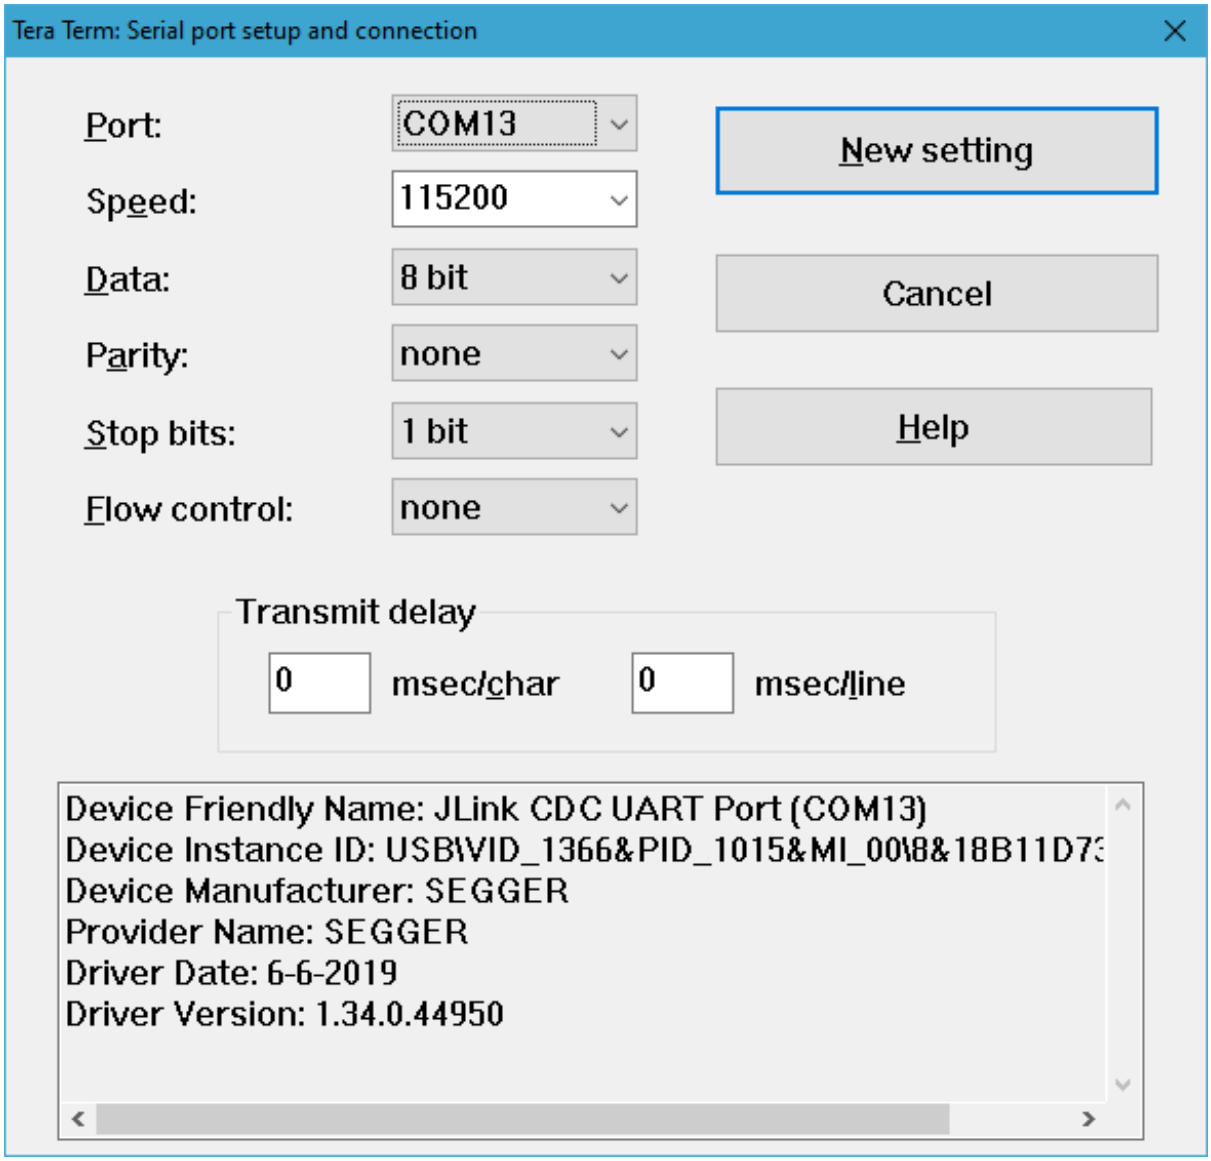
Firmware setup

To install the firmware on the boards, perform the steps below:

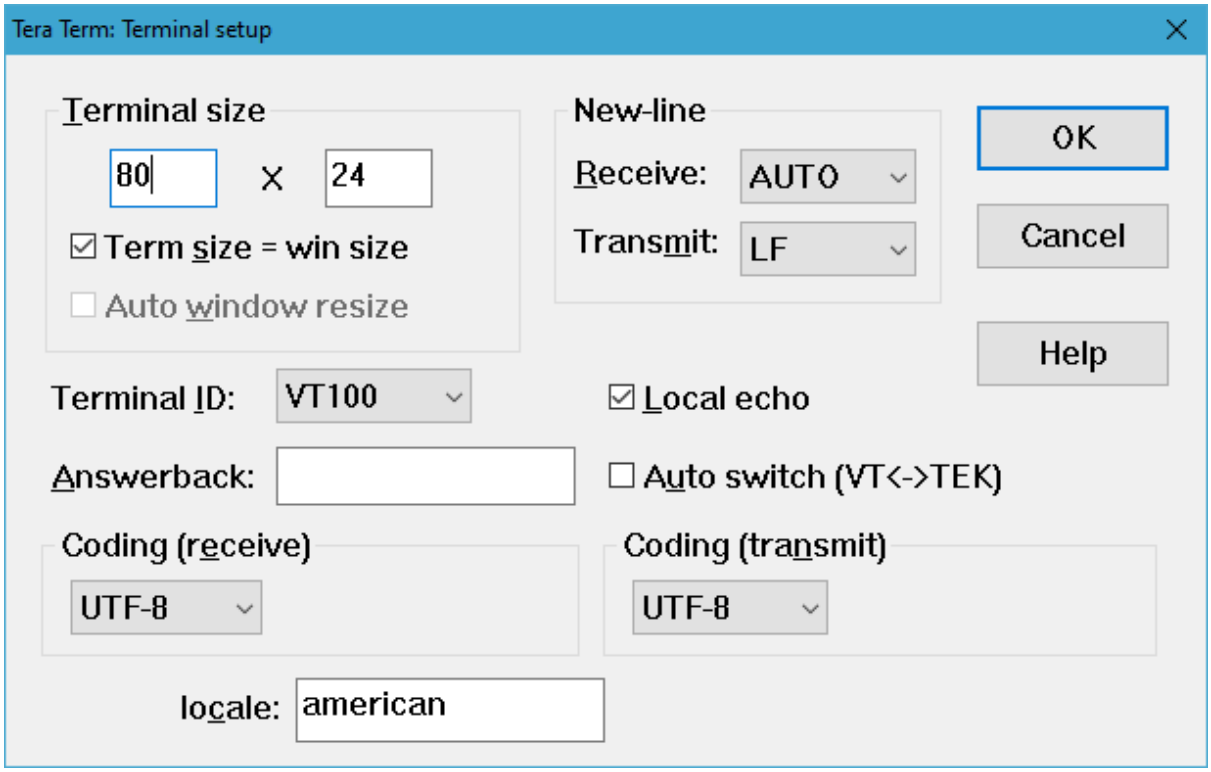
Note: The firmware must be installed on the two boards following those two steps.

1. Update your NBU image with the provided binaries in the following folder of the SDK: ../middleware/wireless/ble_controller/bin (*_hadm_* for KW45 family).
2. Compile the application wireless_ranging_bluetooth_bm by referring to the quick start guide specific to your platform. The application can be found in the directory:

   \\boards\<board>\wireless_examples\bluetooth\wireless_ranging
3. Flash the binary on both devices. Flash the application using your preferred IDE.



Parent topic:*Wireless ranging demo application setup*



Serial console setup

Wireless ranging application can be used either by using a console or by using a Python script environment. To use the console, connect to each device COM port with Tera Term using the setup (putty is not supported), as shown in the figure below.

Python host application setup

To use the Python host application, go to tools\lcl_host. This folder is referred later in the document as <app_folder>.

This application is a Python application which requires several packages and Python 3.12 or newer. The supported OS is Windows. It has not been tested on other Python-capable OS.

The recommended approach is to install the required packages inside a Python virtual environment. This keeps the packages isolated from your system-wide Python installation and avoids conflicts with existing packages.

The list of required packages is provided in <app_folder>\python\requirements.txt. The same packages are also listed in <app_folder>\python\Pipfile.

To use the Python host application, follow the steps below:

Note: The following installation procedure is provided for Windows. Use Windows command prompt to execute commands below.

1. Install Python 3.12 or newer for 64-bit platform.

   Note: The "python" executable must point to Python 3.12 or newer (use python -V to check the version).

2. Go to the <app_folder>/python folder and create a virtual environment.

   ```
   cd <app_folder>/python
   python -m venv .venv
   ```

3. Activate the virtual environment.

   ```
   source .venv\Scripts\activate
   ```

   After activation, the command prompt is prefixed with (.venv).

4. Install the required packages inside the virtual environment.

```
pip install -r requirements.txt
```

This command may take several minutes to complete.

When you are done, you can leave the virtual environment by running deactivate. Remember to activate the virtual environment again (step 3) before running the host application in a new terminal session.

Parent topic:*Wireless ranging demo application setup*

Running wireless ranging demo application

This chapter provides information on how to run wireless application.

Using the console

Choose this option if you want to perform simple non-automated measurements without invoking any ranging algorithm.

If you want to run hosted algorithms or automated series of measurements, the host application is a better choice. See the following chapters for more detail.

Configuring the ranging service client

Connect to the board that acts as the ranging service client (the board that initiates the measurement request) using a serial console (see Firmware setup).

Run the following command:

```
communication role {central | peripheral}
```

Parent topic: Using the console

Triggering one CS measurement

First, ensure that you have configured the ranging service server and ranging service client boards as described above.

To trigger a measurement, run the following command:

```
range
```

Both devices synchronize to each other and perform a CS test procedure using default settings.

The expected output is a JSON-like structure similar to the following:

```
items:[{mciq:{cfg:{n_ap:1,n_stp:79},result:{vf:79,cde:8.76,cqi:1.000},},tof:{cfg:{n_stp:13},result:{ad:7.8,
↪sr:100},},},]
CRC32:cf49a670
marker:[DONE]
```

If verbosity is increased, the output may contain numerous additional information. It may contain all CS results output as well as debug information.

See section Command response for how to interpret these results.

Parent topic: Using the console

Changing CS configuration

The console configures numerous CS parameters.

See *Embedded firmware command reference* for the exhaustive firmware configuration commands that can be passed through the command line interface (CLI).

Parent topic: Using the console

Parent topic:*Running wireless ranging demo application*

Using Python host application

Using Python application to trigger CS measurements is the preferred option. It takes care of automatically interpreting the CS results, passing them into the selected algorithm, and presenting the output in user-friendly formats.

At this stage, we assume that the setup is properly connected and firmware and host application have been properly installed and configured.

Note: Be sure that you have configured the ranging service server board as Bluetooth Low Energy peripheral, as described above.

The application is in the form of a Python script located in: <app_folder>\python\Scripts\record_range_measurement.py.

To check that everything is installed properly, enter:

```
python record_range_measurement.py --help
```

It should display command usage. If any Python issue shows up, revisit the installation section.

Application parameters

The --help option provides most of the explanation regarding command-line options.

See additional information below:

- The application attempts to detect boards automatically. However, it is possible to force which COM port to connect to using --comport option.
- By default, the application attempts to detect two boards: one acts as a client, and another one acts as the server. Using -R option allows you to run the application with a single board (client) connected to the PC. Once the client is configured, it can be moved freely without being connected to the PC, as shown in the figure.
- The client always acts as the Bluetooth Low Energy central role. Additionally, by default, the client acts as the CS initiator (CS role can be changed using --role option).
- The application prints results on the screen. However, using --target option (can be specified multiple times), it is also possible to generate output files in the following formats:
  - Text file (*.txt) that contains only the raw data exchanged between firmware and Python script.
  - Numpy format (*.npz) that can be loaded using Python numpy library. It contains both raw data and results of distance estimations.
  - Matlab format (*.mat) that can be loaded directly into Matlab. It contains both raw data and results of distance estimations.
  - CSV file (*.csv) that contains distance estimation results dumped for each measurement.

Parent topic: Using Python host application

Performing CS measurements with only step mode 2's

The following command triggers a series of 5 CS measurements using RTP:

```
python record_range_measurement.py --mainmode 2 -n 5
```

The above command uses default CS parameters configured in the firmware.

To change some parameters, --dutconfig arguments can be added to the command.

For example to select 2 Mbit/s PHY, use:

```
--dutconfig "param rtt_phy 1"
```

To enable antenna diversity 2x2 with SMA connectors from antenna diversity board, use:

```
--dutconfig "param ant 7" --dutconfig "param ant_type 1" --dutconfig "param timings t_sw 2"
```

See *Embedded firmware command reference* for the exhaustive firmware configuration commands that can be passed through the --dutconfig option.

The output of the script shows:

- Several miscellaneous information, such as serial ports used, configuration, and so on:

```
2024-12-04 10:44:40 [INFO] ___main___: Working on win32
2024-12-04 10:44:40 [INFO] ranging_platform_pkg.utils: Configuring RangingPlatform_kw45 as peer on port:␣
↪COM26 with unique_id: 0x000000000000
2024-12-04 10:44:41 [INFO] ranging_platform_pkg.utils: Configuring RangingPlatform_kw45 as dut on port:␣
↪COM27 with unique_id: 0x000000000000
2024-12-04 10:44:43 [INFO] ranging_platform_pkg.utils: Starting measurement with 1 parameters and 5␣
↪measurements
2024-12-04 10:44:43 [INFO] ranging_platform_pkg.utils: COM27:    central initiator
```

- A series of measurements returning estimated distance, initiator RSSI, reflector RSSI, and measurement duration:
- Measurements statistics (average and standard deviation):

```
==========Measurement stats ==========
Results for board pair (1, 1):
RTP: avg=0.29, stdev=0.00, min=0.29, max=0.29
RADE: avg=0.29, stdev=0.00, min=0.29, max=0.29
==========
```

Depending on the --target option selected, different output files are generated in <app_folder>\python\Scripts\records\ folder.

Parent topic: Using Python host application

Performing distance estimation using mode 2's as main mode and mode 1 as submode

The following command triggers a series of 5 CS measurements using RTP/RTT:

```
python record_range_measurement.py --mainmode 2 --submode 1 -n5
```

Expected output is as follows where SRDE and RTT distance are computed:

```
2021-11-18 09:49:05 [INFO] record_range_measurement:␣
↪==========
2021-11-18 09:49:05 [INFO] ranging_platform_pkg.utils: - parameter0 - meas_nr has 5 values
2021-11-18 09:49:05 [INFO] ranging_platform_pkg.utils: Iteration -    0/5    @(meas_nr = 00) => RTP/RTT-
↪distance = 12.47m/13.56m (100%), RSSI = -33dBm/-47dBm, Duration = 335ms
```

Parent topic: Using Python host application

Configuring embedded algorithms

The following command triggers CS measurements using the embedded CDE + RADE algorithms and RTP/RTT with minimal verbosity output:

```
python record_range_measurement.py --mainmode 2 --submode 1 --algo 0,5
```

```
2024-12-04 11:03:51 [INFO] ___main___: Working on win32

Embedded firmware command reference

This chapter provides details about CLI commands supported by the firmware.

Firmware shell commands

The firmware can be controlled with a shell accessible using the serial terminal. This chapter describes the command-line interface to secure proximity devices along with common command syntax and response format.

Note: The shell does not show any prompt.

Parent topic:*Embedded firmware command reference*

Command syntax

The command line interface (CLI) is text-based, that is, only printable characters are used. The user can interact with the board using some commands such as a regular command prompt. This process requires a serial terminal application such as Tera Term/Putty. Line processes commands, that is, all information needed to process a command is contained in one line. Lines are terminated with the "line-feed" character. A command consists of one or more space separated words where each word, except the first, can be a command, submenu, or value (of any type; integer/hex/character/string). The first word cannot be a value. All commands are constructed with menus, which consist of commands and/or submenus. Commands can have zero or more value arguments.

Implicit commands

The command-line processor has two implicit commands:

- "help" or if no <name> is specified – this command shows all available commands/submenus in the selected menu.
- "show" – this command shows the current values of all readable items in the selected menu.

Parent topic: Command syntax

Command response

The device does not echo back the commands given to it. However, the device can respond to each command received immediately and with a single line, except the "range", "help", and "show" commands. The "range" commands also have a delayed response.

The response for single-line commands is "<last-subcommand>: <value>". All responses are terminated with one "line-feed" character.

Parent topic: Command syntax

Boot message

When the device boots, it displays the following information:

- Software version number of the application
- Git hash and build date
- The reset reason of the device, for example, PIN, SW, WATCHOG

Parent topic: Command syntax

Parent topic:*Embedded firmware command reference*

Main menu

By sending the “help” command, a help menu gets listed (see below). Commands are provided to initiate a ranging measurement, display, and modify parameters.

```
----------commands----------
range [<ble-address>] | Run HADM procedure measurement with given peer
test [<tx,rx>] | Run HADM test mode measurement
setup [<ble-address>] | Run HADM setup (from Central only)
communication [options] | Communication commands
parameter [options] | Parameter commands
system [options] | System commands
misc [options] | Miscellaneous commands
----------end----------
```

The options displayed are explained in the table below:

Table: Wireless ranging top level commands

Command	Description
range	Execute a CS measurement using the Bluetooth Low Energy connection (implicitly set service role of the board as “client”). Limitation: should be issued from the same board after first invocation
test	Execute a CS measurement using CS test either as initiator (TX) or reflector (RX)
parameter	Submenu to set/display CS parameters
communication	Set Bluetooth Low Energy role (central/peripheral)
system	Submenu to set/display system-related parameters
misc	Submenu to set/display miscellaneous parameters

“parameter” - CS parameters

The *CS parameters menu* lists and allows modification of CS configuration. The options displayed here are explained in the table below.

```
----------commands----------
ch_list | Channel list commands (test mode only)
ch_map [<bitmask> [<repeat>]] | Set/show channel map as 10 hexa octets (79 bits used)
cs_algo [<0|1> [<0|1>] [<2...8>]] | Set/show channel selection algo type (0=3b, 1=3c), and for #3c: shape␣
↪(0=hat, 1=X) and jump
```

(continues on next page)

(continued from previous page)

```
main_mode_nb [<1...160> <1...160> <0...3>] | Set/show numbers of HADM main mode steps (min, max,␣
↪repetition)
mode0_nb [<1...3>] | Set/show number of HADM mode0 steps
mode_type [<1...3> [<1...3>]] | Set/show main mode and sub-mode types
role [<initiator,reflector>] | Set/show HADM role
rtt_phy [<0|1>] | Set/show RTT phy rate (0=1Mbps, 1=2Mbps)
tx_pwr [<-12...MAX>] | Set/show TX power in dBm of CS measurement. Range is -12dBm to max chip␣
↪capability
debug [<0-255>] | Set/show debug options (REPORT_DBG_INFO<2>, IQ_AVERAGE_DISABLE<1>,␣
↪IQ_DETAILS<0>)
ant_cfg [<0|7> [<0...23|255>]] | Set/show antenna config index and (test mode only) permutation index
ant_type [<0-5> ] | Set/show antenna board type: 0:none, 1:X-FR-ANTDIV SMA, 2:X-FR-ANTDIV printed,␣
↪3:LOC SMA, 4:LOC printed, 5:LOC printed SMA1 dummy
pn_seq [<AA initiator> [<AA reflector>]] | Set/show PN sequences (must be a hex number, test mode only)
tone_ext [<0...4>] | Set/show TP tone extension (test mode only)
timings | Timings commands
----------end----------
```

Table: Wireless ranging CS parameters commands

Command	Default	Description
ch_list	-	Used to define the CS channel list in test mode
ch_map	All ones	Used to define the CS channel map in connected modeUse “param ch_map 0x1FFFFFFFFFFFC7FFFFC” to mask advertising channels
cs_algo	0	Used to define channel selection algorithm type (0=3b, 1=3c), and for #3c: shape (0=hat, 1=X) and jump
main_m	4, 4, 0	Numbers of CS main mode steps (min, max, repetition)
mode0_	2	Set/show numbers of CS mode 0 steps
mode_t	2,1	Set/show main mode and submode types as defined by CS**Note that the step mode 3 is only supported on KW47 and KW43 platforms.**
role	Initiator	Set/show CS role
rtt_phy	0	Set/show RTT PHY rate (0=1 Mbit/s, 1=2 Mbit/s)
tx_pwr	0	TX power in dBm used during the CS measurement;[-12...10] dBm
pn_seq	-	Set/show the PN sequences to be used in test mode
tone_ex	-	Set/show the tone extension behavior in test mode
timings	-	Timings submenu (see below); Only for test mode
debug	0	For internal debug purpose
ant_cfg	0, 0	Antenna configuration index as defined in CS specs (0:1x1, 7:2x2) followed by a permutation index (0-23 for fixed permutation index and 255 for rolling over all permutation indexes)
ant_typ	0	Antenna diversity board to be used (0:None, 1: X-FR-ANTDIV SMA connectors, 2: X-FR-ANTDIV printed antennas, 3: LOC SMA, 4: LOC printed, 5: LOC printed + SMA1 for dummy antenna)

“ch_list” parameter

The “ch_list” command parameter defines the CS channel list. It only applies in test mode. See for example, the code below:

```
set [<0...78>,..,<0...78> [<repeat>]] | Set/show channel list
generate <0...78> <0...78> [rand] | Generate channel list from first and last CS channels
```

Two modes can be used:

- The “set” mode to input a CS channel list that is input to the firmware.

```
parameter ch_list set 0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16
```

  This mode defines a CS sequence of 17 steps on CS channels in the given order.

- The “generate” mode makes the firmware generate the channel list based on a start and stop frequency.

```
parameter ch_list generate 0 78
```

  This mode defines a CS sequence of 79 steps on CS channels 0 to 78 (linear sweep). This is the default behavior of the firmware.

There is also a possibility to randomize the generated frequency list.

```
parameter ch_list generate 0 78 rand
```

It defines a CS sequence of 79 steps on CS channels 0 to 78 in a pseudo-randomized order.

Parent topic:”parameter” - CS parameters

“timings” – CS timings configuration

```
----------commands----------
intervals <150|80|50> <145|80|40> [<145|80|40> ] | Set/show HADM interval timings T_FCS, T_IP1, T_
↪IP2 (us)
t_pm <20|40> | Set/show HADM T_PM timing (us)
t_sw <2|4|10> | Set/show HADM T_SW timing (us)
----------end----------
```

Table: Wireless ranging CS timings commands

Command	Default	Description
intervals	150, 145, 145 (test mode)50, 40, 40 (connected)	Set T_FCS, T_IP1 and T_IP2 interval in µs, as defined by CS. Allowed values are: 150 µs, 80 µs, and 50 µs for T_FCS and 145 µs, 80 µs, and 40 µs for T_IP1 and T_IP2.
t_pm	20	Set T_PM, duration in µs, as defined by CS Allowed values are: 20 µs and 40 µs
t_sw	0	When antenna diversity is used, this command controls the antenna switch time which can be set to 2 µs, 4 µs, or 10 µs. Otherwise 0 is used.

Note: The ‘Timings’ input is relevant for test mode only. In connected mode, the BLE controller chooses timings based on CS capability exchanged between the two devices. NXP controller implementation chooses the fastest timings supported by the two devices.

Parent topic:”parameter” - CS parameters

Parent topic: Main menu

“system” – system commands

```
----------commands----------
build_info | Show SW build information
debug [0|1] | Enable debug features (DTEST...)
verbosity [<0...255>] | Set/show verbosity flags (1=Info, 2=Debug, 4=MeasurementInfo, 8=MeasurementData,
↪ 16=MeasurementDebug, 32=BoardInfo, 64=Profiling)
```

(continues on next page)

(continued from previous page)

```
unique_id | Show Unique Id
version | Show SW version number
reset | Reset MCU
store | Store all parameters
factory | Reload and store factory defaults
events | Show events
timing | Show BLE timing
baudrate <value> | Set/show baudrate of serial interface (default: 115200, volatile)
output_format | Show output format
calibrate [<MCIQ dist> <ToF dist> [store]] | Set/Show zero-distance calibration, distances are in meters, Q10
----------end----------
```

Table. Wireless ranging system commands

Command	Default	Comment
verbosity	13	Level of details of the range response in the form of bits field. Add verbosity flag values to combine them (for instance 12 for Measurement Info and Measurement Data).
unique_	NA	6 bytes unique identifier. Reserved for future use; all zeros for now
version	NA	Application version. For example: v2.0.0
build_in	NA	Build version information (Git hash, and so on)
reset	NA	Reset the CPU
store	NA	Save settings to flash
factory	NA	Revert to default settings
events	NA	Reserved for future use
timing	NA	Reserved for future use
baudrate	1152	Change the baud rate of the UART interface. This setting is volatile, that is, it is restored to the default value after a power cycle or reset.
output_forı	4	Internal usage

Parent topic: Main menu

"misc" – miscellaneous commands

```
----------commands----------
xtal_trim [<0...63>] | Set/show XTAL trim value
cw_trim [0|1] | Start/Stop 2440MHz constant wave Tx (used for XTAL trimming)
rtp_algo [<0...7>] | Set/show RTP embedded algorithm bitmap to be run (bit0:CDE, bit2:RADE)
rtp_algo_config [<1(CDE)> [<param1> <param2>]] | Set/show RTP embedded algorithm configuration
```

Table: Wireless ranging miscellaneous commands

Com-mand	De-fault	Comment
xtal_trir	0	Set/show 32 MHz crystal oscillator trimming value. Combined with cw_trim command, it allows you to adjust Xtal precisely.
cw_trim	-	Turn on/off a 2440 MHz constant wave transmission to tune the Xtal (using xtal_trim)
rtp_algc	1	Set RTP embedded algorithm to be run in bitmap format: 0: No embedded algorithm is runbit 0: The firmware runs the CDE algorithm bit 2: The firmware runs the RADE algorithm
rtp_algc	-	This command can be used to customize some parameters of CDE algorithm. It is for internal usage only.

Firmware response interpretation

Each CS measurement produces results represented as a JSON-like structure terminated with "[DONE]".

The "system verbosity" command controls the verbosity of the output.

An example response of a "range" command with default (minimal) verbosity, showing mainly the distance computation results ('cde' and 'ad' fields in meters), without any additional data is shown below:

```
items:[{mciq:{cfg:{n_ap:4,n_stp:79},result:{vf:79,cde:0.64,cqi:0.842},},tof:{cfg:{n_stp:13},result:{ad:0.3,
↪sr:100},},},]
CRC32:1cebcbcb
marker:[DONE]
```

An example response of a "range" command is shown below:

```
items:[{hadm:{cfg:{rtyp:0,rphy:0,txpwr:0,fcs:150,ip1:145,ip2:145,tpm:20,ant:0},

These responses have an albeit slightly modified YAML syntax. The modifications are: ": " is replaced with ":" and indentation/end-of-lines are removed by using the YAML data stream syntax. This reduces the output size to a minimum.

Online YAML beautifier tools can be used (after adding a space after double-colons) to convert them into a more readable format.

The above example is shown below:

```

At the top level, we have the *items*, *profiling*, and *marker* elements. The marker element is there to signal the end of the message.

The profiling element contains timing related information about the CS procedure.

The items element is a list of *range-result* blocks. The parameters in range-result block are shown in the table below.

Table. Wireless ranging response structure

Hierarchy	Parameter	Unit	Description
Init/refl	u	-	Unique ID of board (required)
Init/refl	v	-	SW Version (required)
CS configuration			
hadm	sts	-	CS event status (0 = OK)
hadm.cfg	rtyp	-	CS rtt_type configured
hadm.cfg	rphy	-	CS rtt_phy configured
hadm.cfg	fcs	µs	CS T_FCS configured
hadm.cfg	ip1/ip2	µs	CS T_IP1/T_IP2 configured
hadm.cfg	tpm	µs	CS T_PM configured
CS steps configuration			
hadm.stp	nb	#	Number of steps of CS event
hadm.stp	md	#	Step mode array of the CS event (0-3)
hadm.stp	ch	#	Channel number mode array of the CS event (0-79)
CS mode 0 config and results			
hadm.stp	evt	#	CS subevent event index (2 hex digits per CS subever
hadm.stp	se	#	Last CS step index of each CS subevent (2 hex digits p
hadm.md0.cfg	n_stp	#	Number of mode 0 steps
hadm.md0.init/refl	r	dBm	Mode 0 RSSI array of n_stp steps
hadm.md0.init/refl	c	Hz	Mode 0 CFO array of n_stp steps
MCIQ (RTP) results			
mciq.cfg	n_ap	#	Number of antenna paths for RTP (<=4)
mciq.cfg	n_stp	#	Number of steps containing PCTs (step modes 2 and

Table 48 – cont

Hierarchy	Parameter	Unit	Description
mciq.init/refl	i	-	List of base64 encoded 12 bit PCT I values, that is, fo
mciq.init/refl	q	-	List of base64 encoded 12-bit PCT Q values, that is, fo
mciq.init/refl	tqi	-	List of TQI values for each tone; Repeated per anten
mciq.result	cde, cqi	m, #	CDE distance estimation and quality indicator comp

mciq.result	rade, rade_dqi	m, #	RADE distance estimation and quality indicator com
ToF (RTT) results			
tof.cfg	n_stp	#	Number of steps containing RTT packets (step mode
tof.init/refl	d	ns	List of base64 encoded 18 bits + 4 error bits ToA-ToD
tof.init/refl	r	dBm	Mode 1 or 3 packet RSSI array (required, length=n_s
tof.result	ad, sr	m, %	Average distance estimation and success rate as com
tof.init/refl	| nadm	| - |	Estimated chance of an attack on the received packe
CS measurement info			
info.init/refl	syn	#	Mode 0 index in sequence that was used to synchron
info.init/refl	syg	#	AGC index used during whole CS event (<= 11)
info.init/refl	syr	dBm	RSSI of mode 0 used for gain lock
info.init/refl	syc	Hz	CFO of mode 0 used for CFO compensation
info.init/refl	f	-	Error/warning flag (see description below)
info.init/refl	te	-	Reserved for future use

The table below shows the “info” error flags bit field description.

Table: Info error flags interpretation

Bit Mask	Comment
0x0001	PLL lock error
0x0002	CS sequence was aborted
0x0004	Error during AGC lock
0x0008	Error during IQ capture
0x0010	RSSI measured became too low
0x0020	Error happened during Mode 0 synchronization phase
0x0040	Timestamp reading on one or more RTT packets failed
0x0080	SW scheduler detected a desynchronization with RSM HW scheduler
0x0100	XCVR API reported an error

Use the script record_range_measurement.py to decode this data and obtain numerical values. We do not provide the encoding method of the compressed fields here.

Table: CSV fields description

Field	Description
meta.error_msg	Application error message.
meta.testcase.meas_nr	Ranging measurement number.
mciq.cfg.n_ap	Number of antenna paths used during CS mode 2 or mode 3 steps. Typically 1 for
mciq.cfg.n_stp	Number of CS RTP steps (mode2 or mode3) included in the CS procedure.
mciq.result.CDE_distance	CDE distance estimate in meters.
mciq.result.CDE_dqi	CDE distance quality indicator between 0 and 1.
mciq.result.RADE	RADE distance estimate in meters.
mciq.result.RADE_dqi	RADE distance quality indicator between 0 and 1.
mciq.result.RADE_error	RADE error status.
mciq.result.distance	Distance estimate in meters.
mciq.result.slope_rmse	IQ samples quality metric in degree. 2-way phase slope root mean square error.
tof.cfg.n_stp	Number of CS RTT steps (mode1 or mode3) included in the CS procedure.

Table 49 – continued from previ

Field	Description
tof.result.distance	RTT distance estimate in meters.
tof.result.successrate	How many CS RTT packets were sucessfully exchanged during the CS procedure, i
tof.result.init_nadm	Initiator Normalized Attack Detector Metric.
tof.result.refl_nadm	Reflector Normalized Attack Detector Metric.
tof.result.std	Standard deviation of the distance computed over all CS mode 1 steps.
md0.cfg.n_stp	Number of CS mode 0 steps (Synchronization) included in the CS procedure.
hadm.cfg.rtyp	Channel sounding RTT Type.
hadm.cfg.rphy	Channel sounding RTT PHY (0 = 1Mbps, 1 = 2Mbps).
hadm.cfg.txpwr	TX power used during the CS procedure, in dBm.
hadm.cfg.fcs	Channel sounding T_FCS, in µs. Frequency change period.
hadm.cfg.ip1	Channel sounding T_IP1, in µs. Defined for the CS mode 0 and CS mode 1 : idle tim

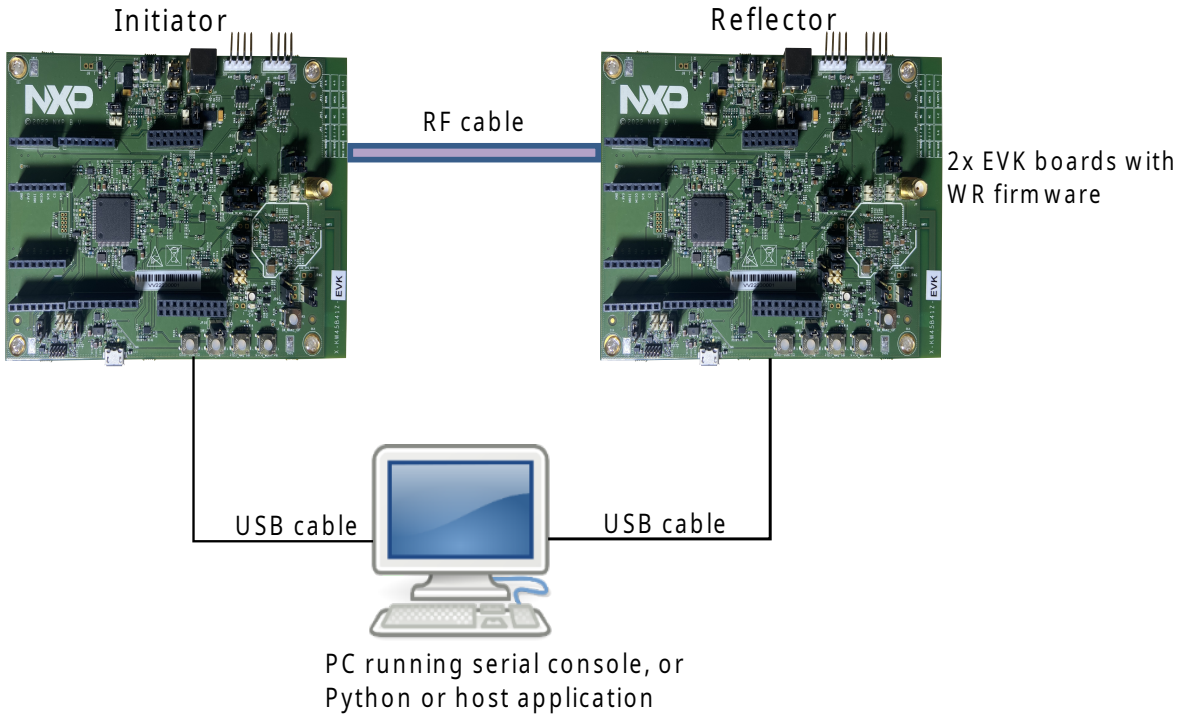
Appendices



This chapter provides some additional information about the following: - Test mode hardware setup and operation- Wireless ranging and channel sounding standardization.

Test mode

There is an alternate way to test CS feature that does not require a BLE connection to be established between the boards. This is called "test mode", and it relies on the LE_CS_Test HCI command from the standard.

Hardware setup

This mode requires that both boards are connected to the controller PC to collect and combine data from both initiator and reflector.

Parent topic: Test mode

Operating test mode

This chapter provides information on how to use wireless application in test mode.

Using Python host application

When using test mode from Python host application, the following parameter must be added to the command:

```
--testmode
```

Parent topic: Operating test mode

Using the console

To start the measurement on the reflector side:

```
\> test rx
```

To start the measurement on the initiator side:

```
\> test tx
```

Both devices synchronize to each other and perform a CS test procedure using default settings.

The expected output (on both devices) is a JSON-like structure similar to the following:

```
items:[{hadm:{cfg:{rtyp:0,rphy:0,txpwr:0,fcs:150,ip1:145,ip2:145,tpm:20,ant:7},sts:0,stp:{nb:101,md:

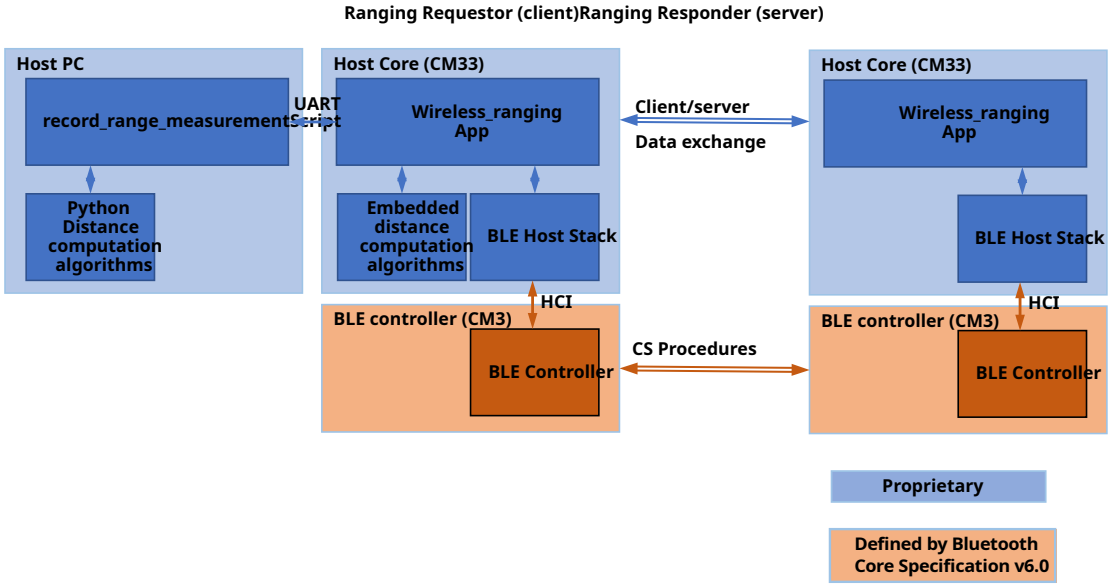
Wireless ranging and channel sounding standardization

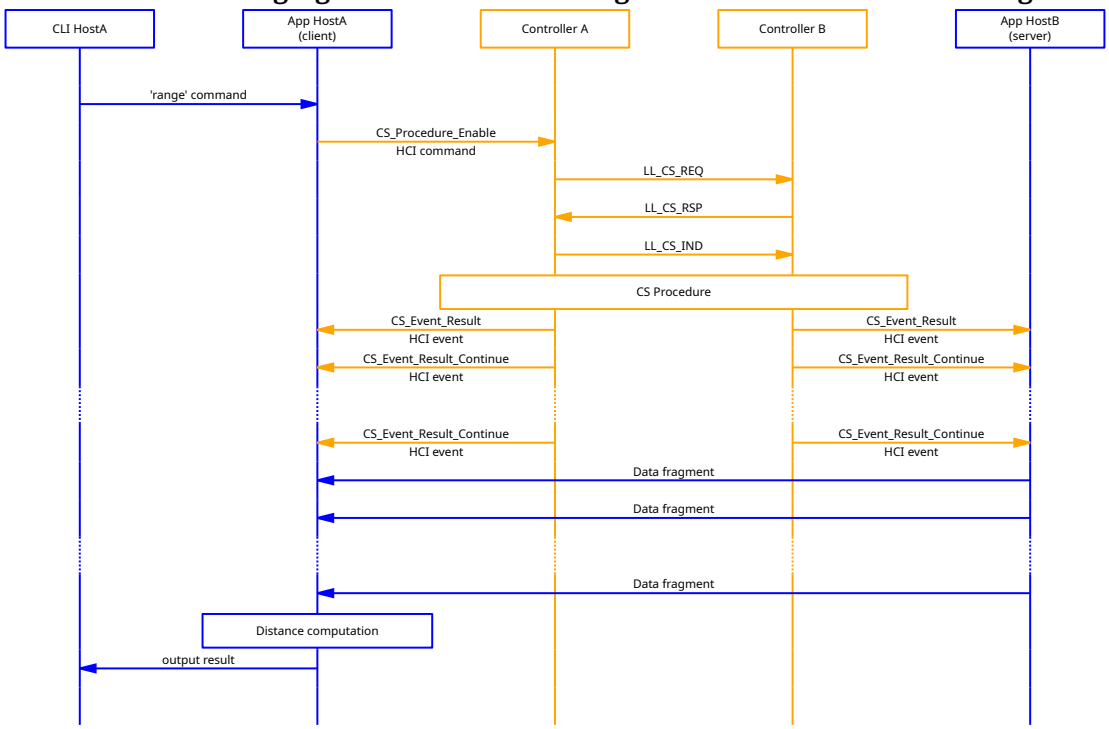
In this chapter, we are highlighting which part of wireless ranging application complies with a standard and which one does not.



The Bluetooth Low Energy SIG defines two standards:

- Channel sounding is defined by the core working group. It defines the behavior of the Bluetooth Low Energy controller and how to interface it for CS features. The specification covers how the CS feature must be implemented in a Bluetooth Low Energy controller.
- Ranging service and profile (RASP) is defined by the “Direction Finding” working group. It defines an architecture (client/server) and a Bluetooth Low Energy profile for applications that require to operate Channel Sounding feature.

The Bluetooth Low Energy SIG *does not* define any sort of distance computation method. Wireless ranging application provides two sample algorithms to demonstrate the full ranging concept. The first is CDE, an embedded implementation with low complexity. The second one is RADE, which provides an essential compromise between complexity and performance. As mentioned previously, wireless ranging Python framework ensures that a user can develop their own signal processing algorithm using the real IQ datasets.



Wireless ranging is based on channel sounding core specifications, as mentioned in the associated SDK release note. It does not implement RASP specification. The figure below shows the application architecture with a colored overlay of what is defined by the standards.

Figure: Wireless ranging software architecture and channel sounding overlay

Similarly, the figure below shows a sequence chart highlighting a single measurement sequencing with colored overlay. The steps defined by the standard are highlighted in orange.

Figure: Wireless ranging software flow diagram and channel sounding overlay

Acronyms

The table below lists the terms and acronyms used in this document.

Term	Definition
Measurement bias	Constant offset observed between estimated distance and real distance
Central/Peripheral	Refer to BLE connection roles – the central must be connected to a PC
Initiator	Device initiating the measurement and collecting data
Reflector	Device responding to the initiator during measurement phase
Multi channel IQ (MCIQ)	Method to capture IQ samples of data exchanged between two devices on multiple channels separated by a fixed increment
Time of flight (ToF)	Method to capture round-trip time between two devices and estimate distance based on speed of light
Complex-domain distance estimation (CDE)	Phase-based distance estimation algorithm
Multiple signal classification (MUSIC)	Phase-based distance estimation super-resolution algorithm
RTT	Round-trip time
RTP	Round-trip phase; synonym for MCIQ
HADM	High accuracy distance measurement
CS	New name for HADM
AGC	Automatic gain control
CFO	Carrier frequency offset
RSSI	Receive signal strength indicator
PCT	Phase correction term (I&Q)
WR	Wireless ranging application
RADE	Rapid and accurate distance estimation

Revision history

The table below summarizes the revisions to this document.

Revision number	Date	Substantive changes
2.2	22 July 2025	Removed KW45 platforms support
2.1	10 April 2025	Converted to Markdown format
2.0	13 January 2025	Updated for MCUXpresso SDK 24.12.00 release
1	26 June 2023	Updated multiple sections for KW45 MR2 SDK
0	10 October 2022	Initial release

Wireless Framework

Wireless Connectivity Framework Connectivity Framework repository provides both connectivity platform enablement with hardware abstraction layer and a set of Services for NXP connectivity stacks : BLE, Zigbee, OpenThread, Matter.

The connectivity framework repository consists of:

- Common folder to common header files for minimal type definition to be used in the repo
- Platform folder used for platform enablement with Hardware abstraction:
  - platform/include: common API header files used by several platforms
  - platform/common: common code for several platforms
  - specifics platform folders , See below the supported platform list
  - platform/../configs folder: configuration files for framework repository and other middlewares (rpmsg, mbedTls, etc.._)
- Services folder
- Zephyr folder for zephyr modules integrated in mcux SDK
- clang formatting script and script folder to format appropriately the source files of the repo

Supported platforms

The following devices/platforms are supported in platform folder for connectivity applications:

- kw45x, k32w1x, mcxw71x, under wireless_mcu, kw45_k32w1_mcxw71 folders.
- kw47x, mcxw72x families under wireless_mcu, kw47_mcxw72, kw47_mcxw72_nbu folders.
- rw61x
- RT1060 and RT1170 for Matter
- Other RT devices such as i.MX RT595s

Supported services

The supported services are provided for connectivity stacks and their demo application, and are usually dependent on PLATFORM API implementation:

- DBG: Light Debug Module, currently a stubbed header file
- FSCI: Framework Serial Communication Interface between BLE host stack and upper layer located on an other core/device
- FunctionLib: wrapper to toolchain memory manipulation functions (memcpy, memcmp, etc) or use its own implementation for code size reduction
- HWParameters: Store Factory hardware parameters and Application parameters in Flash or IFR
- LowPower: wrapper of SDK power manager for connectivity applications
- ModuleInfo: Store and handle connectivity component versions
- NVM: NXP proprietary File System used for KW45, KW47 automotive devices and RT1060/RT1170 platform for Matter
- OtaSupport: Handle OTA binary writes into internal or external flash.
- SecLib and RNG: Crypto and Random Number generator functions. It supports several ports:
  - Software algorithms
  - Secure subsystem interface to an HW enclave
  - MbedTls 2.x interface
- Sensors: Provides service for Battery and temperature measurements
- SFC: Smart Frequency Calibration to be run from KW47/MCXW71 from NBU core. Matter related modules:
- OTW: Over The Wire module for External Transceiver firmware update from RT platforms
- FactoryDataProvider to be used for Matter

Supported Zephyr modules integration in mcux SDK

Connectivity framework provides integration and port layers to the following Zephyr Modules located into zephyr/subsys:

- NVS: Zephyr File System used by Matter and Zigbee
- Settings: Over layer module that allows to store keys into NVS File System used by Matter Port layer and required libraries for these zephyr modules are located in port and lib folder in zephyr directory

Connectivity framework CHANGELOG 7.4.3 mcux SDK 26.09.00 RFP

Major Changes

- [platform][DBG] Moved the NBU software watchdog (handcheck based NBU stuck detection) into the common platform_dbg sources, making the feature available on both KW43/MCXW70 and KW47/MCXW72 without additional files.

Minor Changes

- [wireless_mcu][wireless_nbu][kw43_mcxw70] Moved P256 public key generation and ECDH DH key computation from the NBU controller to the host. Added two ICS message types (ReadP256PublicKey/GenerateDHKey) with their host and NBU handlers, the new PLATFORM_ReadLocalP256PublicKey() and PLATFORM_GenerateDHKey() APIs, and the new gPlatformIcsDeferDHKeyToHost_d feature flag gating all host side DH key code. APIs are kept but empty when the flag is disabled so callers can keep the call unconditional. Also fixed the duplicate ICS enum sentinel gFwkSrvNbu2HostLast_c. gPlatformIcsDeferDHKeyToHost_d is disabled by default on the host to avoid pulling SecLib and the deferred DH key path into all applications; applications requiring this feature (e.g. hci_bb controller qualification) must explicitly build with -DgPlatformIcsDeferDHKeyToHost_d=1. The NBU configuration is unchanged and an assert catches the host/NBU misconfiguration in debug builds.
- [platform][zephyr] Zephyr feature flag overrides are now owned by the framework repo in a per platform configs/fwk_config_zephyr.h, included at the top of fwk_config.h under __ZEPHYR__, removing the dual maintenance with the Zephyr integration. MCUXSDK defaults and package content are unchanged. Platforms: kw43_mcxw70, kw45_k32w1_mcxw71, kw47_mcxw72, mcxw23, rw61x.
- [wireless_mcu][kw43_mcxw70] Added gPlatformNbuDebugGpioDAccessEnabled_d support on kw43_mcxw70 to grant the NBU access to all GPIOs managed by GPIOD, through the new PLATFORM_InitNbuSpecific() API performing the NBU platform specific initialization.
- [DBG] The NBU debug path now preserves the first fault/assert information: NBUDBG_StateCheck() no longer consumes the NBU debug state before a consumer callback is registered, the sys_debug_panic_triggered guard is hoisted in the hard fault handler so capture, host indication and coredump only run for the first fault, and only the first fault/assert is recorded through the new NBUDBG_RECORD_CLAIMED() macro.
- [KW43-LOC][lcl] Updated PLATFORM_InitLcl() to support antenna diversity on the KW43-LOC board.
- [NVS] Replaced memcpy() by HAL_FlashRead() for internal flash reads so that HAL checks and Async Flash mode synchronization are not bypassed.
- [kw43_mcxw70] SecLib_psa_config.h is now only added to the build when the PSA SecLib port is selected, aligned with kw45_k32w1_mcxw71 and kw47_mcxw72.
- [wireless_mcu] Added the missing fwk_config.h as first include in the kw43_mcxw70, kw45_k32w1_mcxw71 and kw47_mcxw72 platform files so that feature flag overrides are taken into account.
- [kw43_mcxw70] Removed the usage of the m_lowpower_flag_(start|size|end) linker symbols.

Bug Fixes

- [WorkQ] Increased the default FWK_SYSWORKQ_STACK_SIZE from 608 to 640 bytes to fix a stack overflow on the system work queue thread.
- [rw61x] Fixed RTOS heap exhaustion when initializing BLE several times (bt init/bt disable loops): the mutex is now created only once in PLATFORM_InitBle(), protected against TOCTOU with interrupt masking, the flag is reset in PLATFORM_TerminateBle() to allow re-creation after termination, and asserts are replaced by error code returns to remain correct in Release builds.

- [platform][TSTMR] Fixed the 56 bit version of the timestamp, now reading the TSTMR instance base and testing only the base pointer validity.
- [IW416][coex] Added the missing SD8978 firmware include guard in fwk_platform_coex.c, fixing the compilation error of IW416 coex_edgefast applications.
- [docs] Fixed Sphinx/docutils warnings and errors in the framework documentation: index title underline, leading transitions after README titles, and FSCI C code blocks that could not be lexed.
- [MISRA][CERT-C] Various MISRA, CERT-C and Coverity compliance fixes gathered across platform, LowPower, ICS (wireless_mcu and wireless_nbu), OTA, FSCI, SFC, SecLib and NVM modules: HCI packet length checks before field access, safe SWO prescaler computation, US_TO_TICK/PWR_ConvertUsecToTicks() saturation to TICK_TYPE_MAX, ICS message type re-validation in the Rx work handlers, OTA chunk length and CRC computation hardening, SFC unbalanced low power constraint release guard and 64 bit timestamp arithmetic, SecLib SHA-256 OVERRUN and padding fixes with AES block count overflow checks, NVM union initializer, plus in place annotations for the findings to be dismissed.
- [SFC] Prevent unnecessary SFA measurement retrieval when SFC is disabled. Added a check in the SFC ISR to verify that the SFC module is enabled before retrieving the SFA frequency measurement.

7.4.2 mcux SDK 26.09.00 pvw2

Major Changes

- [NVM] Refactored NVM handling to centralize address computation using offset-based flash access helpers (*_AtOffset) instead of stored flash addresses, reducing unsafe pointer arithmetic. NvUpdateSize() now returns uint16_t, added NV_PartitionBlankCheckAtOffset(), and deprecated NvIsMemoryAreaBlank(). Also fixed a data integrity issue in NvSaveAllDataSetEntry() and various Coverity/CERT-C findings.
- [platform] IFR BLE BD address is now reversed to match the BLE Host stack expectation. The PLATFORM_IFR_BD_ADDR_IS_MSB_FIRST option was removed with the reverse loop reworked accordingly.

Minor Changes

- [DBG] Added host-triggered NBU force fault for coredump capture through new PLATFORM_ForceNbuFault() and NBUDBG_ForceNbuFault() APIs, signaled to the NBU over MCMGR (MCMGR_REMOTE_APP_EVENT_COUNT set to 2 via Kconfig.defconfig for KW47/MCXW72).
- [DBG] Deferred the stall HCI event out of NBUDBG_StateCheck(), which now only sets the halted state and notifies the callback. Added new NBUDBG_SendStallEvent() API to emit the stall vendor event on demand.
- [DBG] Integrated Zephyr coredump capture into the app-core fault handler under CONFIG_DEBUG_COREDUMP.
- [kw43_mcxw70] Added PLATFORM_ReinitCrypto() function for low power support with PSA.
- [settings] Added IAR compiler support for iterable sections and disabled the SETTINGS_NAME_END IAR warning.
- [rw61x][zb] Backported hal_nxp patches using __ZEPHYR__ compile guards to disable dependencies not used in Zephyr.

Bug Fixes

- [wireless_mcu] Fixed FRO6M calibration by replacing FWK_MRCC_TSTMR0_CC/FWK_MRCC_TSTMR0 macros with MRCC_CC/MRCC_MUX from fsl_clock.h and preserving the MUX clock selection in PLATFORM_StartFro6MCalibration().
- [PSA] Fixed Kconfig warning by adding KW43 support in crypto Kconfig.
- [DBG] Guarded FreeRTOS sys_dump_callstack_ext() with INCLUDE_xTaskGetHandle to fix -Werror=unused-function build failures.
- [Coverity] Various Coverity compliance fixes in SecLib (DHKey handling in SecLib_GenerateBluetoothF5KeysSecure()) and OTA (replaced union with structure for callback/argument passing in message buffer).

7.4.1 mcux SDK 26.09.00 pvw1

Major Changes

- [SecLib_RNG] Enabled PSA by default on KW43/MCXW70 platforms.
- [OTA] Introduced gOtaEraseWholePartitionOnInit_d option (KW43 only, disabled by default) to erase the whole OTA partition at start of image transfer.
- [wireless_mcu] Replaced the critical section in PLATFORM_RemoteActiveReq() and PLATFORM_RemoteActiveRel() with a shared mutex to reduce critical section duration. **These APIs must not be called from ISR anymore.**
- [wireless_nbu] Updated the low power callback to check for pending RPMSG buffers so the NBU enters WFI only when a Tx message is pending, reducing main core latency.

Minor Changes

- [SecLib_RNG] Added to RNG_psa.c seed support including WorkQueue-based automatic reseeding gRngEnableAutoReseed_d, NBU seed forwarding via PLATFORM_SendRngSeed(), reseed counter logic gRngMaxRequests_d, and new APIs RNG_NotifyReseedNeeded() and RNG_IsReseedNeeded().
- [OTA] Added a blank check of the OTA partition to avoid unnecessary erase operations and refactored OTA_MakeHeadRoom().

Bug Fixes

- [zephyr][lib][crc] Fixed build conflict with EdgeFast OPN CRC by guarding CRC sources with the Zephyr common framework component check to avoid symbol redefinition.
- [NVM] Fixed offset validation in NvGetEntryFromDataPtr() and corrected the bottom record address calculation in NvGetPageFreeSpace() when gUnmirroredFeatureSet_d is undefined.

7.3.3 mcux SDK 26.06.00

New supported platform : kw43, mcxw70 (EAR: Engineering drop only)

Minor Changes

- [kw43_mcxw70][NVM] Added flash ECC option support for KW43 platforms.
- [kw45_k32w1_mcxw71][kw47_mcxw72] Removed use of SIRCCSR SDK definitions for wakeup by UART0.
- [platform] Added platform abstraction macros PLATFORM_GET_IPSR, PLATFORM_SET_INT_MASK, and PLATFORM_CLEAR_INT_MASK to allow platform-specific customization of IPSR read and interrupt mask functions while maintaining backward compatibility.

Bug Fixes

- [kw43_mcxw70] Enabled gPlatformUseHwParameter_d to prevent generation of a new Bluetooth device address at each reset.
- [kw43_mcxw70] Added gPlatformHasNbu_d compile flag to KW43 platform configuration to declare NBU domain presence.

7.3.2 mcux SDK 26.06.00 pvw2

Major Changes

- [NVM] Enhanced robustness of NVM MIT (Meta Information Tag) operations with improved validation and error handling. Added checksum validation feature controlled by gNvmMetaCheckSum_d compilation switch. Systematically validates MIT fields before use and triggers page switch if corruption detected. Fixed mNvTableSizeInFlash tracking when table entries are modified. Refactored NvWriteRecord() and added NvModuleSwitchPage() for better ECC fault handling. Added NvSetChecksumEnable() API to control feature at runtime. Feature disabled by default.

Minor Changes

- [wireless_mcu][ble] Refactored PLATFORM_SetBleMaxTxPower() API moved from platform file to fwk_platform_ble.c for Zephyr compatibility.
- [wireless_mcu] Modified PLATFORM_GetBDAddr() to return consistent address across calls when gPlatformUseHwParameter_d is disabled.
- [platform] Added FRDMKW43 to supported platform families.
- [Common] Enhanced external flash API with C++ compatibility by adding extern “C” guards.
- [kw43_mcxw70] Relocated PLATFORM_TM_CLK_SELECT macro to fwk_platform_definitions.h for platform-specific configuration.
- [kw43_mcxw70][sensors] Adapted temperature measurement to use FIFO0 instead of FIFO1 as only single FIFO available on this platform.
- [kw43_mcxw70] Updated framework component selections in configuration files.
- [wireless_nbu] Replaced FPGA_TARGET guard with FWK_KW43_MCXW70_NBU_FAMILIES for CPU clock configuration to better reflect target family.
- [kw43_mcxw70] Updated RF switch control and debug signal configurations for bringup support.
- [kw43_mcxw70] Hardware parameters placement switched to IFR mode. Compilation macro gHwParamsProdDataPlacement_c changed from gHwParamsProdDataMainFlash2IfrMode_c to gHwParamsProdDataIfrMode_c.
- [kw43_mcxw70_nbu] Enabled NBU Deep Sleep support. Removed PLATFORM_RemoteActiveReq() and PLATFORM_RemoteActiveRel() implementations as they are not required for this platform.
- [kw43_mcxw70] Enabled TRNG support on kw43_mcxw70 platform.
- [SecLib_RNG] Renamed TRNG_ISR to RNG_TrngIrqHandler() and mapped IRQ handler for platforms using TRNG to this implementation.

Bug Fixes

- [NVM] Fixed initialization procedure in InitNVMConfig() to validate start address and partition_size.

- [wireless_nbu] Fixed resource access issue by reverting TSTMR read restriction on NBU as underlying issue has been resolved.
- [wireless_mcu][wireless_nbu] Fixed timestamp initialization to ensure defined value when tstmrId is out of range.
- [SecLib_RNG] Corrected copyright header in seclib.c.
- [MISRA] Various MISRA and CERT-C compliance fixes in NVM module.

7.3.1 mcux SDK 26.06.00 pvw1

Major Changes

- [SecLib_RNG] Refactored SecLib mutex declaration and made Lock/Unlock functions public. Changed return type from osa_status_t to secResultType_t for SecLib mutex functions and moved mutex Lock/Unlock function declarations to SecLib.h.
- [SecLib_RNG][PSA] Activated PSA opaque execution with s200 and its secure key storage. Switched from PSA transparent mode to opaque mode for all functions except CMAC_LsbFirstInput() which is currently not supported in opaque version. Optimized SecLib_psa_config to fully accelerate all PSA_WANT_KEY_TYPE_ECC_KEY_PAIR functions.

Minor Changes

- [RW61X] Added new API PLATFORM_BlePriorityRemap() with HCI vendor command HCI_CMD_NXP_REMAP_BLE_PRIORITY 0x2A1 to configure BLE ADV and Connection Priority relative to Wi-Fi/OT.
- [DBG] Disabled DTEST signals and GPIO debug for debug target to prevent significant low power current consumption degradation.

Bug Fixes

- [OTA][Coverity] Sanitized pImageOffset parameter in OTA functions to avoid possible overflow.
- [SecLib] Fixed multiplication buffer pointer initialization for segmented ECDH operations. Fixed EC P256 multistep operations using SW legacy library. Fixed ECDH_P256_ComputeDhKeySeg() and ECDH_P256_GenerateKeysSeg() argument checking across SecLib variants. Fixed SecLib_AES_CMAC_PRF_128() behavior for SecLib sss variant that tolerated VK length to be 0. Removed unreachable code from SecLib_HMAC_SHA256_Finish().
- [Platform] Fixed TSTMR timestamp 64 bit read compilation failure when gPlatformTstmr32Bit_d is undefined.

7.2.3 mcux SDK 26.03.00 RFP

Major Changes

- [SecLib] Refactored SecLib functions with improved error handling and naming conventions. Added return status codes for better testing, added SecLib_ prefix for all functions with backward compatibility maintained via #define stubs. Added parameter checks on all functions and improved test coverage for all SecLib flavors.
- [SecLib] Updated CryptoLibSW APIs by removing unused pMultiplicationBuffer argument from Ecdh_ComputeDhKeyUltraFast(), ECP256_GeneratePublicKeyUltraFast(), and ECP256_GenerateKeyPairUltraFast(). Renamed ECP256_GeneratePublicKey() to ECP256_GeneratePublicKeySeg() in legacy implementation. Added new ECP256_GeneratePublicKey() API for SPAKE2+ ComputeL procedure.

Minor Changes

- [FunctionLib] Enhanced FLib_StrLen() to return error value when string size exceeds maximum limit (4096 bytes), adopting strnlen behavior.
- [Common] Cleaned deprecated mbedtls2x Kconfig configurations.
- [wireless_mcu][lcl] Updated FEM API to send configuration to NBU for proper XCVR timing adaptation during Channel Sounding activity. XCVR register backup and restore uses current mechanism with config sent through PLATFORM_NbuApiReq().
- [Kconfig] Fixed KCONFIG dependency loop related to MCUX_COMPONENT_component.wifi_bt_module.config by switching MCUX_COMPONENT_driver.conn_fwloader from select to depends on.
- [SecLib_RNG] Removed support for deprecated devices including FSL_FEATURE_SOC_SIM_COUNT RNG and QN908x platform.
- [FactoryDataProvider] Removed deprecated FactoryDataProvider service as it is no longer used following mbedtls2.x deprecation.

Bug Fixes

- [wireless_mcu] Fixed FRO6M calibration failure in OEM closed lifecycle by replacing inaccessible DWT cycle counter with SysTick timer. The implementation saves/restores SysTick state to maintain FreeRTOS compatibility.
- [wireless_mcu][ble] Removed redundant assert in PLATFORM_SendHciVendorEvent() as invalid parameters are already sanitized with error returned to caller.
- [SecLib] Fixed CMakeLists.txt lib_crypto variant dependency.
- [MISRA] Various MISRA compliance fixes in OTA, flash related files, FSCI, NVM, platform files, and ICS modules. Fixed potential flash blank check issue with unaligned pointers, split OTA_PostWriteToFlash() to match HIS_LEVEL constraint, prevented infinite loop in FLib_StrLen(), and ensured union has consistent non-zero size across compilers.

7.2.2 mcux SDK 26.03.00 pvw2

Major Changes

- [wireless_mcu][ble] Refactored BLE platform into separate core HCI and utilities modules for improved modularity and Zephyr compatibility. Core HCI transport functions remain in fwk_platform_ble.c while utility functions (BD address generation, security, TX power, timestamps) moved to new fwk_platform_ble_utils.c module. This enables minimal HCI-only builds without hardware parameter, RNG, or controller API dependencies.
- [wireless_mcu][ble] Aligned HCI platform APIs with Zephyr driver requirements. PLATFORM_SetHciRxCallback() now returns int instead of void, added new PLATFORM_StartHci() API, and enhanced PLATFORM_InitBle() with initialization guard to prevent multiple initialization attempts.
- [wireless_mcu][ble] Made optional initialization steps configurable in PLATFORM_InitBle() with new flags gPlatformSetBleMaxTxPowerAtInit_d, gPlatformSetSfcConfigAtInit_d, and gPlatformSetWakeUpDelayAtInit_d to enable cleaner integration with Zephyr and minimal configurations.
- [wireless_mcu][wireless_nbu] Added new APIs: PLATFORM_TSTMR_GetBase(), PLATFORM_TSTMR_Enable(), and modified PLATFORM_TSTMR_ReadTimeStamp() to use TSTMR instance ID rather than pointer. Removed dependencies on MCUX component tstmr.
- [SecLib_RNG] Removed legacy SecLib and RNG mbedtls framework implementations now replaced by PSA. Removed deprecated SecLib AES-MMO implementation.

- [RNG] Introduced gRngEnableAutoReseed_d feature flag to control automatic reseeding via WorkQ. Defaults to enabled for platforms with NBU, disabled otherwise. This allows single-core platforms to use RNG without WorkQ dependency when handling reseeding manually.

Minor Changes

- [wireless_mcu][ot] Conditionally exclude MCUXpresso-specific dependencies (board_platform.h, pin_mux.h, SecLib.h, RNG_Interface.h, HWParameter.h) when building for Zephyr, with stubbed IEEE 802.15.4 address generation functions.
- [wireless_mcu] Made TRDC driver dependency optional based on gPlatformNbuDebugGpioDAccessEnabled_d usage, changing from mandatory (select) to optional (imply) in Kconfig.
- [wireless_nbu] Added new NBU APIs PLATFORM_GetSharedMemConfig() and PLATFORM_GetDMemConfig() to retrieve size of SMU/DMEM.
- [NVM] Added Nv_GetPartitionAddressAndSize() API to retrieve NVM partition characteristics.
- [DBG] Added warning ID tracking support with enhanced NBUDBG_StateCheck() to monitor NBU warnings. Added PLATFORM_IsNbuWarningSet() API with callback support for proactive warning monitoring.
- [DBG] Added HCI vendor event transmission support with NBUDBG_ConfigureHciVendorEvent() API to enable/disable debug structure transmission over HCI.
- [DBG] Added coredump support on fault handler with gFaultHandlerCoredumpEnabled_d conditional compilation.
- [DBG] Initialized .debugbuf from flash into sqram_debug_region for GCC builds with INIT_BLE_DEBUG_DAT.
- [Sensors] Added initialization guard to prevent redundant sensor initialization calls with PLATFORM_InitSensors().
- [Platform] Added missing localization dependency to XCVR in Kconfig.
- [Platform] Fixed missing Kconfig dependencies for KW47 core1 variants (KW47B42ZB2, KW47B42ZB3, KW47B42ZB6, KW47B42Z96, KW47B42Z97).
- [MCXW23] Enabled gSecLibUseDspExtension_d to leverage CM33 DSP extensions for ultra-fast cryptographic library.
- [MCXW23] Changed temperature dummy value for sensors to support application enablement.
- [OTA] Improved OTA coverage by allowing static functions to be invoked from unit tests.
- [FSCI] Added UUID retrieval via PLATFORM_GetMCUUid() abstraction in FSCI_ReadNbuVer() API.
- [Common] Made services CMakeLists optional to allow integration of only required services into Zephyr's hal_nxp.
- [Platform] Made timer manager optional with configuration flag.
- [wireless_mcu][lcl] Corrected FEM & COEX API functions with proper NBU wake-up handling and RF_GPO pin conflict checks.
- [wireless_mcu] Consolidated KB() and MB() macro definitions by using fwk_hal_macros.h instead of platform-specific definitions to prevent conflicts and ensure Zephyr compatibility.
- [Common] Added Zephyr RTOS compatibility to fwk_hal_macros.h by including <zephyr/sys/util.h> when __ZEPHYR__ is defined and guarding _DO_CONCAT and CONTAINER_OF macros to prevent redefinition conflicts.

Bug Fixes

- [SecLib_RNG][PSA] Fixed RNG and PSA context release in RNG_Deinit() by invoking mbedtls_psa_crypto_free() and resetting rng_ctx.mRngInitialized to ensure proper reinitialization in RNG_ReInit().
- [NVM] Fixed GetFlashTableVersion() function to prevent recursion
- [NVM] Treated missing error case in NvCopyRecord() if failed to find record.
- [NVS] Fixed blank check procedure to return false (non-blank) when checking a 0 length area and corrected internal flash blank check of unaligned flash data.
- [SecLib] Initialized CMAC context before using it to prevent usage of uninitialized memory.
- [WorkQ] Increased workqueue stack size when coverage is enabled.
- [wireless_mcu] Fixed build issue when ICS WorkQ is disabled.
- [MISRA] Various MISRA and CERT-C compliance fixes in NVM, HWParameter, DBG (including platform dbg), LowPower, SecLib, Platform modules (platform_ics, platform_sensors), FSCI, FunctionLib, wireless_mcu, and Common modules.

7.2.1 mcux SDK 26.03.00 pvw1

Major Changes

- [wireless_mcu][ot] Removed gPlatformUseOuiFromIfr configuration flag. OUI will now be read from IFR by default on mcxw72 platform, with a fallback to the static OUI if no value is found in IFR.
- [wireless_mcu][ble] Enabled gPlatformUseUniqueDeviceIdForBdAddr_d = 2 on kw47/mcxw72 platforms to read the complete BD address from IFR. If no address is found in IFR, the system will fall back to generating one using the RNG method.
- [SecLib] Removed unused cryptographic implementations (SHA1, AES-EAX, AES-OFB) and obsolete FSL_FEATURE_SOC_AES_HW option to reduce code size and complexity.

Minor Changes

- [wireless_mcu][ble] Added callback registration for HCI log. Users can register a callback to log the HCI commands sent/received on the platform using new wrapper API.
- [wireless_nbu][CS][COEX] Added Channel Sounding (CS) coexistence enablement support.

Bug fixes

- [wireless_nbu][lowpower] Fixed NBU low-power timing issue by forcing LPO delay to 0 during active NBU window. The delay is restored to the default parameter right before re-entering low-power mode to guarantee accurate Link Layer timing calculations.
- [platform] Removed PLATFORM_GetClockFreq() API which contained MISRA violations, was unused, and duplicated PLATFORM_GetNbuFreq() functionality.
- [MISRA] Various MISRA compliance fixes in SFC, SecLib, Platform (including platform_ics and platform low power), FSCI, and PDUM modules.

7.1.3 mcux SDK 25.12.00 RFP

Major Changes

- [wireless_mcu][wireless_nbu] Replaced interrupt masking macros with static inline functions PLATFORM_SetInterruptMask() and PLATFORM_ClearInterruptMask() to ensure consistent BASEPRI value handling across all compilers. This addresses compiler-dependent behavior issues with the previous macro implementation.
- [wireless_mcu] Added BASEPRI-based interrupt masking in PLATFORM_RemoteActiveRel() to allow high-priority IRQs while ensuring only IMU0 or thread context can call this function.
- [wireless_mcu] Introduced gPlatformUseHwParameter_d compile flag to allow builds without HWParameter section. When undefined or set to 0, crystal trimming functions conditionally access HWParameters only when required.

Minor Changes

- [kw47_mcxw72] Introduced platform-specific library for KW47/MCXW72 platforms.
- [kw47_mcxw72] Support for additional KW47 phantoms including ZB2/ZB3/ZB6/ZB7 and Z83/Z96/Z97.
- [kw47_mcxw72] Removed SH_MEM_TOTAL_SIZE override as it is now automatically calculated to match rpmsg-lite configuration.
- [wireless_mcu] Set RL_BUFFER_PAYLOAD_SIZE to word-aligned value as expected by rpmsg-lite.
- [wireless_mcu] Added system-generated HCI vendor events capability for debug and diagnostic purposes.
- [DBG] Added debug structure transmission over HCI vendor events with NBUDBG_ConfigureHciVendorEvent() API to enable/disable the feature.
- [DBG] Added debug structure versioning and logging buffer address/size information to debug structure.
- [DBG] Removed 15.4 region from debug structure as not supported on KW47.
- [DBG] Added stack overflow detection for armv8_m_mainline architecture.
- [Platform] Simplified enablement of reset features via pin detection
  - Automatically selects gUseResetByLvdForce_c when gAppForceLvdResetOnResetPinDet_d is enabled.
  - Automatically select gUseResetByDeepPowerDown_c when gAppForceDeepPowerDownResetOnResetPinDet_d is enabled.
- [RNG] Replaced gRngHasSecLibDependency_d compilation switch with gRngUseSecLib_d.
- [mcxw23] Defined gRngIsrPrio_c on the preprocessor to make it global and avoid redefinition warnings.
- [mcxw23] Implemented PLATFORM_ResetCrypto() API called by RNG_reinit/SecLib_reinit.
- [mcxw23] Added support of Timer Manager timestamp with OSTIMER.

Bug fixes

- [wireless_mcu] Fixed race condition in PLATFORM_RemoteActiveRel() by adding verification loop to confirm NBU core execution before releasing power domain.
- [wireless_mcu] Added instruction synchronization barrier (__ISB()) after interrupt reenable in PLATFORM_RemoteActiveRel() to ensure pending interrupts execute between critical sections.
- [wireless_mcu] Fixed external IO voltage isolation issue during low-power initialization - isolation is now cleared at init to ensure proper behavior.

- [wireless_mcu] Replaced spin-wait loops with event-based synchronization in NBU communication APIs. Added mutex protection to PLATFORM_NbuApiReq() and PLATFORM_GetNbuInfo() to prevent race conditions and deadlocks when multiple tasks call these APIs concurrently.
- [wireless_mcu] Fixed OSA bare metal event race condition in ICS where auto-clear event feature could cause tasks to become permanently stuck. Disabled auto-clear feature in bare metal builds and manually clear event flags after OSA_EventWait() returns successfully.
- [NVM] Fixed NvIdle() to prevent looping for more operations than the queue size.
- [NVS] Fixed blank check procedure to return false (non-blank) when checking a 0 length area.
- [NVS] Made external and internal flash ports consistent.
- [DBG] Fixed debug structure size and callback access issues - corrected memory placement overlap between reg_info and assert_info.
- [MISRA] Various MISRA compliance fixes in NVM, HWParameter, LowPower, SecLib, Platform modules and IFR offset definitions.

7.1.2 mcux SDK 25.12.00 pvw2

Major Changes

- [wireless_mcu] Reduced RPMSG buffer payload size from 496 to 270 bytes on KW43/KW47 platforms, saving 226 bytes per buffer (1808 bytes total with 4 buffers on each core). This optimization is possible as rpmsg-lite no longer requires buffer sizes to be powers of two.
- [configs] Introduced RL_ALLOW_CUSTOM_SHMEM_CONFIG flag in rpmsg_config.h to enable connectivity applications to use platform_set_static_shmem_config() and platform_get_custom_shmem_config().

Minor Changes

- [wireless_mcu] Updated radio power management configuration with PLATFORM_InitRadio() API on kw47/mcxw72 platforms
- [DBG] Added NBU assert indication support to host with line/file info using debug structure.
- [DBG] Enhanced NBU debug framework with warning detection and notification capabilities. Extended NBUDBG_StateCheck() to monitor NBU warnings via PLATFORM_IsNbuWarningSet() with callback support for proactive warning monitoring.
- [Sensors] Added periodic temperature measurement support allowing app/host to request periodic temperature measurement.
- [Sensors] Added markdown documentation explaining periodic measurement functionality upon NBU requests.
- [SecLib_RNG] Added documentation for asynchronous seed handling using RNG_NotifyReseedNeeded() and SecLib implementation flavors (Software, EdgeLock, PSA Crypto, MbedTLS).
- [PSA] Simplified PSA configuration files and reduced imports/definitions for wireless MCU platforms.
- [mcxw23] Changed temperature dummy value for sensors to progress on application enablement.
- [NVS] Enhanced debug capabilities by adding CONFIG_NVS_LOG_LEVEL and improved LOG macros to adapt to PRINTF limitations.

Bug fixes

- [wireless_mcu] Fixed FRO32K as 32 kHz clock source with deferred OSC32K switching to improve initialization performance after warm reset.
- [wireless_mcu] Added wait loop for NBU power domain readiness in PLATFORM_InitNbu() to prevent race conditions when accessing NBU power domain in applications without NBU images.
- [wireless_mcu] Fixed external flash blank check procedure for LSPI external NOR Flash by correcting PLATFORM_ExternalFlashAreaIsBlank() to read from RAM buffer and perform erase pattern comparison in RAM with optimized 4-byte step loops.
- [NVS] Removed mflash dependency from NVS external flash port and fixed internal flash blank check of unaligned flash data.
- [mcxw23] Ensured TX power does not exceed 6dBm maximum limit.

7.1.1 mcux SDK 25.12.00 pvw1

Minor Changes

- [wireless_mcu][wireless_nbu] Migrated TSTMR implementation to use SDK fsl_tstmr driver for better maintainability and consistency. This migration replaces custom TSTMR register definitions with official SDK driver APIs while maintaining existing PLATFORM_* API compatibility.

Bug fixes

- [SecLib_RNG][mbedtls] Enhanced ECDH context preservation across low-power transitions on KW45_MCXW71 and KW47_MCXW72 platforms using export/import APIs to ensure cryptographic context is retained when hardware accelerator loses internal memory during power-down mode.
- [wireless_nbu] Fixed incorrect FRODIV values that were causing reduced peripheral clocks by updating PLATFORM_FroDiv[] mapping array to prevent over-division of flash APB and RF_CMC clocks.
- [rw61x/rt1060/rt1170] Added missing common files for external and OTA support on rw61x/rt1060/rt1170 platforms.

7.0.3 RFP mcux SDK 25.09.00

Major Changes

- [wireless_mcu] Replaced ICS RX linked list with message queue to eliminate memory allocation in ISR context and enable user callbacks to run in thread context where memory allocation is permitted.
- [wireless_mcu] Added HCI RX workqueue processing support to reduce ISR execution time and system impact. Feature controlled by gPlatformHciUseWorkqueueRxProcessing_d configuration option (enabled by default on kw45_k32w1_mcxw71 and kw47_mcxw72 platforms in freertos applications). When enabled, HCI transport processes received data in system workqueue thread, allowing user callbacks to run in thread context.
- [wireless_nbu] Introduced PLATFORM_ConfigureSmuDmemMapping() API to configure SMU and DMEM sharing on NBU for kw47_mcxw72 platform, using linker file symbols for correct configuration.
- [mcxw23] Implemented HCI interface using PLATFORM API as preliminary requirement for Zephyr enablement, introducing PLATFORM_SendHciMessageAlt() alternative API.
- [wireless_mcu][wireless_nbu] Added NBU2Host event manager for status indications to host (Information, Warning, Error) sent over RPMSG.

- [wireless_mcu] Added a call to PLATFORM_IcsRxWorkHandler() within PLATFORM_NbuApiReq() for baremetal applications to prevent potential deadlocks.

Minor Changes

- [wireless_mcu] Fixed variable underflow issue in PLATFORM_RemoteActiveRel().
- [SecLib_RNG] Fixed escaping local HashKeyBuffer address issue and added missing cast in RNG_GetTrueRandomNumber() function.
- [Common] Fixed heap memory manager return values and added missing include to fwk_freertos_utils.h.
- [rw61x] Prevented array out of bounds in PLATFORM_RegisterRtcHandle().
- [FSCI] Fixed memory leak in FSCI module.
- [NVM] Enhanced debug facilitation by restricting variable scope, assigning return statuses to variables, and fixing display format in NV_ShowFlashTable().
- [wireless_mcu] Added new chip revision A2.1 support in PLATFORM_SendChipRevision() API.
- [kw47_mcxw72] Implemented BLE BD address retrieval from IFR memory with fallback to OUI + RNG.
- [DBG] Added ThreadX support to fault handlers and reworked fault handler structure with dedicated RTOS files.
- [DBG][Common] Added NBU debug support on host side to detect faults and system errors, with debug info extraction capability (limited to MCXW72/KW47).
- [Common] Platform CMake rework and Kconfig renaming, removing unneeded checks and renaming PRJSEG platform Kconfigs to COMPONENT.
- [mcxw23] Added experimental SecLib PSA support with additional configuration for MBEDTLS_ECP_C and MBEDTLS_BIGNUM_C.
- [wireless_mcu] Cleaned CMakeLists.txt to avoid wrong inclusions of files and folders from incorrect platforms.
- [wireless_mcu][wireless_nbu] Added NBU2Host warning when 32MHz crystal is unready on low power exit.
- [wireless_mcu][ot] Introduced gPlatformUseOuiFromIfr to use OUI from IFR for the extended address (disabled by default). When enabled and IFR is not blank, copies first three bytes to OUI field of extended address, otherwise uses static OUI as fallback.
- [General] Removed useless warning about TSTMR_CLOCK_FREQUENCY_MHZ definition.
- [General] Updated framework license and SBOM for 25.09 RFP release.
- [wireless_mcu] Fixed unused variable warning when gPlatformIcsUseWorkqueueRxProcessing_d and gPlatformHciUseWorkqueueRxProcessing_dare disable

7.0.3 revB mcux SDK 25.09.00

Major Changes

- [wireless_mcu] Adjusted default value of BOARD_RADIO_DOMAIN_WAKE_UP_DELAY from 0x16 to 0x10 to address stability issues observed with the previous setting. This change enhances system reliability but will reduce low-power performance.

Minor Changes (bug fixes)

- [Common] Added MDK compatibility for the errno framework header.

- [mcxw23] Implemented missing PLATFORM_OtaClearBootInterface() API.
- [mcxw23] Refactored fwk_platform.c to separate BLE-specific logic into fwk_platform_ble.c.
- [OTA] Corrected definition of gEepromParams_WriteAlignment_c flag for mcxw23
- [OTA] Enabled calling OTA_GetImgState() prior to OTA_Initialize().
- [wireless_mcu] Fixed PLATFORM_IsExternalFlashSectorBlank() to check the entire sector instead of just one page.
- [mcxw23] Added support for OTA using external flash.
- [mcxw23] Introduced PLATFORM_GetRadioIdleDuration32K() to estimate time until next radio event.
- [OTA] Removed gUseInternalStorageLink_d linker flag definition when external OTA storage is used.
- [mcxw23] Extended CopyAndReboot() to support external flash OTA.
- [wireless_mcu] Resolved counter wrap issue in PLATFORM_GetDeltaTimeStamp().
- [kw43_mcxw70] Defined LPTMR frequency constants in fwk_platform_definitions.h.
- [kw47_mcxw72] Updated shared memory allocation for RPMsg adapter.
- [mcxw23] Implement PLATFORM_IsExternalFlashBusy() API.
- [kw45_mcxw71][kw47_mcxw72] Moved RAM bank definitions from the connectivity framework to device-specific definitions.

7.0.3 revA mcux SDK 25.09.00

Major Changes

- [wireless_nbu] Enhanced XTAL32M trimming handling: updates are applied when requested by the application core and the NBU enters low-power mode, ensuring no interference from ongoing radio activity. Introduced new APIs to lock (PLATFORM_LockXtal32MTrim()) and unlock XTAL32M (PLATFORM_UnlockXtal32MTrim()) trimming updates using a counter-based mechanism. Also added a reset API (PLATFORM_ResetContext()) for platform-specific variables (currently limited to the trimming lock).
- [wireless_mcu] Introduced a new API, PLATFORM_SetLdoCoreNormalDriveVoltage(), to enable support for NBU clock frequency at 64 MHz, as required by BLE channel sounding applications.
- [wireless_mcu][wireless_nbu] Increased delayLpoCycle default from 2 to 3 to address link layer instabilities in low-power NBU use cases. Adjusted BOARD_RADIO_DOMAIN_WAKE_UP_DELAY from 0x10 to 0x16 to balance power consumption and stability. NBU may malfunction if delayLpoCycle (or BOARD_LL_32MHz_WAKEUP_ADVANCE_HSLOT) is set to 2 while BOARD_RADIO_DOMAIN_WAKE_UP_DELAY is 0x16.

Minor Changes (bug fixes)

- [WorkQ] Increased stack size when RNG use mbedtls port and coverage is enabled.
- [FSCI] Resolved an issue where messages remained unprocessed in the queue by ensuring OSA_EventSet() is triggered when pending messages are detected.
- [OTA] Fixed a bug in in OTA_PullImageChunk() that prevented retrieval of data previously received via OTA_PushImageChunk() when still buffered in RAM during posted operations.
- [OTA] Various MISRA and coverity fixes.

- [mcxw23] Fixed an unused variable warning in PLATFORM_RegisterNbuTemperatureRequestEventCb() API.
- [SFC] Remove obsolete flag gNbuJtagCapability.
- [wireless_mcu] Introduced new API PLATFORM_GetRadioIdleDuration32K(). Deprecated PLATFORM_CheckNextBleConnectivityActivity() API.
- [mcxw23] Aligned platform-specific implementations with the corresponding prototypes defined in wireless_mcu.
- [DBG] Cleaned up fwk_fault_handler.c.

7.0.2 RFP mcux SDK 25.06.00

Major Changes

- [wireless_mcu][wireless_nbu] Introduced PLATFORM_Get32KTimeStamp() API, available on platforms that support it.
- [RNG] Switched to using a workqueue for scheduling seed generation tasks.
- [Sensors] Integrated workqueue to trigger temperature readings on periodic timer expirations.
- [wireless_nbu] Removed outdated configuration files from wireless_nbu/configs.
- [SecLib_RNG][PSA] Added a PSA-compliant implementation for SecLib_RNG. This is an experimental feature and should be used with caution.
- [wireless_mcu][wireless_nbu] Implemented PLATFORM_SendNBUXtal32MTrim() API to transmit XTAL32M trimming values to the NBU.

Minor Changes (bug fixes)

- [MWS] Migrated the Mobile Wireless Standard (MWS) service to the public repository. This service manages coexistence between connectivity protocols such as BLE, 802.15.4, and GenFSK.
- [HWParameter][NVM][SecLib_RNG][Sensors] Addressed various MISRA compliance issues across multiple modules.
- [Sensors] Applied a filtering mechanism to temperature data measured by the application core before forwarding it to the NBU, improving data reliability.
- [Common] Relocated the GetPowerOfTwoShift() function to a shared module for broader accessibility across components.
- [RNG] Resolved inconsistencies in RNG behavior when using the fsl_adapter_rng HAL by aligning it with other API implementations.
- [SecLib] Updated the AES CMAC block counter in AES_128_CMAC() and AES_128_CMAC_LsbFirstInput() to support data segments larger than 4KB.
- [SecLib] Utilized sss_sscp_key_object_free() with kSSS_keyObjFree_KeysStoreDefragment to avoid key allocation failures.
- [MCXW23] Removed redundant NVIC_SetPriority() call for the ctimer IRQ in the platform file, as it's already handled by the driver.
- [WorkQ] Increased workqueue stack size to accommodate RNG usage with mbedtls.
- [wireless_mcu][ot] Suppressed chip revision transmission when operating with nbu_15_4.
- [platform][mflash] Ensured proper address alignment for external flash reads in PLATFORM_ReadExternalFlash() when required by platform constraints.

- [RNG] Corrected reseed flag behavior in RNG_GetPseudoRandomData() after reaching gRngMaxRequests_d threshold.
- [platform][mflash] Fixed uninitialized variable issue in PLATFORM_ReadExternalFlash().
- [platform][wireless_nbu] Fixed an issue on KW47 where PLATFORM_InitFro192M incorrectly reads IFR1 from a hardcoded flash address (0x48000), leading to unstable FRO192M trimming. The function is now conditionally compiled for KW45 only.

7.0.2 revB mcux SDK 25.06.00

Major Changes

- [RNG][wireless_mcu][wireless_nbu] Rework RNG seeding on NBU request
- [wireless_mcu] [LowPower] Add gPlatformEnableFro6MCalLowpower_d macro to enable FRO6M frequency verification on exit of Low Power
  - add PLATFORM_StartFro6MCalibration() and PLATFORM_EndFro6MCalibration() new function for FRO6M calibration (6MHz or 2Mhz) on wake-up from low power mode.
  - Enabled by default in fwk_config.h
- [wireless_nbu][LowPower] Clear pending interrupt status of the systick before going in low-power - Reduce NBU active time
- [wireless_nbu] Fix impossibility to go to WFI in combo mode (15.4/BLE)
- [wireless_mcu] Implement XTAL32M temperature compensation mechanism. 2 new APIs:
  - PLATFORM_RegisterXtal32MTempCompLut(): register the temperature compensation table for XTAL32M.
  - PLATFORM_CalibrateXtal32M(): apply XTAL32M temperature compensation depending on current temperature.
- [Sensors][wireless_mcu] Add support for periodic temperature measurement. new API:
  - SENSORS_TriggerTemperatureMeasurementUnsafe(): to be called from Interrupt masked critical section, from ISR or when scheduler is stopped
- [SFC] Change default maximal ppm target of the SFC algorithm from 200 to 360ppm. Impact the SFC algorith of kw45 and mcxw71 platforms, 360ppm was already the default setting for kw47 and mcxw72 platforms

Minor Changes (bug fixes)

- [DBG] Fix FWK_DBG_PERF_DWT_CYCLE_CNT_STOP macro
- [wireless_nbu] Add gPlatformIsNbu_d compile Macro set to 1
- [wireless_nbu][ics] gFwkSrvHostChipRevision_c can be processed in the system workqueue
- [kw45_mcxw71][kw47_mcxw72]
  - Remove LTC dependency from platform in kconfig
  - gPlatformShutdownEccRamInLowPower moved from fwk_platform_definition.h to fwk_confg.h as this is a configuration flag.
- [wireless_mcu][sensors] Rework and remove unnecessary ADC APIs
- [wireless_nbu] Add PLATFORM_GetMCUUid() function from Chip UID
- [SecLib] Change AES_MMO_BlockUpdate() function from private to public for zigbee.

7.0.2 revA mcux SDK 25.06.00

Supported platforms:

- Same as 25.03.00 release

Major Changes

- [KW45/MCXW71] HW parameters placement now located in IFR section. Flash storage is not longer used:
  - Compilation: Macro gHwParamsProdDataPlacement_c changed from gHwParamsProdDataMainFlash2IfrMode_c to gHwParamsProdDataIfrMode_c
- [KW47] NBU: Add new fwk_platform_dcdc.[ch] files to allow DCDC stepping by using SPC high power mode. This requires new API in board_dcdc.c files. Please refer to new compilation MACROs gBoardDcdcRampTrim_c and gBoardDcdcEnableHighPowerModeOnNbu_d in board_platform.h files located in kw47evk, kw47loc, frdmmcxw72 board folders.
- [KW45/MCXW71/KW47/MCXW72] Trigger an interrupt each time App core calls PLATFORM_RemoteActiveReq() to access NBU power domain in order to restart NBU core for domain low power process

Minor Changes (bug fixes)

Services

- [SecLib_RNG]
  - Rename mSecLibMutexId mutex to mSecLibSssMutexId in SecLib_sss.c
  - Remove MEM_TRACKING flag from RNG.c
  - Implement port to fsl_adapter_rng.h API using gRngUseRngAdapter_c compil Macro from RNG.c
  - Add support for BLE debug Keys in SecLi and SecLin_sss.c with gSecLibUseBleDebugKeys_d - for Debug only
- [FSCI] Add queue mechanism to prevent corruption of FSCI global variableAllow the application to override the trig sample number parameter when gFsciOverRpmsg_c is set to 1
- [DBG][btsnoop] Add a mechanism to dump raw HCI data via UART using SBTSNOOP_MODE_RAW
- [OTA]
  - OtaInternalFlash.c: Take into account chunks smaller than a flash phrase worth
  - fwk_platform_ot.c: dependencies and include files to gpio, port, pin_mux removed

Platform specific

- [kw45_mcxw71][kw47_mcxw72]
  - fwk_platform_reset.h : add compil Macro gUseResetByLvdForce_c and gUseResetByDeepPowerDown_c to avoid compile the code if not supported on some platforms
  - New compile Flag gPlatformHasNbu_d
  - Rework FRO32K notification service for MISRA fix

7.0.1 RFP mcux SDK 25.03.00

Supported platforms:

- KW45x, KW47x, MCXW71, MCXW72, K32W1x
- RW61x

- RT595, RT1060, RT1170
- MCXW23

Minor Changes (bug fixes)

- [General] Various MISRA/Coverity fixes in framework: NVM, RNG, LowPower, SecLib and platform files

Services

- [SecLib_RNG] fix return status from RNG_GetTrueRandomNumber() function: return correctly gRngSuccess_d when RNG_entropy_func() function is successful
- [SFC] Allow the application to override the trig sample number parameter
- [Settings] Re-define the framework settings API name to avoid double definition when gSettingsRedefineApiName_c flag is defined

Platform specific

- [wireless_mcu] fwk_platform_sensors update :
  - Enable temperature measurement over ADC ISR
  - Enable temperature handling requested by NBU
- [wireless_mcu] fwk_platform_lcl coex config update for KW45
- [kw47_mcxw72] Change the default ppm_target of SFC algorithm from 200 to 360ppm

7.0.1 revB mcux SDK 25.03.00

Supported platforms:

- KW45x, KW47x, MCXW71, MCXW72, K32W1x
- RW61x
- RT595, RT1060, RT1170
- MCXW23

Minor Changes (bug fixes)

General

- [General] Various MISRA/Coverity fixes in framework: NVM, RNG, LowPower, FunctionLib and platform files

Services

- [SecLib_RNG] AES-CBC evolution:
  - added AES_CBC_Decrypt() API for sw, SSS and mbedtls variants.
  - Made AES-CBC SW implementation reentrant avoiding use of static storage of AES block.
  - fixed SSS version to update Initialization Vector within SecLib, simplifying caller's implementation.
  - modified AES_128_CBC_Encrypt_And_Pad() so as to avoid the constraint mandating that 16 byte headroom be available at end of input buffer.
- [SecLib_RNG] RNG modifications:

  - RNG_GetPseudoRandomData() could return 0 in some error cases where caller expected a negative status.
    * Explicited RNG error codes
    * Added argument checks for all APIs and return gRngBadArguments_d (-2) when wrong
    * added checks of RNG initalization and return gRngNotInitialized_d (-3) when not done
    * fixed correcteness of RNG_GetPrngFunc() and RNG_GetPrngContext() relative to API description.
    * Added RNG_DeInit() function mostly for test and coverage purposes.
    * Improved RNG description in README.md
    * Unified the APIs behaviour between mbedtls and non mbedtls variants.
  - RNG/mbedtls : Prevent RNG_Init() from corrupting RNG entropy context if called more than once.
  - RNG/mbedtls: fixed RNG_GetTrueRandomNumber() to return a proper mbedtls_entropy_func() result.
  - Use defragmetation option when freeing key object in SecLib_sss to avoid leak in S200 memory
  - Add new API ECP256_IsKeyValid() to check whether a public key is valid
- [OtaSupport] Update return status to OTA_Flash_Success when success at the end of InternalFlash_WriteData() and InternalFlash_FlushWriteBuffer() APIs
- [WorQ] Implementing a simple workqueue service to the framework
- [SFC] Keep using immediate measurement for some measurement before switching to configuration trig to confirm the calibration made
- [DBG] Adding modules to framework DBG :
  - sbtsnoop
  - SWO
- [Common] Fix HAL_CTZ and HAL_RBIT IAR versions
- [LowPower] Fix wrong tick error calculation in case of infinite timeout
- [Settings] Add new macro gSettingsRedefineApiName_c to avoid multiple definition of settings API when using connectivity framework repo

Platform specific

- [KW47/MCXW72] Change xtal cload default value from 4 to 8 in order to increase the precision of the link layer timebase in NBU
- [wireless_mcu] [wireless_nbu] Use new WorkQ service to process framework intercore messages
- [rw61x] Fix HCI message sending failure in some corner case by releasing controller wakes up after that the host has send its HCI message
- [MCXW23] Adding the initial support of MCXW23 into the framework

7.0.0 mcux SDK 24.12.00

Supported platforms:

- KW45x, KW47x, MCXW71, MCXW72, K32W1x

- RW61x
- RT595, RT1060, RT1170

Minor Changes (bug fixes)

Platform specific

- [RW61X]
  - Add MCUX_COMPONENT_middleware.wireless.framework.platform.rng to the platform to fix a warning at generation
  - Retrieve IEEE 64 bits address from OTP memory
- [KW45x, MCXW71x, KW47x, MCXW72x]
  - Ignore the secure bit from RAM addresses when comparing used ram bank in bank retention mechanism
  - Add gPlatformNbuDebugGpioDAccessEnabled_d Compile Macro (enabled by default). Can be used to disable the NBU debug capability using IOs in case Trustzone is enabled ("PLATFORM_InitNbu()' code executed from unsecure world).
  - Fix in NBU firmware when sending ICS messages gFwkSrvNbuApiRequest_c (from controller_api.h API functions)

Services

- [OTA]
  - Add choice name to OtaSupport flash selection in Kconfig
- [NVM]
  - Add gNvmErasePartitionWhenFlashing_c feature support to gcc toolchain
- [SecLib_RNG]
  - Misra fixes

7.0.0 revB mcux SDK 24.12.00

Supported platforms: KW45x, KW47x, MCXW71, MCXW72, K32W1x, RW61x, RT595, RT1060, RT1170

Major Changes (User Applications may be impacted)

- mcux github support with cmake/Kconfig from sdk3 user shall now use CmakeLists.txt and Kconfig files from root folder. Compilation should be done using west build command. In order to see the Framework Kconfig, use command >west build -t guiconfig
- Board files and linker scripts moved to examples repository

Bugfixes

- [platform lowpower]
  - Entering Deep down power mode will no longer call PLATFORM_EnterPowerDown(). This API is now called only when going to Power down mode

Platform specific

- [KW47/MCXW72]: Early access release only

  - Deep sleep power mode not fully tested. User can experiment deep sleep and deep down modes using low power reference design applications
  - XTAL32K-less support using FRO32K not tested
- [KW45/MCXW71/K32W148]
  - Deep sleep mode is supported. Power down mode is supported in low power reference design applications as experimental only
  - XTAL32K-less support using FRO32K is experimental - FRO32K notifications callback is debug only and should not be used for mass production firmware builds

Minor Changes (no impact on application)

- Overall folder restructuring for SDK3
  - [Platform]:
    * Rename platform_family from connected_mcu/nbu to wireless_mcu/nbu
    * platform family have now a dedicated fwk_config.h, rpmsg_config.h and SecLib_mbedtls_config.h
  - [Services]
    * Move all framework services in a common directory “services/”

7.0.0 revA: KW45/KW47/MCX W71/MCX W72/K32W148

Experimental Features only

- Power down on application power domain: Some tests have shown some failure. Power consumption higher than Deep Sleep. => This feature is not fully supported in this release
- XTAL32K less board with FRO32K support: Some additional stress tests are under progress.
- FRO32K notifications callback is for debug only and shall not be used for production. User shall not execute long processing (such as PRINTF) as it is executed in ISR context.

Main Changes

- Cmake/Kconfig support for SDK3.0
- [Sensors] API renaming:
  - $\mathrm{SENSORS\_InitAdc()}$ renamed to $\mathrm{SENSORS\_Init()}$
  - $\mathrm{SENSORS\_DeinitAdc()}$ remamed to $\mathrm{SENSORS\_Deinit()}$
- [HWparams]
  - Repair PROD_DATA sector in case of ECC error (implies loss of previous contents of sector)
- [NVM] Linker script modification for armgcc whenever gNvTableKeptInRam_d option is used:
  - placement of NVM_TABLE_RW in data initialized section, providing start and end address symbols. For details see NVM_Interface.h comments.
- [OtaSupport]
  - $\mathrm{OTA\_Initialize()}$: now transitions the image state from RunCandidate to Permanent if not done by the application. OTA module shall always be initialized on a Permanent image, this change ensures it is the case.
  - $\mathrm{OTA\_MakeHeadRoomForNextBlock()}$: now erases the OTA partition up to the image total size (rounded to the sector) if known.

Minor changes

- [Platform]
  - Updated macro values: -kw47: BOARD_32MHZ_XTAL_CDAC_VALUE from 12U to 16U, BOARD_32MHZ_XTAL_ISEL_VALUE from 7U to 11U, BOARD_32KHZ_XTAL_CLOAD_DEFAULT from 8U to 4U, BOARD_32KHZ_XTAL_COARSE_ADJ_DEFAULT from 1U to 3U
    * MCX W72 (low-power reference design applications only): BOARD_32MHZ_XTAL_CDAC_VALUE from 12U to 10U, BOARD_32MHZ_XTAL_ISEL_VALUE from 7U to 11U, BOARD_32KHZ_XTAL_CLOAD_DEFAULT from 8U to 4U, BOARD_32KHZ_XTAL_COARSE_ADJ_DEFAULT from 1U to 3U
  - New PLATFORM_RegisterNbuTemperatureRequestEventCb() API: register a function callback when NBU request new temperature measurement. API provides the interval request for the temperature measurement
  - Update PLATFORM_IsNbuStarted() API to return true only if the NBU firmware has been started.
- [platform lowpower]
  - Move RAM layout values in fwk_platform_definition.h and update RAM retention API for KW47/MCXW72

Bugfixes

- [OtaSupport]
  - OTA_MakeHeadRoomForNextBlock(): fixed a case where the function could try to erase outside the OTA partition range.

6.2.4: KW45/K32W1x/MCXW71/RX61x SDK 2.16.100

This release does not contain the changes from 6.2.3 release.

This release contains changes from 6.2.2 release.

Main Change

- armgcc support for Cmake sdk2 support and VS code integration

Minor changes

- [NBU]
  - Optimize some critical sections on nbu firmware
- [Platform]
  - Optimize PLATFORM_RemoteActiveReq() execution time.

6.2.3: KW47 EAR1.0

Initial Connectivity Framework enablement for KW47 EAR1.0 support.

New features

- OpenNBU feature : nbu_ble project is available for modification and building

Supported features

- Deep sleep mode

Unsuported features

- Power down mode
- FRO32K support (XTAL32K less boards)

Main changes

- [NBU]
  - LPTMR2 available and TimerManager initialization with Compile Macro: gPlatformUseLptmr_d
  - NBU can now have access to GPIOD
  - SW RNG and SW SecLib ported to NBU (Software implementation only)
- [RNG]
  - Obsoleted API removed : FWK_RNG_DEPRECATED_API
  - RNG can be built without SecLib for NBU, using gRngUseSecLib_d in fwk_config.h
  - Some API updates:
    * RNG_IsReseedneeded() renamed to RNG_IsReseedNeeded,
    * RNG_TriggerReseed() renamed to RNG_NotifyReseedNeeded(),
    * RNG_SetSeed() and RNG_SetExternalSeed() return status code.
  - Optimized Linear Congruential modulus computation to reduce cycle count.

Minor changes

- [NVM]
  - Optimize NvIsRecordErased() procedure for faster garbage collection
  - MISRA fix : Remove externs and weaks from NVM module - Make RNG and timer manager dependencies conditional
- [Platform]
  - Allow the debugger to wakeup the KW47/MCXW72 target

6.2.2: KW45/K32W1 MR6 SDK 2.16.000

Experimental Features only:

- Power down on application power domain : Some tests have shown some failure. Power consumption higher than Deep Sleep. => This feature is not fully supported in this release
- XTAL32K less board with FRO32K support : Some additional stress tests are under progress.
- FRO32K notifications callback is for debug only and shall not be used for production. User shall not execute long processing (such as PRINTF) as it is executed in ISR context.

Changes

- [Board] Support for freedom board FRDM-MCX W7X
- [HWparams]
  - Support for location of HWParameters and Application Factory Data IFR in IFR1
  - Default is still to use HWparams in Flash to keep backward compatibility
- [RNG]: API updates:

  - New APIS RNG_IsReseedneeded(), RNG_SetSeed() to provide See to PRNG on NBU/App core - See BluetoothLEHost_ProcessIdleTask() in app_conn.c
  - New APIs RNG_SetExternalSeed() : User can provide external seed. Typically used on NBU firmrware for App core to set a seed to RNG. RNG_TriggerReseed() : Not required on App core. Used on NBU only.
- [NVS] Wear statistics counters added - Fix nvs_file_stat() function
- [NVM] fix Nv_Shutdown() API
- [SecLib] New feature AES MMO supported for Zigbee

6.2.2: RW61x RFP4 SDK 2.16.000

- [Platform] Support Zigbee stack
- [OTA] Add support for RW61x OTA with remap feature.
  - Required modifications to prevent direct access to flash logical addresses when remap is active.
  - Image trailers expected at different offset with remap enabled (see gPlatformMcuBootUseRemap_d in fwk_config.h)
  - fixed image state assessment procedure when in RunCandidate.
- [NVS] Wear statistics counters added
- [SecLib] New feature AES MMO supported for Zigbee
- [Misra] various fixes

6.2.1: KW45/K32W1 MR5 SDK 2.15.000

Experimental Features only:

- Power down on application power domain : Some tests have shown some failure. This feature is not fully supported in this release
- XTAL32K less board with FRO32K support : Some additional stress tests are under progress. Timing variation of the timebase are being analyzed

Major changes

- [RNG]: API updates
  - New compile flag to keep deprecated API: FWK_RNG_DEPRECATED_API
  - change return error code to int type for RNG_Init(), RNG_ReInit()
  - New APIs RNG_GetTrueRandomNumber(), RNG_GetPseudoRandomData()
- [Platform]
  - fwk_platform_sensors
    - Change default temperature value from -1 to 999999 when unknown
  - fwk_platform_genfsk
    - rename from platform_genfsk.c/h to fwk_platform_genfsk.c/h
  - platform family
    - Rename the framework platform folder from kw45_k32w1 to connected_mcu to support other platform from the same family
  - fwk_platform_intflash

        * Moved from fwk_platform files to the new fwk_platform_intflash files the internal flash dependant API

- [NBU]
  - BOARD_LL_32MHz_WAKEUP_ADVANCE_HSLOT changed from 2 to 3 by default
  - BOARD_RADIO_DOMAIN_WAKE_UP_DELAY changed from 0x10 to 0x0F
- [gcc linker]
  - Exclude k32w1_nbu_ble_15_4_dyn.bin from .data section

Minor Changes

- [Platform]
  - PLATFORM_GetTimeStamp(0 has an important fix for reading the Timestamp in TSTMR0
  - New API PLATFORM_TerminateCrypto(), PLATFORM_ResetCrypto() called from SecLib for lowpower exit
  - Fix when enable fro debug callback on nbu
- [DBG]
  - SWO
    * Add new files fwk_debug_swo.c/h to use SWO for debug purpose
    * Two new flags has been added:
      · BOARD_DBG_SWO_CORE_FUNNEL to chose on which core you want to use SWO
      · BOARD_DBG_SWO_PIN_ENABLE to enable SWO on a pin
- [NVS]
  - Add support of NVS and Settings in framework
- [NBU]
  - Fix power down issues and reduce critical section on NBU side:
    * new API PLATFORM_RemoteActiveReqWithoutDelay() called from NBU functions where waiting delay is not required
    * Increase delay needed in power down for OEM part to request the SOC to be active
    * Remove unnecessary code to PLATFORM_RemoteActiveReqWithoutDelay() from PLATFORM_HciRpmsgRxCallback()
    * Improve nbu memory allocation failure debug messages
- [SDK]
  - Multicore: remove critical section in HAL_RpmsgSendTimeout() (only required in FPGA HDI mode)
  - Flash drivers: update for ECC detection
- [Platform]
  - fwk_platform_sensors
    * Fix temperature reporting to NBU
  - fwk_platform_extflash
    * Align .c and .h prototype of PLATFORM_ExternalFlashAreaIsBlank() function
- [NVM]

  - Keep Mutex in NvModuleDeInit(). In Bare metal OS, Mutex can not be destroyed
  - New API NvRegisterEccFaultNotificationCb() to register Notification callback when Ecc error happens in FileSystem
- [MISRA] fixes
  - SecLib_sss.c: ECDH_P256_ComputeDhKey()
  - fwk_platform_extflash.c: PLATFORM_IsExternalFlashPageBlank()
  - fwk_fs_abstraction.c: Various fixes
- [HWparams]
  - Fix on if condition when gHwParamsProdDataPlacementLegacy2IfrMode_c mode is selected
- [OTA]
  - Enable gOtaCheckEccFaults_d by default to avoid bus in case of ECC error during OTA
  - Fix OTA partition overflow during OTA stop and resume transfer
- [BOARD]
  - Place code button or led specific under correct defines in board_comp.c/h
  - Bring back MACROs BOARD_INITRFSWITCHCONTROLPINS in pin_mux header file of the loc board
- [SecLib]
  - Add some undefinition in SecLib_mbedtls_config as new dependency has been added in mbedtls repo:
    * MBEDTLS_SSL_CBC_RECORD_SPLITTING, MBEDTLS_SSL_PROTO_TLS1, MBEDTLS_SSL_PROTO_TLS1_1
- [FRO32K]
  - FRO32K notification callback PLATFORM_FroDebugCallback_t() has new parameter to report he fro_trim value
  - maxCalibrationIntervalMs value can be provided to NBU using PLATFORM_FwkSrvSetRfSfcConfig()
- [Sensors]
  - fix: PLATFORM_GetTemperatureValue() shall have NBU started to send temperature to NBU

6.2.1: RW61x RFP3

- [NVS]
  - Add support of NVS and Settings in framework
- [MISRA] fixes
  - board_lp.c BOARD_UninitDebugConsole() and BOARD_ReinitDebugConsole()
  - fwk_platform_ble.c: Various fixes
- [OTA]
  - Fix OTA partition overflow during OTA stop and resume transfer

6.2.0: RT1060/RT1170 SDK2.15 Major

6.1.8: KW45/K32W1 MR4

- [BOARD PLATFORM]
  - Move gBoardUseFro32k_d to board_platform.h file
  - Offer the possibility to change the source clock accuracy to gain in power consumption
- [BOARD LP]
  - Move PLATFORM_SetRamBanksRetained() at end of BOARD_EnterLowPowerCb() in case a memory allocation is done previously in this function
  - fix low power, increase BOARD_RADIO_DOMAIN_WAKE_UP_DELAY from 0 to 0x10 - Skip this delay when App requesting NBU wakeup
- [PLATFORM]
  - fwk_platform_ble.c/h: New timestamp API that returns the difference between the current value of the LL clock and the argument of the function
  - fwk_platform.c/h:
    * New PLATFORM_EnableEccFaultsAPI_d compile flag: Enable APIs for interception of ECC Fault in bus fault handler
    * New gInterceptEccBusFaults_d compile flag: Provide FaultRecovery() demo code for bus fault handler to Intercept bus fault from Flash Ecc error
- [LOC]
  - Incorrect behavior for set_dtest_page (DqTEST11 overridden)
  - Fix SW1 button wake able on Localization board
  - Fix yellow led not properly initialized
  - Format localization pin_mux.c/h files
- [Inter Core]
  - Affect values to enumeration giving the inter core service message ids
  - Shared memory settings shared between both cores
  - Add callback to register when NBU has unrecoverable Radio issue
- [NVM]
  - Add NV_STORAGE_MAX_SECTORS, NV_STORAGE_SIZE as linker symbol for alignment with other toolchain
  - ECC detection and recovery. New gNvSalvageFromEccFault_d and gNvVerifyReadBackAfterProgram_d compile flags. Please refer to ECC Fault detection section in README.md file located in NVM folder
- [OTA]
  - Prevent bus fault in case of ECC error when reading back OTA_CFR update status (disable by default)
- [SecLib]
  - Shared mutex for RNG and SecLib as they share same hardware resource
- [Key storage]
  - Fix to ignore the garbage at the end of buffers
  - Detect when buffers are too small in KS_AddKey() functions
- [FileCache]
  - Fix deadlock in Filecache FC_Process()
- [SDK]

  - Applications: remove definition of stack location and use default from linker script, fix warmboot stack in freertos at 0x20004000
  - Memory Manager Light:
    * fix Null pointer harfault when MEM_STATISTICS_INTERNAL enable
    * Fix MemReinitBank() on wakeup from lowpower when Ecc banks are turned off

6.1.7: KW45/K32W1 MR3

- [OTA]
  - New API OTA_SetNewImageFlagWithOffset()
  - Fix StorageBitmapSize calculation
  - OTA clean up: Removed OTA_ValidateImage()
- [Low Power]
  - New linker Symbol m_lowpower_flag_start in linker file.
    * Flag is used to indicate NBU that Application domain goes to power down mode. Keep this flag to 0 if only Deep sleep is supported
    * This flag will be set to 1 if Application domain goes to power down mode
  - Re-introduce PWR_AllowDeviceToSleep()/PWR_DisallowDeviceToSleep(), PWR_IsDeviceAllowedToSleep() API
  - Implement tick compensation mechanism for idle hook in a dedicated freertos utils file fwk_freertos_utils.[ch], new functions: FWK_PreIdleHookTickCompensation() and FWK_PostIdleHookTickCompensation
  - Rework timestamping on K4W1
    * PLATFORM_GetMaxTimeStamp() based on TSTMR
    * Rename PLATFORM_GetTimestamp() to PLATFORM_GetTimeStamp()
    * Update PLATFORM_Delay(): Rework to use TSTMR instead of LPTMR for platform_delay
    * Update PLATFORM_WaitTimeout(): Fixed a bug in PLATFORM_WaitTimeout() related to timer wrap
    * Add PLATFORM_IsTimeoutExpired() API
  - Fix race condition in PWR_EnterLowPower(), masking interrupts in case not done at upper layer
  - Low power timer split in new files fwk_platform_lowpower_timer.[ch]
  - New PWR_systicks_bm.c file for bare metal usage: implement SysTick suspend/resume functionality, New weak PWR_SysTicksLowPowerInit()
- [FRO32K]
  - Improve FRO32K calibration in NBU
  - create PLATFORM_InitFro32K() to initialize FRO32K instead of XTAL32K (to be called from hardware_init())
  - update FRO32K README.md file in SFC module
  - Debug:
  - Add Notification callback feature for SFC module FRO32K
  - Linker script update to support m_sfc_log_start in SMU2
- [SecLib]

  - Remove gSecLibSssUseEncryptedKeys_d compile option, split Secure/Unsecure APIs
  - RNG update to use same mutex than SecLib
  - Fix AES_128_CBC_Encrypt_And_Pad length
  - Implement RNG_ReInit() for lowpower
  - Fix issue in ECDH_P256_GenerateKeys() when waking up from power down
  - Call CRYPTO_ELEMU_reset() from SecLib_reInit() for power down support
- [BOARD]
  - Create new board_platform.h file for all Board characteristics settings (32Mhz XTAL, 32KHZ XTAL, etc..)
  - TM_EnterLowpower() TM_EnterLowpower() to be called from LP callbacks
  - Support Localization boards, Only BUTTON0 supported
    * New compile flag BOARD_LOCALIZATION_REVISION_SUPPORT
    * New pin_mux.[ch] files
  - Offer the possibility to override CDAC and ISEL 32MHz settings before the initialization of the crystal in board_platform.h
    * new BOARD_32MHZ_XTAL_CDAC_VALUE, BOARD_32MHZ_XTAL_ISEL_VALUE
    * BOARD_32MHZ_XTAL_TRIM_DEFAULT obsoleted
- [NVM file system]
  - Look ahead in pending save queue - Avoid consuming space to save outdated record
  - Fix NVM gNvDualImageSupport feature in NvIsRecordCopied
- [Inter Core]
  - Change PLATFORM_NbuApiReq() API return parameters granularity from uint32 to uint8
  - MAX_VARIANT_SZ change from 20 to 25
  - Set lp wakeup delay to 0 to reduce time of execution on host side, NBU waits XTAL to be ready before starting execution
  - Update inter core config rpmsg_config.h
  - Add timeout to while loops that relies on hardware in RemoteActiveReq(), Application can register Callbacks when timeout
  - Return non-0 status when calling PLATFORM_FwkSrvSendPacket when NBU non started
  - Let PLATFORM_GetNbuInfo return -10 if response not received on timeout - Doxygen platform_ics APIs
- [HW params]
  - New compile Macro for HW params placement in IFR - Save 8K in FLash: gHwParamsProdDataPlacement_c . 3 modes:
  - Legacy placement, move from legacy to IFR, IFR only placement
  - New compile Macro for Application data to be stored with HW params (in shared flash sector): gHwParamsAppFactoryDataExtension_d, New APIs:
    * Nv_WriteAppFactoryData(), Nv_GetAppFactoryData()
  - See HWParameter.h
- [Platform]

  - Implement PLATFORM_GetIeee802_15_4Addr() API in fwk_platform_ot.c - New gPlatformUseUniqueDeviceIdFor15_4Addr_d compile Macro
  - Wakeup NBU domain when reading RADIO_CTRL UID_LSB register in PLATFORM_GenerateNewBDAddr()
- [Reset]
  - New reset Implementations using Deep power down mode or LVD:
    * new files fwk_platform_reset.[ch]
    * new APIs: PLATFORM_ForceDeepPowerDownReset(), PLATFORM_ForceLvdReset() + reset on ext pins
    * new compile flags: gAppForceDeepPowerDownResetOnResetPinDet_d and gAppForceLvdResetOnResetPinDet_d to reset on external pins
- [FSCI]
  - fix when gFsciRxAck_c enabled
  - integrate new reset APIs

6.1.4: RW610/RW612 RFP1

- [Low Power]
  - Added support of low power for OpenThread stack.
  - Added PWR_AllowDeviceToSleep/PWR_DisallowDeviceToSleep/PWR_IsDeviceAllowedToSleep APIs.
- [platform]
  - Added PLATFORM_GetMaxTimeStamp API.
  - Fixed high impact Coverity.
- [FreeRTOS]
  - Created a new utilities module for FreeRTOS: fwk_freertos_utils.c/h.
  - Implemented a tick compensation mechanism to be used in FreeRTOS idle hook, likely around flash operations. This mechanism aims to estimate the number of ticks missed by FreeRTOS in case the interrupts are masked for a long time.

6.1.4: KW45/K32W1 MR2

- [Low power]
  - Powerdown mode tested and enabled on Low Power Reference Design applications
  - XTAL32K removal functionality using FRO32K, supported from NBU firmwares - limitation: Application domain supports Deep Sleep only (not power down)
  - NBU low power improvement: low power entry sequence improvement and system clock reduction to 16Mhz during WFI
  - Wake up time from cold boot, reset, power switch greatly improved. Device starts on FRO32K, switch to XTAL32K when ready if gBoardUseFro32k_d not set
  - Bug fixes:
    * Move PWR LowPower callback to PLATFORM layers
    * Fix wrong compensation of SysTicks
    * Reinit system clocks when exiting power down mode: BOARD_ExitPowerDownCb(), restore 96MHz clock is set before going to low power

        * Call Timermanager lowpower entry exit callbacks from PLATFORM_EnterLowPower()
        * Update PLATFORM_ShutdownRadio() function to force NBU for Deep power down mode
    - K32W1:
        * Support lowpower mode for 15.4 stacks
- [NVM]
    - New Compilation MACRO gNvDualImageSupport to support multiple firmware image with different register dataset
    - Change default configuration gNvStorageIncluded_d to 1, gNvFragmentation_Enabled_d to 1, gUnmirroredFeatureSet_d to TRUE
    - Some MISRA issues for this new configuration.
    - Remove deprecated functionality gNvUseFlexNVM_d
- [SecLib]
    - New NXP Ultrafast ecp256 security library:
        * New optimized API for ecdh DhKey/ecp256 key pair computation: Ecdh_ComputeDhKeyUltraFast(), ECP256_GenerateKeyPairUltraFast().
        * New macro gSecLibUseDspExtension_d.
        * Improved software version of Seclib with Ultrafast library for ECP256_LePointValid()
    - Bug fixes:
        * Share same mutex between Seclib and RNG to prevent concurrent access to S200
        * Optimized S200 re-initialization, restore ecdh key pair after power down
        * Fixed race condition when power down low power entry is aborted
        * Endianness function updates and clean up
- [OTA]
    - OTASupport improvements:
        * New API OTA_GetImgState(), OTA_UpdateImgState()
        * OTASupport and fwk_platform_extflash API updates for external flash: OTA_SelectExternalStoragePartition(), PLATFORM_IsExternalFlashSectorBlank(), PLATFORM_IsExternalFlashPageBlank(), PLATFORM_OtaGetOtaPartitionConfig()
        * Updated OtaExternalFlash.c, 2 new APIs in fwk_platform_extflash.c
        * Removed unused FLASH_op_type and FLASH_TransactionOpNode_t definitions from public API
        * Removed unused InternalFlash_EraseBlock() from OtaInternalFlash.c
- [NBU firmware]
    - Mechanism to set frequency constraint to controller from the host PLATFORM_SetNbuConstraintFrequency()
    - NbuInfo has one more digit in versionBuildNo field
- [Board]
    - Support Extflash low power mode, add BOARD_UninitExternalFlash(), PLATFORM_UninitExternalFlash(), PLATFORM_ReinitExternalFlash()

  - Support XTAL32K removal functionatity, use FRO32K instead by setting gBoardUseFro32k_d to 1 in board.h file
  - Support localization boards KW45B41Z-LOC Rev C
  - Low power improvement: New BOARD_InitPins() and BOARD_InitPinButtonBootConfig() called from hardware_init.c
  - Removed KW45_A0_SUPPORT support (dcdc)
  - Bug fixes:
    * Fixed glitches on the serial manager RX when exiting from power down
    * Fixed ADC not deinitialized in clock gated modes in BOARD_EnterLowPowerCb()
    * Fixed UART output flush when going to low power: BOARD_UninitAppConsole()
- [platform]
  - PLATFORM_InitBle(), PLATFORM_SendHci() can now block with timeout if NBU does not answer. Application can register callback function to be notified when it occurs: PLATFORM_RegisterBleErrorCallback()
  - Added API to set and get 32Khz XTAL capacitance values: PLATFORM_GetOscCap32KValue() and PLATFORM_SetOscCap32KValue()
  - Added new Service FWK call gFwkSrvNbuMemFullIndication_c to get NBU mem full indication, register with PLATFORM_RegisterNbuMemErrorCallback()
  - Added support negative value in platform intercore service
- [linker script]
  - Realigned gcc linker script with IAR linker script.
  - Added possibility to redefine cstack_start position
  - Added Possibility to change gNvmSectors in gcc linker script
  - Added dedicated reserved Section in shared memory for LL debugging
- [FreeRTOSConfig.h]
  - Removed unused MACRO configFRTOS_MEMORY_SCHEME and configTOTAL_HEAP_SIZE
- [HW Param]
  - Added xtalCap32K field to store XTAL32K triming value
- [fwk_hal_macros.h]
  - Added MACRO for KB, MB and set, clear bits in bit fields
- [Debug]
  - Added MACROs for performance measurement using DWT: DBG_PERF_MEAS

6.1.3 KW45 MR1 QP1

- [Initialization] Delay the switch to XTAL32K source clock until the BLE host stack is initialized
- [lowpower] NBU wakeup from lowpower: configuration can now be programmed with BOARD_NBU_WAKEUP_DELAY_LPO_CYCLE, BOARD_RADIO_DOMAIN_WAKE_UP_DELAY in board.h file
- [NBU firmware] Major fix for NBU system clock accuracy
- [clock_config]
  - Update SRAM margin and flash config when switching system frequency

  - Trim FIRC in HSRUN case
- [XTAL 32K trim] XTAL 32K configuration can be tuned in board.h file with BOARD_32MHZ_XTAL_TRIM_DEFAULT, BOARD_32KHZ_XTAL_CLOAD_DEFAULT, BOARD_32KHZ_XTAL_COARSE_ADJ_DEFAULT
- [MAC address] Add OUI field in PLATFORM_GenerateNewBDAddr() when using Unique Device Id

6.1.2: RW610/RW612 PRC1

- [Low Power]
  - Updates after SDK Power Manager files renaming.
  - Moved PWR LowPower callback to PLATFORM layers.
  - Bug fixes:
    * Fixed wrong compensation of SysTicks during tickless idle.
    * Reinit RTC bus clock after exit from PM3 (power down).
- [OTA]
  - Initial support for OTA using the external flash.
- [platform]
  - Implemented platform specific time stamp APIs over OSTIMER.
  - Implemented platform specific APIs for OTA and external flash support.
  - Removed PLATFORM_GetLowpowerMode API.
  - Added support of CPU2 wake up over Spinel for OpenThread stack.
  - Bug fixes:
    * Fixed issues related to handling CPU2 power state.
- [board]
  - Updated flash_config to support 64MB range.
- [linker script]
  - Fixed wrong assert.

6.1.1: KW45/K32W1 MR1

- [platform] Use new FLib_MemSet32Aligned() to write in ECC RAM bank to force ECC calculation in the MEM_ReinitRamBank() function
- [FunctionLib] Implement new API to set a word aligned
- [platform] Set coarse amplifier gain of the oscilattor 32k to 3
- [platform] Switch back to RNG for MAC Adress generation
- [SecLib] Get rid of the lowpower constraint of deep sleep in ECDH API
- [DCDC] Set DCDC output voltage to 1.35V in case LDO core is set to 1.1V to ensure a drop of 250mV between them
- [NVM] NvIdle() is now returning the number of operations that has been executed
- [documentation] Add markdown of each framework module by default on all package
- [LowPower] Add a delay advised by hardware team on exit of lowpower for SPC
- [SecLib] Rework of SecLib_mbedTLS ECDH functions

- [OTA] Make OTA_IsTransactionPending() public API
- [FunctionLib] Change prototype of FLib_MemCpyWord(), pDst is now a void* to permit more flexibility
- [NVM] Add an API to know if there is a pending operation in the queue
- [FSCI] Fix wrong error case handling in FSCI_Monitor()

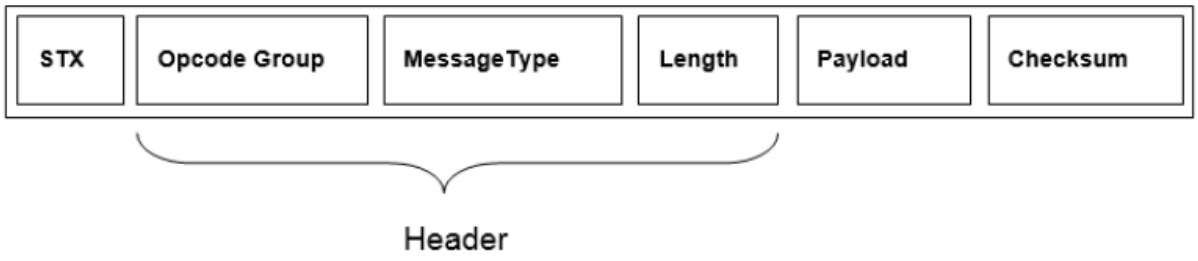
6.1.0: KW45/K32W1 RFP

- [LowPower] Do not call PLATFORM_StopWakeUpTimer() in PWR_EnterLowPower() if PLATFORM_StartWakeUpTimer() was not previously called
- [boards] Add the possibility to wakeup on UART 0 even if it is not the default UART
- [boards] Add support for Hardware flow control for UART0, Enable with gBoard-UseUart0HwFlowControl, Pin mux update with two additional API for RTS, CTS pins
- [Sensors] Improve ADC wakeup time from deep sleep state: use save and restore API for ADC context before/after deep sleep state.
- [linker script] update SMU2 shared memory region layout with NBU: increase sqram_btblebuf_size to support 24 connections. Shared memory region moved to the end
- [SecLib] SecLib_DeriveBluetoothSKD() API update to support if EdgeLock key shall be re-generated

6.0.11: KW45/K32W1 PRC3.1

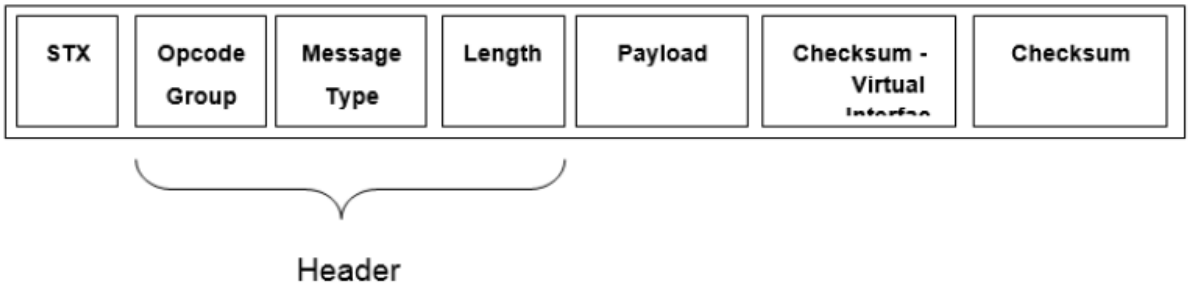
FSCI: Framework Serial Communication Interface Overview

The Framework Serial Communication Interface (FSCI) is both a software module and a protocol that allows monitoring and extensive testing of the protocol layers. It also allows separation of the protocol stack between two protocol layers in a two processing entities setup, the host processor (typically running the upper layers of a protocol stack) and the Black Box application (typically containing the lower layers of the stack, serving as a modem). The Test Tool software is an example of a host processor, which can interact with FSCI Black Boxes at various layers. In this setup, the user can run numerous commands to test the Black Box application services and interfaces.



The FSCI enables common service features for each device enables monitoring of specific interfaces and API calls. Additionally, the FSCI injects or calls specific events and commands into the interfaces between layers.

An entity which needs to be interfaced to the FSCI module can use the API to register opcodes to specific interfaces. After doing so, any packet coming from that interface with the same opcode triggers a callback execution. Two or more entities cannot register the same opcode on the same interface, but they can do so on different interfaces. For example, two MAC instances can register the same opcodes, one over UARTA, and the other over UARTB. This way, Test Tool can communicate with each MAC layer over two UART interfaces.



The FSCI module executes either in the context of the Serial Manager task or owns its dedicated task if the compilation Macro *gFsciUseDedicatedTask_c* is set to 1.

FSCI packet structure

The FSCI module sends and receives messages as shown in the figure below. This structure is not specific to a serial interface and is designed to offer the best communication reliability. The Black Box device expects messages in little-endian format. It also responds with messages in little-endian format.

Below is an illustration of the FSCI packet structure when a virtual interface is used instead :

Field name	Length (bytes)	Description
STX	1	Used for synchronization over the serial interface. The value is always 0x02.
Opcode Group	1	Distinguishes between different Service Access Primitives (for example MLME or MCPS).
Message Type	1	Specifies the exact message opcode that is contained in the packet.
Length	1 or 2	The length of the packet payload, excluding the header and FCS. The length field content must be provided in little-endian format.
Payload	variable	Payload of the actual message.
Checksum	1	Checksum field used to check the data integrity of the packet.
Checksum2	0 or 1	The second CRC field appears only for virtual interfaces.

NOTE : When virtual interfaces are used, the first checksum is decremented with the ID of the interface. The second checksum is used for error detection.

constant definition

The following Macro configurs the FSCI module

```
#define gFsciIncluded_c 0 /* Enable/Disable FSCI module */
#define gFsciUseDedicatedTask_c 1 /* Enable Fsci task to avoid recursivity in Fsci module (Misra␣
↪compliant) */
#define gFsciMaxOpGroups_c 8
#define gFsciMaxInterfaces_c 1
#define gFsciMaxVirtualInterfaces_c 0
#define gFsciMaxPayloadLen_c 245 /* bytes */
#define gFsciTimestampSize_c 0 /* bytes */
#define gFsciLenHas2Bytes_c 0 /* boolean */
#define gFsciUseEscapeSeq_c 0 /* boolean */
#define gFsciUseFmtLog_c 0 /* boolean */
#define gFsciUseFileDataLog_c 0 /* boolean */
#define gFsciLoggingInterface_c 1 /* [0..gFsciMaxInterfaces_c) */
#define gFsciHostMacSupport_c 0 /* Host support at MAC layer */
```

The following provides the OpGroups values reserved by MAC, application, and FSCI.

FSCI Host

FSCI Host is a functionality that allows separation at a certain stack layer between two entities, usually two boards running separate layers of a stack.

Support is provided for functionality at the MAC layer, for example, MAC/PHY layers of a stack are running as a Black Box on a board, and MAC higher layers are running on another. The higher layers send and receive serial commands to and from the MAC Black Box using the FSCI set of operation codes and groups.

The protocol of communication between the two is the same. The current level of support is provided for:

- FSCI_MsgResetCPUReqFunc – sends a CPU reset request to black box
- FSCI_MsgWriteExtendedAdrReqFunc – configures MAC extended address to the Black Box
- FSCI_MsgReadExtendedAdrReqFunc – N/A

The approach on the Host interfacing a Black Box using synchronous primitives is by default the polling of the FSCI_receivePacket function, until the response is received from the Black Box. The calling task polls whenever the task is being scheduled. This is required because a stack synchronous primitive requires that the response of that request is available in the context of the caller right after the SAP call has been executed.

The other option, available for RTOS environments, is using an event mechanism. The calling task blocks waiting for the event that is sent from the Serial Manager task when the response is available from the Black Box. This option is disabled by default. The disadvantage of this option is that the primitive cannot be received from another Black Box through a serial interface because the blocked task is the Serial Manager task, which reaches a deadlock as cannot be released again.

FSCI ACK

ACK transmission is enabled through the gFsciTxAck_c macro definition. Each FSCI valid packet received triggers an FSCI ACK packet transmission on the same FSCI interface that the packet was received on. The serial write call is performed synchronously to send the ACK packet before any other FSCI packet. Only then the registered handler is called to process the received packet. The ACK is represented by the gFSCI_CnfOpcodeGroup_c and mFsciMsgAck_c Opcode. An additional byte is left empty in the payload so that it can be used optionally as a packet identifier to correlate packets and ACKs. ACK reception is the other component that is enabled through gFsciRxAck_c. The behavior is such that every FSCI packet sent through a serial interface triggers an FSCI ACK packet reception on the same interface after the packet is sent. If an ACK packet is received, the transmission is considered successful. Otherwise, the packet is resent a number of times. The ACK wait period is configurable through mFsciRxAckTimeoutMs_c and the number of transmission retries through mFsciTxRetryCnt_c. The ACK mechanism described above can also be coupled with a FSCI packet reception timeout enabled through gFsciRxTimeout_c and configurable through mFsciRxRestartTimeoutMs_c. Whenever there are no more bytes to be read from a serial interface, a timeout is configured at the predefined value if no other bytes are received. If new bytes are received, the timer is stopped and eventually canceled at successful reception. However, if, for any reason, the timeout is triggered, the FSCI module considers that the current packet is invalid, drops it, and searches for a new start marker.

FSCI usage example

Detailed data types and APIs are described in ConnFWK API documentation.

Initialization

```
/* Configure the number of interfaces and virtual interfaces used */
#define gFsciMaxInterfaces_c 4
```

(continues on next page)

(continued from previous page)

```
#define gFsciMaxVirtualInterfaces_c 2
/* ... */
/* Define the interfaces used */
static const gFsciSerialConfig_t myFsciSerials[] = {
    /* Baudrate, interface type, channel No, virtual interface */ {gUARTBaudRate115200_c, gSerialMgrUart_
↪c, 1, 0}, {gUARTBaudRate115200_c, gSerialMgrUart_c, 1, 1}, {0 , gSerialMgrIICSlave_c, 1, 0}, {0 ,␣
↪gSerialMgrUSB_c, 0, 0},
};
/* ... */
/* Call init function to open all interfaces */
FSCI_Init( (void*)mFsciSerials );
```

Registering operation groups

```
myOpGroup = 0x12; // Operation Group used
myParam = NULL; // pointer to a parameter to be passed to the handler function (myHandlerFunc)
myInterface = 1; // index of entry from myFsciSerials
/* ... */
FSCI_RegisterOpGroup( myOpGroup, gFsciMonitorMode_c, myHandlerFunc, myParam, myInterface );
```

Implementing handler function

```
void fsciMcpsReqHandler(void *pData, void* param, uint32_t interfaceId)
{
    clientPacket_t *pClientPacket = ((clientPacket_t*)pData);
    fsciLen_t myNewLen;
    switch( pClientPacket->structured.header.opCode )
    {
        case 0x01:
        {
            /* Reuse packet received over the serial interface The OpCode remains the same. The length of the␣
↪response must be <= that the length of the received packet */
            pClientPacket->structured.header.opGroup = myResponseOpGroup;/* Process packet */
            /* ... */
            pClientPacket->structured.header. len = myNewLen;
            FSCI_transmitFormatedPacket(pClientPacket, interfaceId);
            return;
        }
        case 0x02:
        {
            /* Alocate a new message for the response. The received packet is Freed */
            clientPacket_t *pResponsePkt = MEM_BufferAlloc( sizeof(clientPacketHdr_t) + myPayloadSize_d␣
↪+ sizeof(uint8_t) // CRC);
            if(pResponsePkt)
            {
                /* Process received data and fill the response packet */
                pResponsePkt->structured.header. len = myPayloadSize_d;
                FSCI_transmitFormatedPacket(pClientPacket, interfaceId);
            }
            break;
        }
        default:
            MEM_BufferFree( pData );
            FSCI_Error( gFsciUnknownOpcode_c, interfaceId );
            return;
    }
    /* Free message received over the serial interface */
    MEM_BufferFree( pData );
}
```

Helper Functions Library Overview

This framework provides a collection of features commonly used in embedded software centered on memory manipulation.

HWParameter: Hardware parameter Production Data Storage

Hardware parameters provide production data storage

Overview

Different platforms/boards need board/network node-specific settings to function according to the design. (Examples of such settings are IEEE® addresses and radio calibration values specific to the node.) For this purpose, the last flash sector is reserved and contains hardware-specific parameters for production data storage. These parameters pertain to the network node as a distinct entity. For example, a silicon mounted on a PCB in a specific configuration, rather than to just the silicon itself. This sector is reserved by the linker file, through the PROD_DATA section and it should be read/written only through the API described below.

> Note : This sector is not erased/written at code download time and it is not updated via over-the-air firmware update procedures to preserve the respective node-specific data, regardless of the firmware running on it.

Constant Definitions

Name :

```
extern uint32_t PROD_DATA_BASE_ADDR[];
```

Description :

This symbol is defined in the linker script. It specifies the start address of the PROD_DATA section.

Name :

```
static const uint8_t mProdDataIdentifier[10] = {"PROD_DATA:"};
```

Description :

The value of this constant is copied as identification word (header) at the beginning of the PROD_DATA area and verified by the dedicated read function.

Note: the length of mProdDataIdentifier imposes the definition of PROD_DATA_ID_STRING_SZ as 10. The legacy HW parameters structure provides headroom for future usage. There are currently 63 bytes available.

Data type definitions

Name :

```
typedef PACKED_STRUCT HwParameters_tag
{
    uint8_t identificationWord[PROD_DATA_ID_STRING_SZ]; /* internal usage only: valid data present */
    /*@{*/
    uint8_t bluetooth_address[BLE_MAC_ADDR_SZ];      /*!< Bluetooth address */
    uint8_t ieee_802_15_4_address[IEEE_802_15_4_SZ]; /*!< IEEE 802.15.4 MAC address - K32W1 only␣
↪*/
    uint8_t xtalTrim;                                /*!< XTAL 32MHz Trim value */
    uint8_t xtalCap32K;                              /*!< XTAL 32kHz capacitance value */
    /* For forward compatibility additional fields may be added here
       Existing data in flash will not be compatible after modifying the hardwareParameters_t typedef.
```

(continues on next page)

(continued from previous page)

```
      In this case the size of the padding has to be adjusted.
    */
    uint8_t reserved[1];
    /* first byte of padding : actual size if 63 for legacy HwParameters but
      complement to 128 bytes in the new structure */
}
hardwareParameters_t;
```

Description:

Defines the structure of the hardware-dependent information.

> Note : Some members of this structure may be ignored on a specific board/silicon configuration. Also, new members may be added for implementation-specific purposes and the backward compatibility must be maintained.

The CRC calculation starts from the reserved field of the hardwareParameters_t and ends before the hardwareParamsCrc field. Additional members to this structure may be added using the following method :

Add new fields before the reserved field. This method does not cause a CRC fail, but you must keep in mind to subtract the total size of the new fields from the size of the reserved field. For example, if a field of uint8_t size is added using this method, the size of the reserved field shall be changed to 63.

Co-locating application factory data in HW Parameters flash sector.

The sector containing the Hardware parameter structure may be located in the internal flash, usually at its last sector. The actual Hardware parameter structure has a size of 128 bytes - including padding reserved for future use. Since there is plenty of room available in a flash sector (4kB or 8kB), co-locating Application Factory Data in the same structure prevents from reserving another flash sector for these data. The application designer may adopt this solution by defining gHwParamsAppFactoryDataExtension_d as 1. A total of 2kB is alloted to this purpose.

If this option was chosen, whenever any of the Hardware parameter fields is modified, its CRC16 will change so the sector will need erasing. The gHwParamsAppFactoryDataPreserveOnHwParamUpdate_d compilation option deals with restoring the contents of the App Factory Data. Nonetheless this requires a temporary allocation a 2kB buffer to preserve the previous content and restore then on completion of the Hw Parameter update.

Special reserved area at start of IFR1 in range [0x02002000..0x02002600[

On development boards a 1536 byte area is reserved and the actual Hardware parameter area begins at offset 0x600. Preserving this area on a HW parameter update also requires a temporary 1.5kB dynamic allocation (in addition to the App Factory 2kB allocation), to be able to restore on completion of update operation.

HW Parameters Production Data placement options

The placement of production data (PROD_DATA) can be selected based on the definition of gHwParamsProdDataPlacement_c (see fwk_config.h). The productions data seldom need update for final products, once calibration data, MAC addresses or others have been programmed. Two cases exist, plus a transition mode :

1) gHwParamsProdDataMainFlashMode_c (0) :
    - PROD_DATA are located at top of Main Flash. Hardware parameters section is placed in the last sector of internal flash [0xfe000..0x100000[.
    - The linker script must reserve this area explicitly so as to prevent placement of NVM or text sections at that location by setting gUseProdInfoMainFlash_d.

2) gHwParamsProdDataMainFlash2IfrMode_c(1) : - PROD_DATA are located in IFR1, but MainFlash version still exists during interim period. - If the contents of the PROD_DATA section in MainFlash is valid (not blank and correct CRC) but the IFR PROD_DATA is still blank, copy the contents of MainFlash PROD_DATA to IFR location. - When done PROD_DATA in IFR are used. Once the transition is done, an application using (2: gHwParamsProdDataPlacementIfrMode_c) may be programmed.

3) gHwParamsProdDataIfrMode_c (2) :

   - PROD_DATA section dwells in the IFR1 sector [0x02002000..0x02004000[
   - in development phase the area comprised between [0x02002000..0x02002600[must be reserved for internal purposes.
   - This allows to free up the top sector of Main Flash by linking with gUseProdInfoMainFlash_d unset.

Low Power Low power reference user guide

This Readme file describes the connectivity software architecture and provides the general low power enablement user guide.

Connectivity Low Power Software architecture

The connectivity low power software architecture is composed of various components. These are described from the lower layer to the application layer:

1. The SDK power manager in component/power_manager. This component provides the basic low power framework. It is not specific to the connectivity but generic across devices. It performs the following functions:
   - Gathers the low power constraints for upper layer and takes the decision on the best suitable low power state the device is allowed to go to fullfill the constraints.
   - Calls the low power entry and exit function callbacks.
   - Calls the appropriate SW routines to switch the device into the suitable low power state.
2. Connectivity Low power module in the connectivity framework. This module is composed of:
   - The low power service called PWR inside framework/LowPower (this folder), This module is generic to all connectivity devices.
   - The platform lowpower: fwk_platform_lowpower.[ch] located in framework\platform\<platform_name>. These files are a collection of low power routines functions for the PWR module and upper layer. These are specific to the device.

   Both PWR and platform lowpower files are detailed in the section below.
3. Low power Application modules, which consists of three parts:
   - Application initialization file app_services_init.c where the application initializes the low power framework. See the next section 'Demo example for typical usage of low power framework'.
   - Application Idle task from application to call the main low power entry function PWR_EnterLowPower() to switch the device into low power. This function is application specific, one example is given in the section 1.3.3.
   - Low power board files : board_lp.[ch] located in board/lowpower. These files implement the low power entry and exit functions related to the application and board. Users must modify these files for their own needs. Example code is given for the connectivity applications.

User guide is provided in section 1.3 below.

Note : Linker script may also be impacted for power down mode support in order to provide an RAM area for ROM warm boot (depends on the platform) and application warmboot stack

The Low power central and master reference design applications provide an example of Low power implementation for BLE. Customer can also refer to the associated document 'low power connectivity reference design user guide'.

1.1 - SDK power manager

This module provides the main low power functionalities such as:

- Decide the best low-power mode dependent on the constraints set by upper layers by using PWR_SetLowPowerModeConstraints() API function.
- Handle the sequences to enter and exit low-power mode.
- Enable and configure wake up sources, call the application callbacks on low power entry/exit sequences.

The SDK power manager provides the capability for application and all components to receive low power constraints to the power. The Application does not set the low-power mode the device shall go into. When going to low power, the SDK power manager selects the best low-power mode that fits all the constraints.

As an example, if the low power constraint set from Application is Power Down mode, and no other constraint is set, the SDK power manager selects Power down mode, the next time the device enters low power. However, if a new constraint is set by another component, such as the SecLib module that operates Hardware encryption, the SecLib module would select WFI as additional low power constraint. Also, the SDK power manager selects this last low-power mode until the constraint is released by the SecLib module. It then reselects Power Down mode for further low power entry modes.

1.2 - PWR Low power module

The PWR module in the connectivity framework provides additional services for the connectivity stacks and applications on top of the SDK power manager.

It also provides a simple API for Connectivity Stack and Connectivity applications.

However, more advanced features such as configuring the wake-up sources are only accessible from the SDK Power Manager API.

In addition to the SDK Power Manager, the PWR module uses the software resources from lower level drivers but is independent of the platform used.

1.2.1 - Functional description

Initialization of the PWR module should be done through the $\mathrm{PWR\_Init()}$ function. This is mainly to initialize the SDK Power Manager and the platform for low power. It also registers the PWR low power entry or exit callback function $\mathrm{PWR\_LowpowerCb()}$ to the SDK Power Manager. This function is called back while entering and exiting the low power modes to perform mandatory save or restore operations for connectivity stacks. The application can perform extra optional save/restore operations in the $\mathrm{board\_lp}$ file where it can register to the SDK Power Manager its own callback. This method is usually used to handle optional peripherals such as serial interfaces, GPIOs, and so on.The main entry function is $\mathrm{PWR\_EnterLowPower()}$. It must be called from Idle task when no SW activity is required. The maximum duration for low power is given as argument $\mathrm{timeoutUs}$ in microseconds. This function checks the next Hardware event in the connectivity stack, typically the next Radio activity. A wakeup timer is programmed if the $\mathrm{timeoutUs}$ value is shorter than the next radio event timing. Passing a timeout of $\mathrm{0us}$ is interpreted as no timeout on the application side.

On device wakeup from low power state, the function returns the time duration the device has been in low power state.

Two APIs are provided to set and release low power state constraints: PWR_SetLowPowerModeConstraint() and PWR_ReleaseLowPowerModeConstraint(). These are helper functions. Users can use the SDK power manager directly if needed.

The PWR module also provides some API to be set as callbacks into other components to prevent from going to low power state. It can be used in following examples :

1. If a DMA is running, the module in charge of the DMA would need to set a constraint to avoid the system from going to a low power state when the RAM and system bus are no longer available.
2. If transfer is going on a peripheral, the drivers shall set a constraint to forbid low power mode.
3. If encryption is on going through an Hardware accelerator, the HW accelerator and the required ressources (clocks, etc), shall be kept active also by setting a constraints.

1.2.2 - Tickless mode support

This module also provides some routines functions PWR_SysticksPreProcess() and PWR_SysticksPostProcess() from PWR_systicks.c in order to support the tickless mode when using FreeRTOS. The tickless mode is the capability to suspend the periodic system ticks from FreeRTOS and keep timebase tracking using another low power counter. In this implementation, the Timer Manager and time_stamp component are used for this purpose.

Idle task shall call these functions PWR_SysticksPreProcess() and PWR_SysticksPostProcess()‘ before and after the call to the main low power entry function PWR_EnterLowPower().

Refer to the *framework/LowPower/PWR_systicks.c* file or Section 2.1 below for more information.

1.3 - Low power platform submodule

Low power platform module file fwk_platform_lowpower.c provides the necessary helper functions to support low power device initialization, device entry, and exit routines. These are platform and device specific. Typically, the PWR module uses the low power platform submodule for all low power specific routines.

The low power platform submodule is documented in the Connectivity Framework Reference Manual document and in the Connectivity Framework API document.

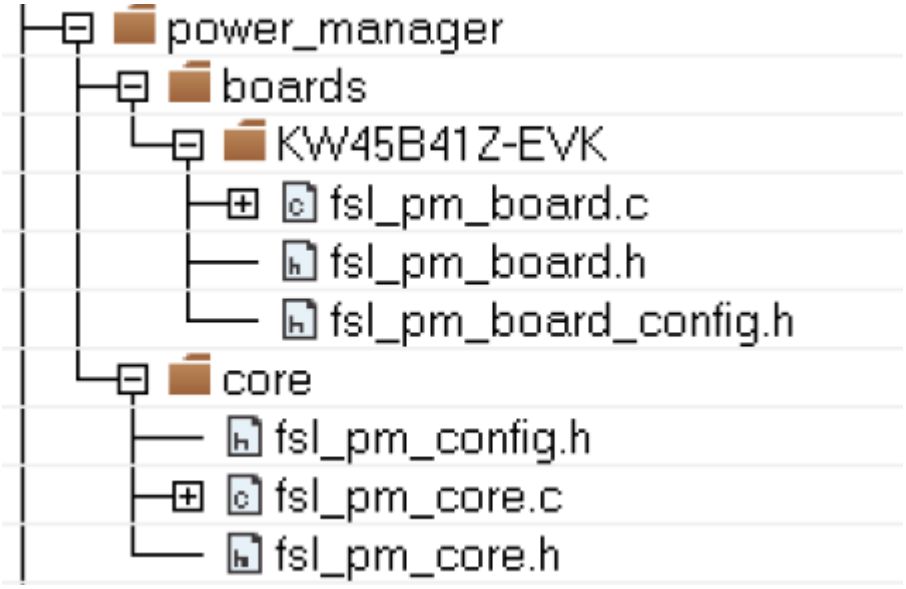
1.4 - Low power board files

Low power board files board_lp.[ch] are both application and board specific. Users should update this file to add new functions to include new used peripherals that require low power support. In the current SDK package, only Serial Manager over UART and button (IO toggle wake up source) are supported and demonstrated in the Bluetooth LE demo application.

Other peripherals that require specific action on low power entry and restore on low power exit should be added to low power board files. For more details, refer to section Low power board file update

2 - Low power Application user guide

This section provides a user guide to enable Low power on a connectivity application, It gives example of typical implementation for the initialization, Idle task function and low power entry/exit functions.

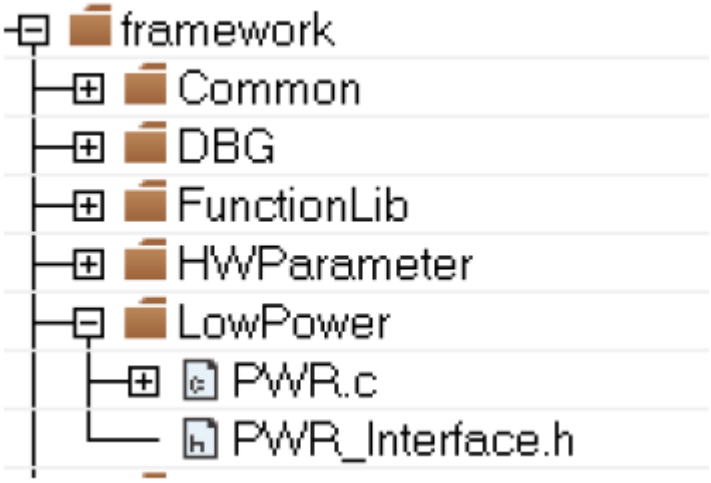


2.1 - Application Project updates

It is recommended to reuse the low-power peripheral/central reference design application projects as a start. This ensures that everything is in place for the low-power optimization feature. Then, application files may be added to one of the two projects.

However, users can start directly from the application project and implement low power in it, by performing the steps described in the following sections.

2.1.1 - SDK Power Manager

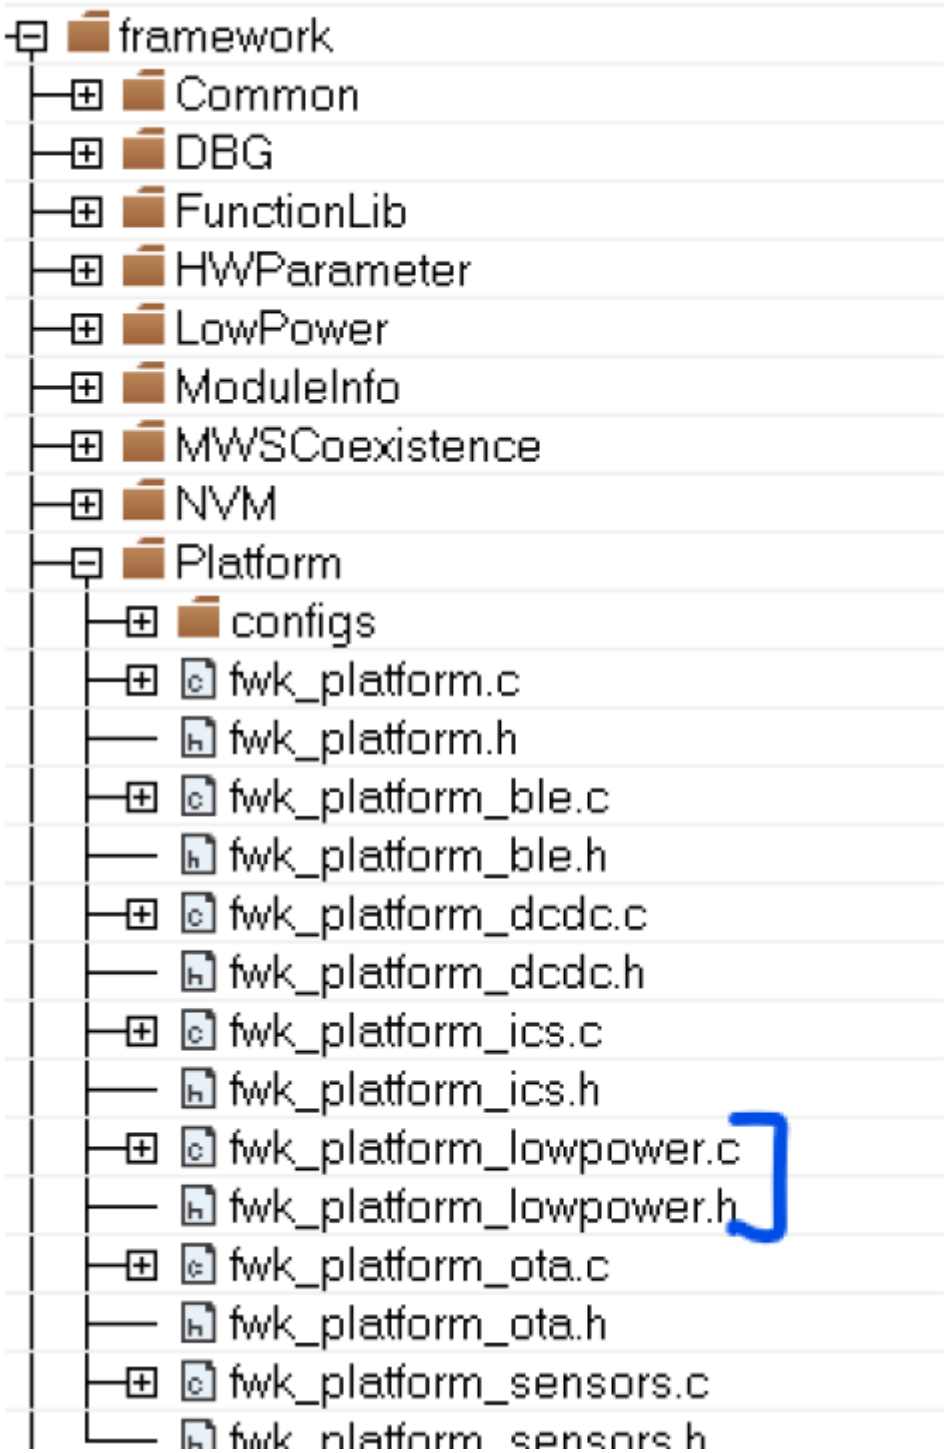


Most of the Low power functionality is implemented in the SDK Power Manager. The files to add into the project SDK power_manager module are listed in the figure below:

You need to use the files located in the folder that match your device.

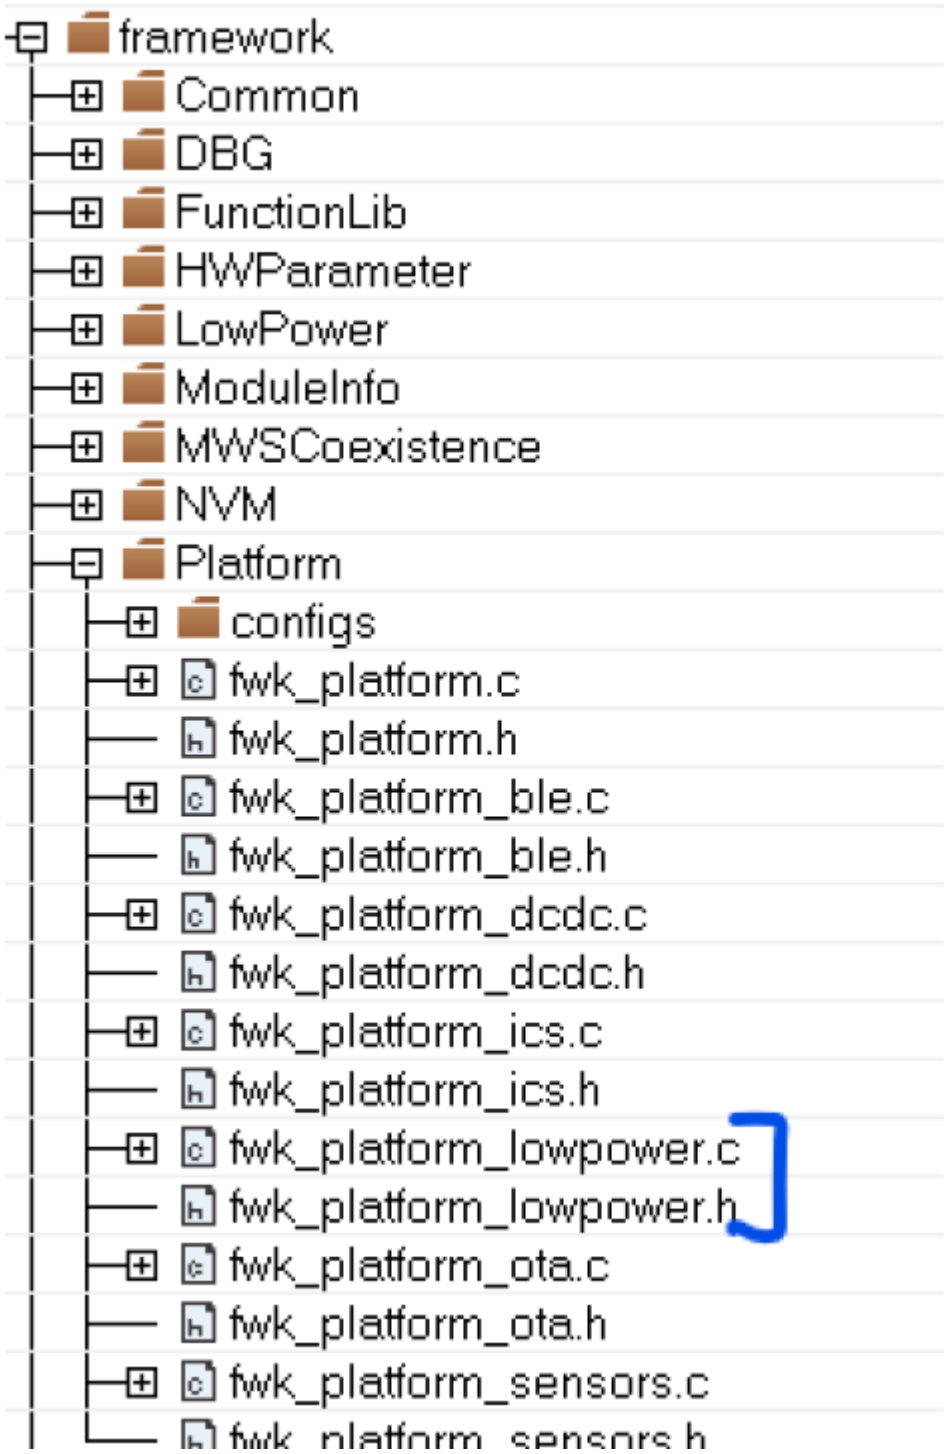
2.1.2 - PWR connectivity framework module

PWR.c PWR_Interface.h shall be added to your application projects :



Optionally, in order to support Systick less mode, PWR_systicks.c or PWR_systicks_bm.c could also be added.

The include path to add is: middleware/wireless/framework/LowPower



2.1.3 -Low power platform submodule

Low power platform files can be found in the 'Platform' module in the connectivity framework:

2.1.4 - Low power board files

These files are located in the same folder that the other board files board.[ch]. Hence, it is not required to add any new include path at compiler command line.

2.1.5 - Application RTOS Idle hook and tickeless hook functions

See section 2.4.3 Idle task implementation example

2.2 - Low power and wake up sources Initialization

Low power initialization and configuration are performed in APP_ServiceInitLowpower()function. This is called from APP_InitServices() function called from the main() function so all is already set up when calling the main application entry point, typically BluetoothLEHost_AppInit() function in the Bluetooth LE demo applications.

The default Low Power mode configured in APP_InitServices() is Deep Sleep mode. In Bluetooth

LE, (or any other stack technology), Deep Sleep mode fits for all use cases. For instance, for Bluetooth LE states: Advertising, Connected, Scanning states. This mode already performs a very good level of power saving and likely, this is not required to optimize more if the device is powered from external supply.

APP_ServiceInitLowpower() function performs the following initialization and configuration:

- Initialize the Connectivity framework Low power module PWR_Init(), this function initialized the SDK Power Manager.
- Configure the wakeup sources such as serial manager wake up source for UART, or button for IO wake up configuration. These are typical wakeup sources used in the connectivity application. Developer may want to add additional wake up sources here specific for the application.

  Note : The low power timer wakeup source and wakeup from Radio domain are directly enabled from the Connectivity framework Low power module PWR as it is mandatory for the connectivity stack. If your application supports other peripherals (such as i2c, spi, and others) that require wake sources from low power, developer should add additional wake up sources setting in this function APP_ServiceInitLowpower(). The complete list of wakeup sources are available from the SDK Power Manager component, see file fsl_pm_board.h in component/boards/<device_name>/.
- Initialize and register the Low power board file used to register and implement low power entry and exit callback function used for peripheral. This is done by calling the BOARD_LowPowerInit() function.
- Register low power Enter and exit critical function to driver component to enable / disable low power when the Hardware is active. Example is given for serial manager that needs to disable low power when the TX ring buffer contains data so the device does not enter low power until the buffer is empty.

Finally, APP_ServiceInitLowpower() function configures the Deep Sleep mode as the default low power constraint for the application. It is recommended to keep this level of low power constraint during all the connectivity stack initialization.

Example of low power framework initialization can be found in app_services_init.c file. Below is some code example for initializing the low power framework and wake up sources:

```
static void APP_ServiceInitLowpower(void)
{
    PWR_ReturnStatus_t status = PWR_Success;

    /* It is required to initialize PWR module so the application
     * can call PWR API during its init (wake up sources...) */
    PWR_Init();

    /* Initialize board_lp module, likely to register the enter/exit
     * low power callback to Power Manager */
    BOARD_LowPowerInit();

    /* Set Deep Sleep constraint by default (works for All application)
     *   Application will be allowed to release the Deep Sleep constraint
     *   and set a deepest lowpower mode constraint such as Power down if it needs
     *   more optimization */
    status = PWR_SetLowPowerModeConstraint(PWR_DeepSleep);
    assert(status == PWR_Success);

#if (defined(gAppButtonCnt_c) && (gAppButtonCnt_c > 0))

    /* Init and enable button0 as wake up source
     * BOARD_WAKEUP_SOURCE_BUTTON0 can be customized based on board configuration
```

(continues on next page)

(continued from previous page)

```
    * On EVK we use the SW2 mapped to GPIOD */
   PM_InitWakeupSource(&button0WakeUpSource, BOARD_WAKEUP_SOURCE_BUTTON0, NULL,␣
↪true);
#endif

#if (gAppButtonCnt_c > 1)
   /* Init and enable button1 as wake up source
    * BOARD_WAKEUP_SOURCE_BUTTON1 can be customized based on board configuration
    * On EVK we use the SW3 mapped to PTC6 */
   PM_InitWakeupSource(&button1WakeUpSource, BOARD_WAKEUP_SOURCE_BUTTON1, NULL,␣
↪true);
#endif

#if (defined(gAppUseSerialManager_c) && (gAppUseSerialManager_c > 0))

#if defined(gAppLpuart0WakeUpSourceEnable_d) && (gAppLpuart0WakeUpSourceEnable_d > 0)
   /* To be able to wake up from LPUART0, we need to keep the FRO6M running
    * also, we need to keep the WAKE domain is SLEEP.
    * We can't put the WAKE domain in DEEP SLEEP because the LPUART0 is not mapped
    * to the WUU as wake up source */
   (void)PM_SetConstraints(PM_LP_STATE_NO_CONSTRAINT, APP_LPUART0_WAKEUP_
↪CONSTRAINTS);
#endif

   /* Register PWR functions into SerialManager module in order to disable device lowpower
      during SerialManager processing. Typically, allow only WFI instruction when
      uart data are processed by serail manager  */
   SerialManager_SetLowpowerCriticalCb(&gSerMgr_LowpowerCriticalCBs);
#endif

#if defined(gAppUseSensors_d) && (gAppUseSensors_d > 0)
   Sensors_SetLowpowerCriticalCb(&app_LowpowerSensorsCriticalCBs);
#endif

   (void)status;
}
```

2.3 - low power entry/exit sequences : board files updates

Board Files that handles low-power are board_lp.[ch] files.

Low power board files implement the low-power callbacks of the peripherals to be notified when entering or exiting Low Power mode. This module also registers these low-power callbacks to the SDK Power Manager component to get the notifications when the device is about to enter low-power or exit Low Power mode. The Low-power callbacks are registered from BOARD_LowPowerInit() function. This function is called from app_services_init.c file after PWR module initialization.

The low power callback functions can be categorized in two groups:

- Entry Low power call back functions: These are usually used to prepare the peripherals to enter low-power. For example, they can be used for flushing FIFOs, switching off some clocks, and reconfiguring pin mux to avoid leakage on pins. In case of Power Down mode, these functions could be used to save the Hardware peripheral context.
- Exit Low power call back functions: These are typically used to restore the peripherals to functionality. Therefore, they perform the reverse of what is done by the entry callback functions: restoring the pin mux, re-enabling the clock, in case of Power Down mode, restoring the Hardware peripheral context, and so on.

Note that distinction can be done between clock gating mode (Deep Sleep mode), and power gated mode (Power down mode) when entering and exiting Low Power mode. The

BOARD_EnterLowPowerCb() and BOARD_ExitLowPowerCb() functions provide the code to call the various peripheral entry and exit functions to go and exit Deep Sleep mode: serial manager, button, debug console, and others.

However, the processing to save and restore the Hardware peripheral is implemented in different functions BOARD_EnterPowerDownCb() and BOARD_ExitPowerDownCb(). These two functions must be called when exiting the power gated modes of the power domain. These two should implement specific code for such case (likely the complete reinitialization of each peripheral). In order to know the Low Power mode that the wake up domain, or main domain has been entered, the low-power platform API PLATFORM_GetLowpowerMode() can be called.

> **Note :** The BOARD_ExitPowerDownCb() API is called before BOARD_ExitLowPowerCb() as it is generally required to restore the Hardware peripheral contexts before reconfiguring the pin mux to avoid any signal glitches on the pads.

Also, it is important to know whether the location of the hardware peripheral is in the main domain or wake up domain. The two power domains can go into different power modes with the limitation that the wakeup domain cannot go to a deepest Low Power mode than the main domain. Depending on the constraint set on SDK Power Manager, the wake up domain could remain in active while the main domain can go to deep sleep or power down modes. In this case, the peripherals in the wake up domain does not required to be restored, as explained in the **Power Down** section. Likely, only pin mux reconfiguration is required in this case.

Example The Low power entry and exit functions must be registered with the SDK Power Manager so that these functions are called when the device enters and exits low power mode. This is done by BOARD_LowPowerInit() typically called from the application source code in the app_services_init.c file.

```
static pm_notify_element_t boardLpNotifyGroup = {
    .notifyCallback = BOARD_LowpowerCb,
    .data           = NULL,
};

void BOARD_LowPowerInit(void)
{
    status_t status;

    status = PM_RegisterNotify(kPM_NotifyGroup2, &boardLpNotifyGroup);
    assert(status == kStatus_Success);
    (void)status;
}
```

The BOARD_LowpowerCb() callback function handles both the entry and exit sequences. An argument is passed to the function to indicate the low power state the device enters or exits. A typical implementation is given below. Users must ensure to differentiate low power entry and exit, and the various low power states.

Typically, nothing is expected to be done if low power state is WFI or Sleep mode. These modes are some light low power states and the system can be woken up by interrupt trigger.

In Deep sleep mode, the clock tree and the source clocks are off, and the system needs to be woken up from an event from the WUU module.

In Power down mode, some peripherals are likely to be powered off, context save and restore may need to be done in these functions.

```
static status_t BOARD_LowpowerCb(pm_event_type_t eventType, uint8_t powerState, void *data)
{
    status_t ret = kStatus_Success;
    if (powerState < PLATFORM_DEEP_SLEEP_STATE)
    {
        /* Nothing to do when entering WFI or Sleep low power state
```

(continues on next page)

(continued from previous page)

```
            NVIC fully functionnal to trigger upcoming interrupts */
    }
    else
    {
        if (eventType == kPM_EventEnteringSleep)
        {
            BOARD_EnterLowPowerCb();

            if (powerState >= PLATFORM_POWER_DOWN_STATE)
            {
                /* Power gated low power modes often require extra specific
                 * entry/exit low power procedures, those should be implemented
                 * in the following BOARD API */
                BOARD_EnterPowerDownCb();
            }
        }
        else
        {
            /* Check if Main power domain domain really went to Power down,
             *   powerState variable is just an indication, Lowpower mode could have been skipped by an␣
↪immediate wakeup
             */
            PLATFORM_PowerDomainState_t main_pd_state = PLATFORM_NO_LOWPOWER;
            PLATFORM_status_t           status;

            status = PLATFORM_GetLowpowerMode(PLATFORM_MainDomain, &main_pd_state);
            assert(status == PLATFORM_Successful);
            (void)status;

            if (main_pd_state == PLATFORM_POWER_DOWN_MODE)
            {
                /* Process wake up from power down mode on Main domain
                 *  Note that Wake up domain has not been in power down mode */
                BOARD_ExitPowerDownCb();
            }

            BOARD_ExitLowPowerCb();
        }
    }
    return ret;
}
```

2.4 - Low power constraint updates and optimization

Except for the board file update as seen in previous section, the application does not need any other changes for low-power support in Deep Sleep mode. It shall work as if no low-power is supported. However, If more aggressive power saving is required, this constraint can be changed in your application in order to further reduce the power consumption in Low Power mode.

2.4.1 - Changing the Default Application low power constraint after firmware initialization

The Low power reference design applications (central or peripheral) provides demonstration on how to change the Application low power constraint. In the Application main entry point BluetoothLEHost_AppInit(), Deep Sleep mode is configured by default from APP_ServiceInitLowpower() function.

> **Note :** It is recommended to keep Deep Sleep mode as default during all the stack initialization phase until BluetoothLEHost_Initialized() and BleApp_StartInit() functions are called. In case of Bonded device with privacy, it is recommended to wait for gControllerPrivacyStateChanged_c event to be called.

The BleApp_LowpowerInit() function provides an example of code on how to release the default Deep sleep low-power constraint and set a new constraint such as Power down mode for the application. This deeper low-power mode is used when no Bluetooth LE activity is ongoing, and if no other higher Low-power constraint is set by another component or layer. For instance, if some serial transmission is ongoing by the serial manager, or if the SecLib module has on going activity on the HW crypto accelerator, the low-power mode could be less deep.

```
static void BleApp_LowpowerInit(void)
{
#if defined(gAppLowpowerEnabled_d) && (gAppLowpowerEnabled_d>0)
    PWR_ReturnStatus_t status;

    /*
     * Optionally, Allow now Deepest lowpower mode constraint given by gAPP_
↪LowPowerConstraintInNoBleActivity_c
     *    rather than DeepSleep mode.
     * Deep Sleep mode constraint has been set in APP_InitServices(), this is fine
     *    to keep this constraint for typical lowpower application but we want the
     *    lowpower reference design application to be more agressive in term of power saving.

     *   To apply a lower lowpower mode than Deep Sleep mode, we need to
     *    - 1) First, release the Deep sleep mode constraint previously set  by default in app_services_init()
     *    - 2) Apply new lowpower constraint when No BLE activity
     *   In the various BLE states (advertising, scanning, connected mode), a new Lowpower
     *    mode constraint will be applied depending of Application Compilation macro set in app_preinclude.
↪h :
     *    gAppPowerDownInAdvertising, gAppPowerDownInConnected, gAppPowerDownInScanning
     */

    /*  1) Release the Deep sleep mode constraint previously set  by default in app_services_init() */
    status = PWR_ReleaseLowPowerModeConstraint(PWR_DeepSleep);
    assert(status == PWR_Success);
    (void)status;

    /*  2) Apply new Lowpower mode constraint gAppLowPowerConstraintInNoBleActivity_c *
     *      The BleAppStart() call above has already set up the new lowpower constraint
     *       when Advertising request has been sent to controller        */
    BleApp_SetLowPowerModeConstraint(gAppLowPowerConstraintInNoBleActivity_c);
#endif
}
```

2.4.2 - Changing the Application lowest low power constraint during application execution

In the various application use cases, (in the various Bluetooth LE activity states, advertising, connected, scanning), some lower low-power constraint can be set, as Power down for advertising, Deep Sleep for connected, or Scanning. Customer can change the level of Low Power mode in the various use case mainly depending of the time duration the device is supposed to remain in low-power. The longer the time that the device remains in low power, the higher the benefit for a deeper Low Power mode such as Power down mode. However, please note that the wake up from power down mode takes significantly more time than deep sleep as ROM code is re executed and the hardware logic needs to be restored. Sections Deep Sleep and Power Down provide some guidance on when to use Deep Sleep mode or Power Down modes respectively.

In the low power reference design applications, four application compilations macros are defined to adjust the low power mode into advertising, scanning, connected, or no Bluetooth LE activity. Other use cases can be added as desired. For instance, If application needs to run a DMA transfer, or if application needs to wakeup regularly to process data from external device, it may be useful to set WFI constraint (in case of DMA transfer), or Deep Sleep constraint (in case of regular wake up to process external data), rather than power down or a even lower low-power mode.

The four application compilation macros can be found in app_preinclude.h file of the project. See

app_preinclude.h for low power reference design peripheral application:

```
/*! Lowpower Constraint setting for various BLE states (Advertising, Scanning, and Connected mode)
   The value shall map with the type defintion PWR_LowpowerMode_t in PWR_Interface.h
     0 : no LowPower, WFI only
     1 : Reserved
     2 : Deep Sleep
     3 : Power Down
     4 : Deep Power Down
   Note that if a Bluetooth LE State is configured to Power Down mode, you must ensure that the
     gLowpowerPowerDownEnable_d variable is set to 1 in the Linker Script.
   The PowerDown mode allows lowest power consumption but the wake-up time is longer and the first 16K␣
↪in SRAM is reserved to ROM code (this section will be corrupted on       each power down wake-up so␣
↪only temporary data could be stored there.)
       Power down feature not supported. */

#define gAppLowPowerConstraintInAdvertising_c`         3
/* Scanning not supported on peripheral */
//#define gAppLowPowerConstraintInScanning_c           2
#define gAppLowPowerConstraintInConnected_c            2
#define gAppLowPowerConstraintInNoBleActivity_c        4
```

In lowpower_central.c and the lowpower_preripheral.c files, the application sets and releases the low power constraint from BleApp_SetLowPowerModeConstraint() and BleApp_ReleaseLowPowerModeConstraint() functions. These functions are called with the macro value passed as argument.

> **Important Note :** Setting the application low power constraint must be done on new Bluetooth LE state request so the new constraint is applied immediately. In contrast, the application low-power mode constraint must be released when the Bluetooth LE state is exited. For example, setting the new low power constraint for Advertising must be done when the application requests advertising to start. Releasing the low power constraint must be done in the advertising stop callback (advertising has been stopped).

After releasing the low power constraint, the previous low power constraint, (likely the one that has been set during firmware initialization in APP_ServiceInitLowpower() function, or the updated low power constraint in BleApp_StartInit() function) applies again.

2.4.3 - Idle task implementation example

2.4.3.1 Tickless mode support and Low power entry function

Idle task configuration from FreeRTOS must be enabled by using the parameter configUSE_TICKLESS_IDLE in FreeRTOSConfig.h. This has the effect to have vPortSuppressTicksAndSleep() called from Idle task created by FreeRTOS. Here is a typical implementation of this function:

```
void vPortSuppressTicksAndSleep(TickType_t xExpectedIdleTime)
{

    bool abortIdle = false;
    uint64_t actualIdleTimeUs, expectedIdleTimeUs;

    /* The OSA_InterruptDisable() API will prevent us to wakeup so we use
     * OSA_DisableIRQGlobal() */
    OSA_DisableIRQGlobal();

    /* Disable and prepare systicks for low power */
    abortIdle = PWR_SysticksPreProcess((uint32_t)xExpectedIdleTime, &expectedIdleTimeUs);
```

(continues on next page)

(continued from previous page)

```
    if (abortIdle == false)
    {
        /* Enter low power with a maximal timeout */
        actualIdleTimeUs = PWR_EnterLowPower(expectedIdleTimeUs);

        /* Re enable systicks and compensate systick timebase */
        PWR_SysticksPostProcess(expectedIdleTimeUs, actualIdleTimeUs);
    }

    /* Exit from critical section */
    OSA_EnableIRQGlobal();
}
```

2.4.3.2 Connectivity background tasks and Idle hook function example

A few processes need to be run in the background before going into low power. This is the case for writing in NVM, or firmware update OTA to be writen in Flash. If so, configUSE_IDLE_HOOK must be enabled in FreeRTOSCOnfig.h. This enables vApplicationIdleHook() to be called prior to vPortSuppressTicksAndSleep(). Typical implementation of vApplicationIdleHook() function can be found here :

```
void vApplicationIdleHook(void)
{
    /* call some background tasks required by connectivity */
#if ((gAppUseNvm_d) || \
    (defined gAppOtaASyncFlashTransactions_c && (gAppOtaASyncFlashTransactions_c > 0)))

    if (PLATFORM_CheckNextBleConnectivityActivity() == true)
    {
        BluetoothLEHost_ProcessIdleTask();
    }
#endif
}
```

PLATFORM_CheckNextBleConnectivityActivity() function implemented in low power platform file fwk_platform_lowpower.c typically checks the next connectivity event and returns true if there is enough time to perform time consuming tasks such as flash erase/write operations (These operations can be defined by the compile macro depending on the platform).

2. Low power features

2.1 - FreeRTOS systicks

Low power module in the framework supports the systick generation for FreeRTOS. Systicks in FreeRTOS are generally not required in the Bluetooth LE demos applications. The framework already supports timers through the timer manager component, so the application can use the timers from this module. The systicks in FreeRTOS are useful for all internal timer service provided by FreeRTOS (through OSA) such as OSA_TimeDelay(), OSA_TimeGetMsec(), OSA_EventWait(). When systicks are enabled, an interrupt (systick interrupt) is triggered and executed on a periodic basis. In order to save power, periodic systick interrupts are undesirable and thus disabled when going to low-power mode. This feature is called low power FreeRTOS tickless mode. When entering the low power state, the system ticks must be disabled and switch to a low power timer. On wake-up, the module retrieves the time passed in low power and compensates the ticks count accordingly. This feature does not apply on bare metal scheduler.

On FreeRTOS, the vPortSuppressTicksAndSleep() function implemented in the app_low_power.c file is called when going to idle state. FreeRTOS provides to this function the xExpectedIdleTime, which is the time in tick periods before a task is due to be moved into the Ready state. This function manages the systicks (disable/enable) through PWR_SysticksPreProcess() and

PWR_SysticksPostProcess() calls. Then, when calling PWR_EnterLowPower(), a time out duration in micro seconds is given and the function sets a timer before entering low power. In addition, this function returns the low power period duration, used to compensate the ticks count.

In our example low power reference design peripheral application, a function OSA_EventWait() has been added to demonstrate the tickless mode feature. You can adjust the timeout with the gAppTaskWaitTimeout_ms_c flag in the app_preinclude.h file, its value in our demo is 8000ms. So 8 seconds after stopping any activity we will wake up from low power. If the flag is not defined in the application, its value is osaWaitForever_c and there will be no OS wake up.

2.2 - Selective RAM bank retention

To optimize the consumption in low power, the linker script specific function PLATFORM_GetDefaultRamBanksRetained() is implemented. This function obtains the RAM banks that need to be retained when the device goes in low power, in order to set them with PLATFORM_SetRamBanksRetained() function. The RAM banks that are not needed are set in power off state, when the device goes in low power mode.

The function PLATFORM_GetDefaultRamBanksRetained() is linker script specific. Hence, it cannot be adapted for a different application. If these functions are called from the board_lp.c, it is possible to give to PLATFORM_SetRamBanksRetained() a different bank_mask adapted to your specific application.

In deep power down mode, this feature does not have any impact because in this power mode, all RAM banks are already powered off.

3 - Low power modes overview

PWR module API provides the capability to set low power mode constraints from various components or from the application. These constraints are provided to the SDK Power Manager. Upper layer (such as all Application code, connectivity stacks) can call directly the SDK Power Manger if it requires more advanced tuning. The PWR API can be found in PWR_Interface.h.

> **Note :** 'Upper layer' signifies all layers, applications, components, or modules that are above the connectivity framework in the Software architecture.
>
> **Note :** Each power domain has its own low power mode capability. The low power modes described below are for the main domain and it is supposed that the wake up domain goes to the same low power mode. This is not always true as the wake up domain that contains some wake up peripheral can go to a lower low power mode state than the main domain so the peripherals in the wake up domain can remain operational when the main domain is in low power mode (deep sleep or power down modes). In this case, the context of the Hardware peripheral located in the wake up domain does not need to be saved and restored as for the peripherals located in the main domain

3.1 Wait for Interrupt (WFI)

Definition

In the Wait for Interrupt (WFI) state, the CPU core is powered on, but is in an idle mode with the clock turned OFF.

Wake up time and typical use case

The wakeup time from this low power mode is insignificant because the Fast clock from FRO is still running.

The WFI low power mode is mainly used when there is an hardware activity while the Software runs the Idle task. This allows the code execution to be temporarily suspende, thus reducing a bit the power consumption of the device by switching off the processor clock. When an interrupt fires, the processor clock is instantaneously restored to process the Interrupt Service Routine (ISR).

Usage

In order to prevent the software from programming the device to go to a lower low power mode (such as Deep Sleep, Power Down mode or Deep Power Down mode), the component responsible for the hardware drivers must call PWR_SetLowPowerModeConstraint(PWR_WFI) function. When the Hardware activity is completed, the component shall release the constraint by calling PWR_ReleaseLowPowerModeConstraint(PWR_WFI).

Alternatively, the component can call PWR_LowPowerEnterCritical() and then PWR_LowPowerExitCritical() functions.

For fine tuning of the low power mode allowing more power saving, the component can call directly the SDK Power Manager API with PM_SetConstraints() function using the appropriate low power mode and low power constraint. However, this is reserved for more advanced users who know the device very well. It is not recommended to do so.

The PWR module has no external dependencies, so the low-power entry and exit callback functions must be defined by the user for each peripheral that has specific low power constraints It is consequently convenient to register to the component the low power callbacks structure that is used for entering and exit low power critical sections. In Bluetooth LE, you can take the example in the app_conn.c file as shown below:

```
#if defined(gAppLowpowerEnabled_d) && (gAppLowpowerEnabled_d>0)
static const Seclib_LowpowerCriticalCBs_t app_LowpowerCriticalCBs =
{
  .SeclibEnterLowpowerCriticalFunc = &PWR_LowPowerEnterCritical,
  .SeclibExitLowpowerCriticalFunc  = &PWR_LowPowerExitCritical,
};
#endif

void BluetoothLEHost_Init(..)
{
  ...
      /* Cryptographic hardware initialization */
      SecLib_Init();
#if defined(gAppLowpowerEnabled_d) && (gAppLowpowerEnabled_d>0)
      /* Register PWR functions into SecLib module in order to disable device lowpower
         during Seclib processing. Typically, allow only WFI instruction when
         commands (key generation, encryption) are processed by Seclib  */
      SecLib_SetLowpowerCriticalCb(&app_LowpowerCriticalCBs);
#endif
  ...
}
```

Limitations

No limitation when using the WFI mode.

3.2 Sleep mode

Sleep mode is similar to WFI low power mode but with some additional clock gating. The Sleep mode is device-specific. Therefore, you may refer to the hardware Reference manual of the device for more information.

3.2 Deep Sleep mode

Definition

In Deep Sleep mode, the fast clock is turned off, and the CPU along with the main power domain are placed into a retention state, with the voltage being scaled down to support state retention only. Because no high frequency clock is running, the voltage applied on the power domain can be reduced to reduce leakage on the hardware logic. This reduces the overall power consumption in the Deep Sleep mode. When waking up from Deep sleep mode, the core voltage is

increased back to nominal voltage and the fast clock (FRO) is turned back on, the peripheral in this domain can be reused as normal.

To same more additional power, Some unused RAM banks can be powered off. this prevents from having current leakage and consequently, allow to reduce even more the power consumption in Deep SLeep mode. This is achieved by calling PLATFORM_SetRamBanksRetained() from low power entry function from the board_lp.c file.

Usage

All firmware is able to implement Deep Sleep mode transparently to the application due to the PWR module, low power platform submodule, and the low power board file. This is described in the section Low-power implementation.

When entering this mode, it is recommended to turn the output pins into input mode, or high impedance to reduce leakage on the pads. This is typically done in pin_mux.c file, called from board.c file and executed from the low power callback in board_lp.c file. As an example, the TX line of the UART peripheral can be turned to disabled so it prevents the current from being drawn by the pad in low power mode.

Wake up time and typical use case

The wake up time is very fast, it takes mostly the time for the Fast FRO to start up again (couple of hundreds of microseconds). Therefore, this mode is a very good balance between power consumption in low-power mode and wake up latency. This mode is used extensively in most of the use cases of the application.

Limitations

In Deep Sleep mode, the clock is disabled to the CPU and the main peripheral domain, so peripheral activity (for example, an ongoing DMA transfer) is not possible in Deep Sleep mode.

3.3 Power down mode

Definition

In power-down mode, both the clock, and power are shut off to the CPU and the main peripheral domain. The SRAM is retained but register values are lost. The SDK Power Manager handles the restore of the processor registers and dependencies such as interrupt controller and similar ones transparently from the application.

Usage

The application, with the help of the low power board files, saves and restores the peripherals that were located in the power domain during the entry and exit of the power down mode. This is done from low power board_lp files in the entry/exit low power callbacks. An example is given for the serial manager and debug console in board_lp.c file in the function BOARD_ExitPowerDownCb().

If the device contains a dedicated wake up power domain where some wake up peripherals are located, if this wake up domain is not turned into power down mode but only Deep sleep mode or active mode, this peripheral does not need for a save and restore on low power entry/exit. For instance, on KW45, This is basically achieved when enabling the wakeup source of the peripheral *PWR_EnableWakeUpSource()* from APP_ServiceInitLowpower() function. Alternatively, this can be directly achieved by setting the constraint to the SDK power manager by calling PM_SetConstraints(), (use APP_LPUART0_WAKEUP_CONSTRAINTS for wakeup from UART constraint).

On exit from low power, The low power state of power domain can be retrieved by Platform API PLATFORM_GetLowpowerMode(). This API shall be called from low power exit callback function only.

As for Deep Sleep mode, software shall configure the output pins into input or high impedance during the Low Power mode to avoid leakage on the pads.

Wake up time and typical use case

The wake up time is significantly longer than wake up time from Deep Sleep (from several hundreds of micro-seconds to a couple of milliseconds depending on the platform). On some platform, it can takes longer, for instance, if ROM code is implemented and perform authentication checks for security and hardware logic in power domain needs to be restored (case for KW45). However, After ROM code execution, the SDK power manager resumes the Idle task execution from where it left before entering low-power mode. Hence, the wakeup time from this mode is still significantly lower that the initialization time from a power on reset or any other reset.

Depending on the wakeup time of the platform and the low power time duration, This mode is recommended when no Software activity is expected to happen for the next several seconds. In Bluetooth LE, this mode is preferred in advertising or without Bluetooth LE activity. However, in scanning or connected mode, Regular wakes up happens regularly for instance to retrieve HCI message responses from the Link layer, the Deep Sleep mode is rather recommended.

Limitations

In addition to the Deep Sleep limitation (no Hardware processing on going when going to Power down mode) and the significant increase of the wake time, the Power Down mode requires the ROM code to execute and this last uses a significant amount of memory in the SRAM.

Typically, The first SRAM bank (16 KBytes) is used by the ROM code during execution so the Application firmware can use this section of SRAM for storing bss, rw data, or stacks. Only temporary data could be stored here and this location is overwritten on every Power Down exit sequence.

In order to avoid placing firmware data section (bss, rw, etc.) in the first SRAM bank, the linker script variable *gLowpowerPowerDownEnable_d* should be set to 1. Setting the linker script variable to avoid placing firmware data section in the first SRAM bank, The effect of setting this flag is to prevent the firmware from using the first 16 KB in SRAM.

> *Note* : This setting is ONLY required if the application implements Power Down mode.
> If Application uses other low-power mode, this is not required.

3.4 Deep Power-down mode

Definition

In Deep Power Down mode, the SRAM memory is not retained. This power mode consumes the lowest power and is exited through a reset sequence.

Usage

In addition to the Power Down limitation, the Deep Power Down mode shuts down all the memory in the SRAM. Since it is exited through a reset sequence, the wake up time is also longer.

Wake up time and typical use case

This low-power mode is exited through a reset sequence. Consequently, the wake up time is longer than in any other mode. In Bluetooth LE, using this mode is possible when there is no Bluetooth LE activity. It is preferable to use this mode if there is no Bluetooth LE activity before a certain time interval.

Limitations

All the memory in SRAM is shut down in the Deep Power Down mode. The main limitation in going to this low-power mode is that the context is not saved.

ModuleInfo Overview

The ModuleInfo is a small Connectivity Framework module that provides a mechanism that allows stack components to register information about themselves.

The information comprises :

- Component or module name (for example: Bootloader, IEEE 802.15.4 MAC, and Bluetooth LE Host) and associated version string
- Component or module ID
- Version number
- Build number

The information can be retrieved using shell commands or FSCI commands.

Detailed data types and APIs used in ConnFWK_APIs_documentation.pdf.

NVM: Non-volatile memory module Overview

In a standard Harvard-architecture-based MCU, the flash memory is used to store the program code and program constant data. Modern processors have a built-in flash memory controller that can be used under user program execution to store non-volatile data. The flash memories have individually erasable segments (sectors) and each segment has a limited number of erase cycles. If the same segments are used to store various kinds of data all the time, those segments quickly become unreliable. Therefore, a wear-leveling mechanism is necessary to prolong the service life of the memory. The NVM module in the connectivity framework provides a file system with a wear-leveling mechanism, described in the subsequent sections. The *NvIdle()* function handles the program and erase memory operations. Before resetting the MCU, *NvShutdown()* must be called to ensure that all save operations have been processed.

NVM boundaries and linker script requirement

Most of the MCUs have only a standard flash memory that the non-volatile (NV) storage system uses. The amount of memory that the NV system uses for permanent storage and its boundaries are defined in the linker configuration file though the following linker symbols :

- NV_STORAGE_START_ADDRESS
- NV_STORAGE_END_ADDRESS
- NV_STORAGE_MAX_SECTORS
- NV_STORAGE_SECTOR_SIZE

The reserved memory consists of two virtual pages. The virtual pages are equally sized and each page is using one or more physical flash sectors. Therefore, the smallest configuration is using two physical sectors, one sector per virtual page.

NVM Table

The Flash Management and Non-Volatile Storage Module holds a pointer to a RAM table. The upper layers of this table register information about data that the storage system should save and restore. An example of NVM table entry list is given below.

pData	ElemCount	ElemSize	EntryId	EntryType
0x1FFF9000	3	8	0xF1F4	MirroredInRam
0x1FFF7640	5	4	0xA2A6	NotMirroredInRam
0x1FFF1502	6	1	0x4212	NotMirroredInRam AutoRestore
0x1FFFF200	2	6	0x118F	MirroredInRam

NVM Table entry

As show above, A NVM table entry contains a generic pointer to a contiguous RAM data structure, the number of elements the structure contains, the size of a single element, a table entry ID, and an entry type.

A RAM table entry has the following structure:

- pData (4 bytes) is a pointer to the RAM memory location where the dataset elements are stored.
- elemCnt (2 bytes) represents how many elements the dataset has.
- elemSz (2 bytes) is the size of a single element.
- entryID is a 16-bit unique ID of the dataset.
- dataEntryType is a 16-bit value representing the type of entry (mirrored/unmirrored/unmirrored auto restore).

For mirrored datasets, pData must point directly to the RAM data. For unmirrored datasets, it must be a double pointer to a vector of pointers. Each pointer in this table points to a RAM/FLASH area. Mirrored datasets require the data to be permanently kept in RAM, while unmirrored datasets have dataset entries either in flash or in RAM. If the unmirrored entries must be restored at the initialization, NotMirroredInRamAutoRestore should be used. The entryID gUnmirroredFeatureSet_d should be set to 1 for enabling unmirrored entries in the application. The last entry in the RAM table must have the entryID set to gNvEndOfTableId_c.

pData	0x1FFF8000
elemCnt	4
elemSz	10
entryID	1
dataEntryType	gNVM_NotM gNVM_NotM

4 bytes	4 bytes	4 bytes
0x1FFF0000	0x1FFF1280	0x1FFF1200

10 bytes	10 bytes	10 bytes
DATA1	DATA2	DATA3

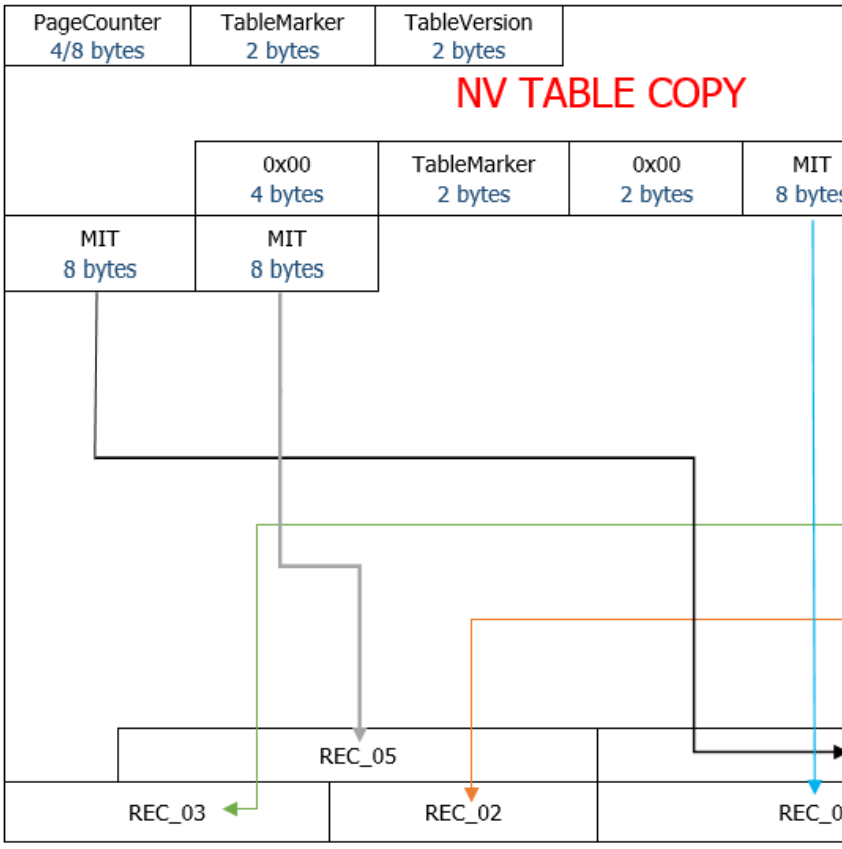
The figure below provides an example of table entry :

When the data pointed to by the table entry pointer (pData) has changed (entirely or just a single element), the upper layers call the appropriate API function that requests the storage system to save the modified data. All the save operations (except for the synchronous save and atomic save) and the page erase and page copy operations are performed on system idle task. The application must create a task that calls NvIdle in an infinite loop. It should be created with OSA_PRIORITY_IDLE. However, the application may choose another priority. The save operations are done in one virtual page, which is the active page. After a save operation is performed on an unmirrored dataset, pData points to a flash location and the RAM pointer is freed. As a result, the effective data should always be allocated using the memory management module.

Active page

The active page contains information about the records and the records. The storage system can save individual elements of a table entry or the entire table entry. Unmirrored datasets can only have individual saves. On mirrored datasets, the save/restore functions must receive the pointer to RAM data. For example, if the application must save the third element in the above vector, it should send 0x1FFF8000 + 2 * elemSz. For unmirrored datasets, the application must send the pointer that points to the area where the data is located. For example, if the application must save the third element in the above vector, it should send 0x1FFF8000 + 2 * sizeof(void*).

The page validity is guaranteed by the page counter. The page counter is a 32-bit value and



is written at the beginning and at the end of the active page. The values need to be equal to consider the page a valid one. The value of the page counter is incremented after each page copy operation. A page erase operation is performed when the system is formatted. It is also performed when the page is full and a new record cannot be written into that page. Before being erased, the full page is first copied (only the most recent saves) and erased afterward.

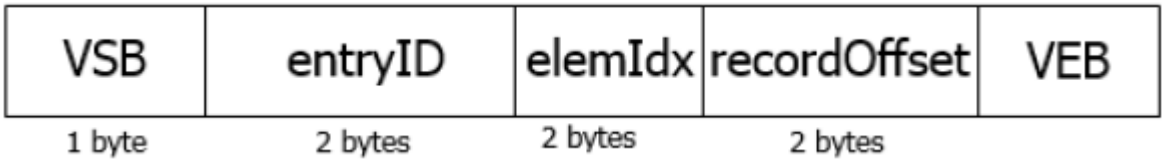
The validity of the Meta Information Tag (MIT), and, therefore, of a record, is guaranteed by the MIT start and stop validation bytes. These two bytes must be equal to consider the record referred by the MIT valid. Furthermore, the value of these bytes indicates the type of the record, whether it is a single element or an entire table entry. The nonvolatile storage system allows dynamic changes of the table within the RAM memory, as follows:

- Remove table entry
- Register table entry

A new table entry can be successfully registered if there is at least one entry previously removed or if the NV table contains uninitialized table entries, declared explicitly to register new table entries at run time. A new table entry can also replace an existing one if the register table entry is called with an overwrite set to true. This functionality is disabled by default and must be enabled by the application by setting gNvUseExtendedFeatureSet_d to 1.

The layout of an active page is shown below:

As shown above, the table stored in the RAM memory is copied into the flash active page, just after the table version. The “table start” and “table end” are marked by the table markers. The data pointers from RAM are not copied. A flash copy of a RAM table entry has the following structure:



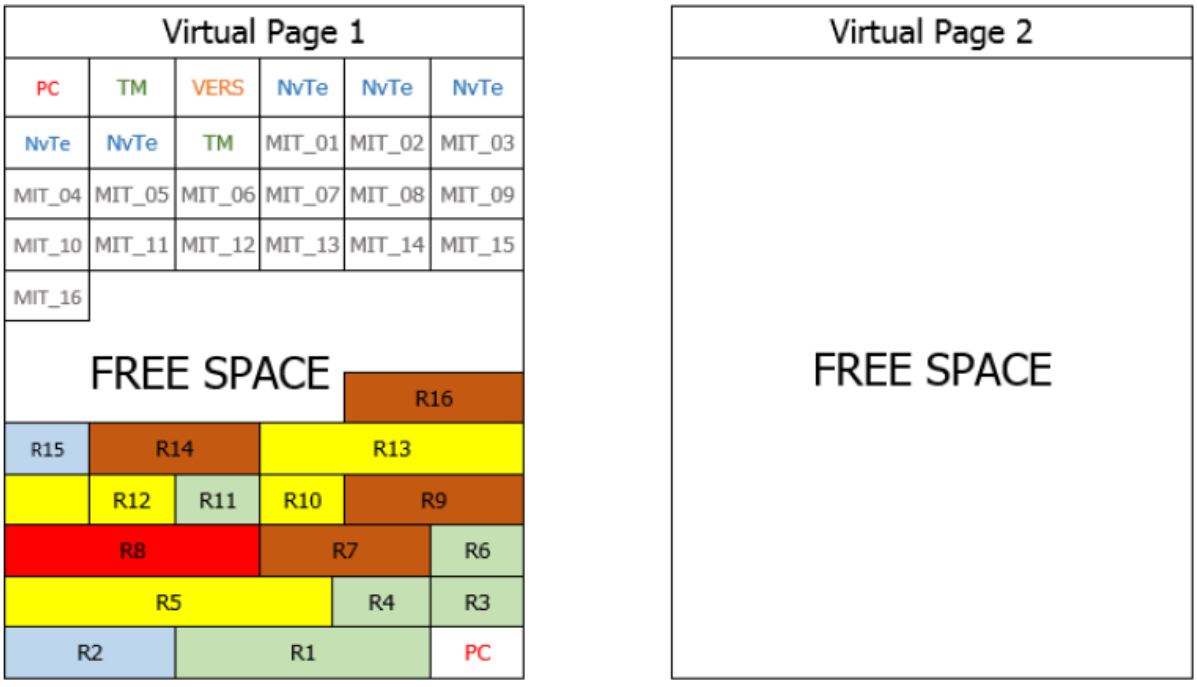
Where:

- entryID is the ID of the table entry

- entryType represents the type of the entry (mirrored/unmirrored/unmirrored auto restore)
- elemCnt is the elements count of that entry
- elemSz is the size of a single element

This copy of the RAM table in flash is used to determine whether the RAM table has changed. The table marker has a value of 0x4254 (“TB” if read as ASCII codes) and marks the beginning and end of the NV table copy.

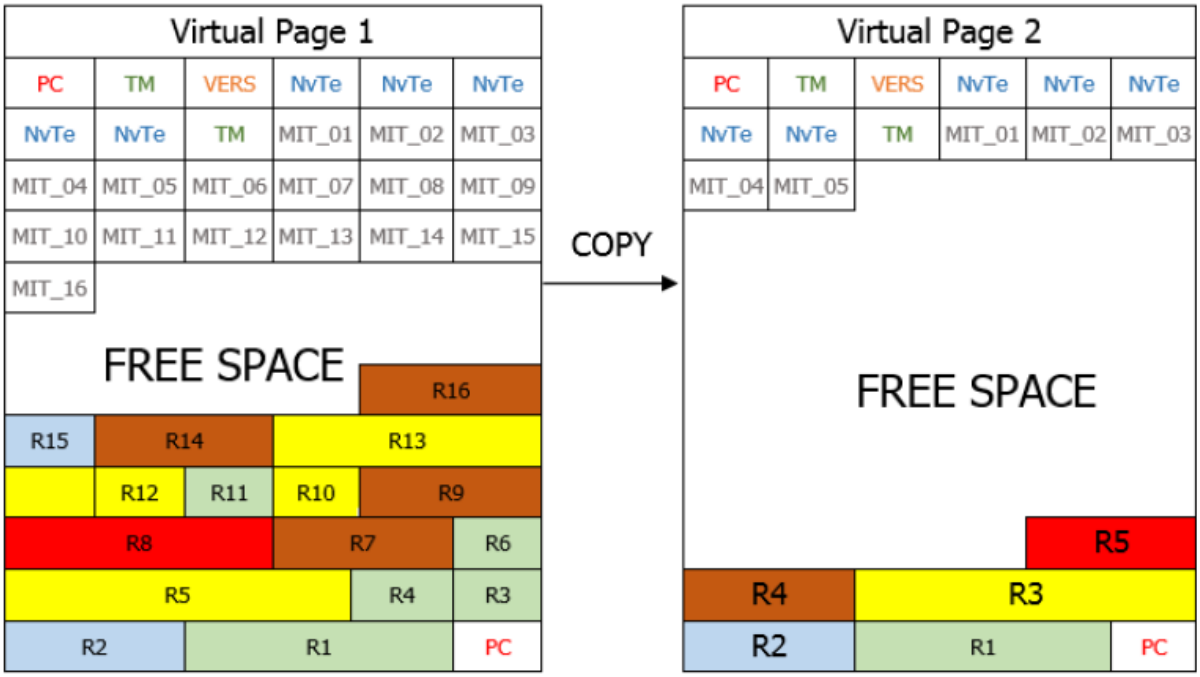
After the end of the RAM table copy, the Meta Information Tags (MITs) follow. Each MIT is used to store information related to one record. An MIT has the following structure:



Where:

- VSB is the validation start byte.
- entryID is the ID of the NV table entry.
- elemIdx is the element index.
- recordOffset is the offset of the record related to the start address of the virtual page.
- VEB is the validation end byte.

A valid MIT has a VSB equal to a VEB. If the MIT refers to a single-element record type, VSB=VEB=0xAA. If the MIT refers to a full table entry record type (all elements from a table entry), VSB=VEB=0x55. Because the records are written to the flash page, the available page space decreases. As a result, the page becomes full and a new record does not have enough free space to be copied into that page.



In the example given below, the virtual page 1 is considered to be full if a new save request is pending and the page free space is not sufficient to copy the new record and the additional MIT. In this case, the latest saved datasets (table entries) are copied to virtual page 2.

In this example, there are five datasets (one color for each dataset) with both ‘full’ and ‘single’ record types.

- R1 is a 'full' record type (contains all the NV table entry elements), whereas R3, R4, R6 and R11 are 'single' record types.
- R2 – full record type; R15 – single record type
- R5, R13 – full record type; R10, R12 – single record type
- R8 – full record type
- R7, R9, R14, R16 – full record type

As shown above, the R3, R4, R6, and R11 are 'single' record types, while R1 is a 'full' record type of the same dataset. When copied to virtual page 2, a defragmentation process takes place. As a result, the record copied to virtual page 2 has as much elements as R1, but individual elements are taken from R3, R4, R6, and R11. After the copy process completes, the virtual page 2 has five 'full' record types, one for each dataset. |This is illustrated below:

Finally, the virtual page 2 is validated by writing the PC value and a request to erase virtual page 1 is performed. The page is erased on an idle task, sector by sector where only one sector is erased at a time when idle task is executed.

If there is any difference between the RAM and flash tables, the application must call RecoverNvEntry for each entry that is different from its RAM copy to recover the entry data (ID, Type, ElemSz, ElemCnt) from flash before calling NvInit. The application must allocate the pData and change the RAM entry. It can choose to ignore the flash entry if the entry is not desired. If any entry from RAM differs from its flash equivalent at initialization, a page copy is triggered that ignores the entries that are different. In other words, data stored in those entries is lost.

The application can check if the RAM table was updated. In other words, if the MCU program was changed and the RAM table was updated, using the function GetFlashTableVersion and compare the result with the constant gNvFlashTableVersion_c. If the versions are different, NvInit detects the update and automatically upgrades the flash table. The upgrade process triggers a page copy that moves the flash data from the active page to the other one. It keeps the entries that were not modified intact and it moves the entries that had their elements count changed as follows:

- If the RAM element count is smaller than the flash element count, the upgrade only copies as many elements as are in RAM.
- If the RAM element count is larger than the flash element count, the upgrade copies all data from flash and fills the remaining space with data from RAM. If the entry size is changed, the entry is not copied. Any entryIds that are present in flash and not present in RAM are

also not copied. This functionality is not supported if gNvUseExtendedFeatureSet_d is not set to 1.

ECC Fault detection

The KW45/K32W1 internal flash is organized in 16 byte phrases and 8kB sectors (minimal erase unit). Its flash controller is synthesized so that it generates ECC information and an ECC generator / checker. During the programming of internal flash, errors may accidentally happen and cause ECC errors as a flash phrase is being written. These may happen due to multiple reasons:

- programmatic errors such as overwriting an already programmed phrase (transitioning bits from 0b to 1b). These are evitable by performing a blank check verification over phrase to be programmed, at the expense of processing power.
- occurrence of power drop or glitches during a programming operation.
- excessive wear of flash sector. The flash controller is capable of correcting one single ECC error but raises a bud fault whenever reading a phrase containing more than one ECC fault. Once an ECC error has 'infected' a flash phrase, the fault will remain and raise again at each read operation over the same phrase including blank check and prefetch. It can only be rid of by erasing the whole flash sector that contained the faulty phrase. In order to recover from situations where an ECC fault has occurred a gNvSalvageFromEccFault_d option has been added, which forces gNvVerifyReadBackAfterProgram_d to be defined to TRUE. If defined, the gNvVerifyReadBackAfterProgram_d option of the NVM module, causes the program to read back the programmed area after every flash programming operation. The verification is performed in safe mode if gNvSalvageFromEccFault_d is also defined. This is so as to detect ECC faults as early as possible as they appear, indeed when verifying a programming operation, one cannot be certain of the absence of ECC fault and avoid the bus fault. The safe API is thence used to perform the read back operation is performed using this safe API, so that we can tread in the flash and detect potential errors. The defects are detected on the fly whereas in the absence of safe read back, the error would cause a fault, potentially much later. During normal operation, assuming that no chip reset was provoked, this will consist in a single ECC fault either in the last record data or its meta information. Detecting such a fault calls for an immediate page copy to the other virtual page, so that the currently active page gets erased and the error gets cleared. Should the ECC fault occurs in the middle of a page copy operation, the switch of active page is postponed so that the fault page can be erased again and the copy can be restarted.

If the system underwent a power drop during a flash programming operation, sufficient to provoke a reset, at the ensuing reboot, ECC fault(s) may be present in the NVM area at the location that was being written. The detection is performed by an NVM sweeping mechanism, using the safe read API. That marks the faulty virtual page so that all subsequent reads within this virtual page are done with the safe API. If this case arises, a copy of the valid contents of the faulty page is attempted to the other virtual page. At NVM initialization, faults should be detected, either at the top of the meta data or at the bottom of the record area within the previous active page. This should guarantee that only the latest record write operation may be impaired. When the page copy has taken place, the faulty page is erased and the execution may resume. During NvCopyPage, when 'garbage collecting' occurs or whenever the current virtual active page needs to be transferred to the other virtual page, ECC errors are intercepted so that the operation can be attempted again in case of error. In case of NVM contents clobbering by programming errors, the salvage operation does its best to rescue as many records as possible but data will inevitably be lost.

An additional option -namely *gInterceptEccBusFaults_d* - was introduced in order to catch and correct ECC faults at Bus Fault handler level. Indeed, should an ECC bus fault fire, in spite of the precautions taken with NVM's gNvSalvageFromEccFault_d, we verify if the fault belongs to the NV storage. If so, a drastic policy can be adopted consisting in an erasure of the faulty sector. The corresponding Bus Fault handling is not part of the NVM, but dwells in the framework platform specific sources. Alternative handling could be implemented by the customer.

Save policy:

Execution of program and erase operations on a flash an MCU core fetches code from cause perturbations of the core activity or requires to place critical code in RAM so that real-time ISR can still be served. The penalty of a sector erase is much higher than a simple program operation. The NVM is designed so as to limit the erase operations at 'garbage collecting' time, so that flash wear is limited and no time is wasted. Several write policies are implemented to cope with the application constraints, one synchronous mode API and several posted write APIs. Among the posted write policies, the gNvmSaveOnIdleTimerPolicy_d compilation option selects a mode where flash write operations occur at time interval within the Idle task. Another option exists to 'randomize' the time interval with some jitter.

1) NvSyncSave performs a write synchronously with the disadvantage of stalling processor activity until comp
2) NvSaveOnCount posts a pending write operation and postpones the actual flash operation until number of record updates has reached a maximum. The actual write happens during Idle Task execution.see NvSetCountsBetweenSaves related API.
3) NvSaveOnInterval: posts a pending write operation and postpones the actual flash operation until the predefined number of ticks has elapsed. Optional mode - Active if (gNvmSaveOnIdleTimerPolicy_d & gNvmUseSaveOnTimerOn_c). see NvSetMinimumTicksBetweenSaves related API. Note that gNvmUseSaveIntervalJitter_c policy is a sub-option of gNvmSaveOnIdleTimerPolicy_d used to randomize slightly the time at which the write operation will happen.

Constant macro definition

- *gNvStorageIncluded_d* : If set to TRUE, it enables the whole functionality of the nonvolatile storage system. By default, it is set to FALSE (no code or data is generated for this module).
- *gNvUseFlexNVM_d* : If set to TRUE, it enables the FlexNVM functionality of the nonvolatile storage system. By default, it is set to FALSE. If FlexNVM is used, the standard nonvolatile storage system is disabled.
- *gNvFragmentation_Enabled_d* : Macro used to enable/disable the fragmented saves/restores (a particular element from a table entry can be saved or restored). It is set to FALSE by default.
- *gNvUseExtendedFeatureSet_d* : Macro used to enable/disable the extended feature set of the module:
  - Remove existing NV table entries
  - Register new NV table entries
  - Table upgrade

  It is set to FALSE by default.
- *gUnmirroredFeatureSet_d* : Macro used to enable unmirrored datasets. It is set to 0 by default.
- *gNvTableEntriesCountMax_c* : This constant defines the maximum count of the table entries (datasets) that the application is going to use. It is set to 32 by default.
- *gNvRecordsCopiedBufferSize_c* : This constant defines the size of the buffer used by the page copy function, when the copy operation performs defragmentation. The chosen value must be bigger than the maximum number of elements stored in any of the table entries. It is set by default to 64.
- *gNvCacheBufferSize_c* : This constant defines the size of the cache buffer used by the page copy function, when the copy operation does not perform defragmentation. The chosen value must be a multiple of 8. It is set by default to 64.

- *gNvMinimumTicksBetweenSaves_c* : This constant defines the minimum timer ticks between dataset saves (in seconds). It is set to 4 by default.
- *gNvCountsBetweenSaves_c* : This constant defines the number of calls to 'NvSaveOnCount' between dataset saves. It is set to 256 by default.
- *gNvInvalidDataEntry_c* : Macro used to mark a table entry as invalid in the NV table. The default value is 0xFFFFU.
- *gNvFormatRetryCount_c* : Macro used to define the maximum retries count value for the format operation. It is set to 3 by default.
- *gNvPendingSavesQueueSize_c* : Macro used to define the size of the pending saves queue. It is set to 32 by default.
- *gFifoOverwriteEnabled_c* : Macro used to enable overwriting older entries in the pending saves queue (if it is full). If it is FALSE and the queue is full, the module tries to process the oldest save in the queue to free a position. It is set to FALSE by default.
- *gNvMinimumFreeBytesCountStart_c* : Macro used to define the minimum free space at initialization. If the free space is smaller than this value, a page copy is triggered. It is set by default to 128.
- *gNvEndOfTableId_c* : Macro used to define the ID of the end-of-table entry. It is set to 0xFFFEU by default. No valid entry should use this ID.
- *gNvTableMarker_c* : Macro used to define the table marker value. The table marker is used to indicate the start and the end of the flash copy of the NV table. It is set to 0x4254U by default.
- *gNvFlashTableVersion_c* : Macro used to define the flash table version. It is used to determine if the NVM table was updated. It is set to 1 by default. The application should modify this every time the NVM table is updated and the data from NVM is still required.
- *gNvTableKeptInRam_d* : Set gNvTableKeptInRam_d to FALSE, if the NVM table is stored in FLASH memory (default). If the NVM table is stored in RAM memory, set the macro to TRUE.
- *gNvVerifyReadBackAfterProgram_d* : set by default force verification of NVM programming operations. Is forced implicitly when gNvSalvageFromEccFault_d is defined.
- *gNvSalvageFromEccFault_d* : use safe flash API to read from flash, and provide corrective action when ECC fault is met.

OtaSupport: Over-the-Air Programming Support Overview

This module includes APIs for the over-the-air image upgrade process. A Server device receives an image over the serial interface from a PC or other device thorough FSCI commands. If the Server has an image storage, the image is saved locally. If not, the image is requested chunk by chunk: With image storage

- OTA_RegisterToFsci()
- OTA_InitExternalMemory()
- OTA_WriteExternalMemory()
- ...
- OTA_WriteExternalMemory()

Without image storage:

- OTA_RegisterToFsci()
- OTA_QueryImageReq()
- OTA_ImageChunkReq()

- ...
- OTA_ImageChunkReq()

A Client device processes the received image by computing the CRC and filter unused data and stores the received image into a non-volatile storage. After the entire image has been transferred and verified, the Client device informs the Bootloader application that a new image is available, and that the MCU must be reset to start the upgrade process. See the following command sequence:

- OTA_StartImage()
- OTA_PushImageChunk() and OTA_CrcCompute ()
- ...
- OTA_PushImageChunk() and OTA_CrcCompute ()
- OTA_CommitImage()
- OTA_SetNewImageFlag()
- ResetMCU()

SecLib_RNG: Security library and random number generator SecLib Implementation Flavors

Overview

The NXP Connectivity Framework provides multiple SecLib implementations (flavors) to support different hardware capabilities, security requirements, and performance needs. Each flavor offers the same high-level cryptographic APIs but with different underlying implementations optimized for specific use cases.

Available SecLib Flavors

1. Software SecLib (SecLib.c)(RNG.c)

Description: Pure software implementation providing cryptographic operations if no hardware is available.

Platforms: all platforms

Characteristics:

- Platform-independent software implementation
- No hardware acceleration requirements
- Consistent behavior across all platforms
- Higher CPU usage and power consumption
- Suitable for platforms without crypto hardware

Files: SecLib.c, RNG.c

2. EdgeLock SecLib (SecLib_sss.c)(RNG.c)

Description: Hardware-accelerated implementation using NXP's EdgeLock secure subsystem s200.

Platforms: devices with S200: KW45, KW47, MCXW71, MCXW72

Characteristics:

- Hardware-backed security operations
- Secure key storage in hardware
- Hardware random number generation
- Lower CPU usage, better performance
- Enhanced security through hardware isolation
- Platform-specific (requires Secure Subsystem API)

Files: SecLib_sss.c, RNG.c

3. PSA Crypto SecLib (SecLib_psa.c)(RNG_psa.c)

Description: Implementation based on ARM's Platform Security Architecture (PSA) Crypto API standard.

Platforms: MCXW23, (MCXW71 and MCXW72 for evaluation)

Characteristics:

- Industry-standard API
- Hardware acceleration when available
- Secure key management
- Future-proof and portable
- Compliance-ready

Files: SecLib_psa.c, SecLib_psa_config.h RNG_psa.c

Flavor Selection

SecLib flavor is described in 'Kconfig' and selected inside prj.conf or defconfig. Define one of this line to override the default configuration for your board:

```
CONFIG_MCUX_COMPONENT_middleware.wireless.framework.seclib_rng_port.sw=y
CONFIG_MCUX_COMPONENT_middleware.wireless.framework.seclib_rng_port.secure_subsystem=y
CONFIG_MCUX_COMPONENT_middleware.wireless.framework.seclib_rng_port.psa=y
```

The necessary configuration files are automatically added inside of CmakeLists.txt

Random number generator

Overview

The RNG module is part of the framework used for random number generation. It uses hardware RNG peripherals as entropy sources (TRNG, Secure Subsystem, ...) to provide a true random number generator interface. A Pseudo-Random number generator (PRNG) implementation is available. The PRNG may depend of SecLib services (thus requiring a common mutex) to perform HMAC-SHA256, SHA256, AES-CTR, or alternateively a Lehmer Linear Congruential generator. A prerequisite for the PRNG to function with desired randomness is to be seeded using a proper source of entropy. If no hardware acceleration is present, the RNG may fallback to lesser quality ad-hoc source e.g if present SIM_UID registers, the UIDL is used as the initial seed for the random number generator.

Initialization

The RNG module requires an initialization via a call to RNG_Init. The RNG initialization involves a call to RNG_SetSeed.

In the case of a dual core system consisting of a Host core and an NBU core, the Secure Subsystem is owned by the Host core. The Host core then has a direct access to its TRNG embedded in its secure subssystem. On the NBU code side, a request is emitted via RPMSG to the Host to provide a seed. On receipt of this request, the Host sets a 'reseed needed' flag (from the ISR context) If the core running the RNG service owns the TRNG entropy hardware (if any), it can get the seed directly form this hardware synchronously. In the case of an NBU that does not control the devices entropy source, that is owned by the Host, it request a seed from the Host processor via RPMSG exchange. On receipt of this request the Host sets a flag notifying of this request from the RPMSG ISR context.

RNG_ReInit API is to be used at wake up time in the context of LowPower. RNG_DeInit is used for unit tests and coverage purposes but has no useful role in a real application.

Asynchronous Seed Handling Enhancement

The RNG module has been enhanced to use the framework's work queue system instead of polling from the IDLE thread.

Key Changes:

- **Work Queue Integration**: RNG_NotifyReseedNeeded() now submits seed operations to the work queue on Host cores
- **Non-blocking**: Replaces previous IDLE thread polling with asynchronous work queue scheduling
- **ISR-Safe**: Seed requests from ISR context are safely deferred to work queue execution

Benefits:

- Improved system responsiveness by removing IDLE thread dependency
- Better resource management through work queue scheduling

Seed handling

RNG_SetSeed: RNG_SetExternalSeed may be used to inject application entropy to RNG context seed using a supplied array of bytes. RNG_IsReseedNeeded used from task in Host core to check whether seed must be sent to NBU core.

RNG_GetTrueRandomNumber is the API used to generate a Random 32 bit number from a HW source of entropy. It is essential if only to seed the pseudo random number generator.

RNG_GetPseudoRandomData is used to generate arrays of random bytes.

RNG_NotifyReseedNeeded Enhanced to use work queue submission on Host cores instead of requiring IDLE thread polling. Sets reseed flag and schedules asynchronous seed generation.

Security Library

Overview

The framework provides support for cryptography in the security module. It supports both software and hardware encryption. Depending on the device, the hardware encryption uses either the S200, MMCAU, LTC, or CAU3 module instruction set or dedicated AES and SHA hardware blocks.

Software implementation is provided in a library format.

Support for security algorithms

	SW Seclib : SecLib.c	EdgeLock SecLib_sss.c	Seclib_ps	nccl (part of SecLib.c)	Usage example
AES_128	SecLib_aes.c	x	x		
AES_128_ECB		x	x		
AES_128_CBC	x	x			
AES_128_CTR encryption	x	x			
AES_128_OFB Encryption	x				
AES_128_CMAC	x	x	x		BLE connection, ieee 15.4
AES_128_EAX	x				
AES_128_CCM	x	x	x		BLE, ieee 15.4
SHA1	SecLib_sha.c	x			
SHA256	x	x	x		
HMAC_SHA256	x	x			PRNG, Digest for Matter
ECDH_P256 shared secret generation	x (by 15 incremental steps) -> SecLib_ecdh.c	x with MACRO SecLibECDHUseSSS	x	x	BLE pairing,
EC_P256 key pair generation	x	x	x	x	
EC_P256 public key generation from private key				x	Matter (ECDSA)
ECDSA_P256 hash and msg signature generation / verification		only if owner of the key pair		x	Matter
SPAKE2+ P256 arithmetics				x	Matter

SecLib_psa

The framework provides PSA (Platform Security Architecture) Crypto API support through the SecLib_psa.c implementation. This provides a standardized cryptographic interface that can leverage hardware acceleration when available.

Configuration

PSA support is configured through the SecLib_psa_config.h file, which defines:

- Hardware acceleration capabilities via MBEDTLS_PSA_ACCEL_* macros
- Memory management integration with the framework's memory manager
- External RNG integration

Advantages of PSA Crypto API

Standardization and Portability

- **Vendor Independence**: Applications using PSA APIs can be easily ported between different hardware platforms without changing cryptographic code
- **Industry Standard**: PSA Crypto API is an ARM-defined industry standard (PSA Certified), ensuring consistent behavior across different platforms and vendors
- **Future-Proof**: As an evolving standard, PSA provides long-term compatibility and support for emerging cryptographic requirements

Security Benefits

- **Secure Key Management**: PSA provides built-in secure key storage and lifecycle management, reducing the risk of key exposure
- **Hardware Security Integration**: Seamless integration with hardware security modules (HSMs) and secure elements when available
- **Isolation**: Keys and cryptographic operations can be isolated from application code, reducing attack surface
- **Tamper Resistance**: Hardware-backed implementations provide protection against physical attacks

BLE advanced secure mode

New elements in existing structures:

computeDhKeyParam_t::keepInternalBlob - boolean telling if the shared blob is kept in this structure(in .outpoint) after ECDH_P256_ComputeDhKey() or ECDH_P256_ComputeDhKeySeg() call.

New arguments in existing functions:

ECDH_P256_ComputeDhKey keepBlobDhKey - boolean telling ECDH_P256_ComputeDhKey() or ECDH_P256_ComputeDhKeySeg() to keep the shared object after computation for later use (it is required by the SecLib_GenerateBluetoothF5KeysSecure).

New macros:

gSecLibSssUseEncryptedKeys_d - Enable or disable S200 blobs SecLib support. 0 - the Bluetooth Keys are available in plaintext, 1 - the Bluetooth Keys are not available in plaintext, but in secured blobs. Default is disabled.

New functions:

LE Secure connections pairing:

void ECDH_P256_FreeDhKeyDataSecure

This is a function used to free the shared object stored in computeDhKeyParam_t. When user calls ECDH_P256_ComputeDhKeySeg() with keepBlobDhKey set to 1, it should also call **ECDH_P256_FreeDhKeyDataSecure** .

SecLib_GenerateBluetoothF5Keys

This function is extracted from the Bluetooth LE Host Stack implementation. This corresponds to the legacy implementation without key blobs.

SecLib_GenerateBluetoothF5KeysSecure

Similar to **SecLib_GenerateBluetoothF5Keys** this function is modified to work with key blobs, the reason is to not use SSS inside the Bluetooth LE Host Stack.

SecLib_DeriveBluetoothSKD

This is a helper function used by the Bluetooth LE Host Stack in the pairing procedure, when receiving the vendor HCI command specifying that the ESK needs to be provided to LL.

ELKE_BLE_SM_F5_DeriveKeys

This is a private function, helper for **SecLib_GenerateBluetoothF5KeysSecure**. It was provided by the STEC team.

Privacy:

SecLib_ObfuscateKeySecure

This is a function used by the Bluetooth LE Host Stack to obfuscate the IRK before setting it to Bluetooth LE Controller or before saving it to NVM

SecLib_DeobfuscateKeySecure

This is a function used by the Bluetooth LE Host Stack to extract the plaintext IRK key from the saved NVM blob.

SecLib_VerifyBluetoothAh

This function is extracted from the legacy Bluetooth LE Host Stack implementation using plaintext keys.

SecLib_VerifyBluetoothAhSecure

Similar to **SecLib_VerifyBluetoothAh** with modification to work with S200 key blob.

SecLib_GenerateSymmetricKey

This is a function used by the application to generate the local IRK and local CSRK.

SecLib_GenerateBluetoothEIRKBlobSecure

This is a function used by the application to generate the EIRK needed by Bluetooth LE Controller from the IRK blob.

A2B feature

ECDH_P256_ComputeA2BKey

This function is used to compute the EdgeLock to EdgeLock key. pInPeerPublicKey points to the peer public key, pOutE2EKey is the pointer to where the E2E key object will be stored, this will be freed by the application when it is no longer required by calling ECDH_P256_FreeE2EKeyData().

ECDH_P256_FreeE2EKeyData

This function is used to free the key object given as a parameter. It is used by the application to free the E2E key when is no longer needed.

SecLib_ExportA2BBlobSecure

This function is used to import an ELKE blob or plain text symmetric key in s200 and export an E2E key blob. The input type is identified by the keyType parameter.

SecLib_ImportA2BBlobSecure

This function is used to import an E2E key blob in s200 and export an ELKE blob or plain text symmetric key. The output type is identified by the keyType parameter.

LE Secure connections Pairing flow and SecLib usage:

1. Each device needs to generate locally the public+private keypair. This is done using **ECDH_P256_GenerateKeys**.
2. Devices exchange their public keys.
3. Upon receiving the peer device's public key, local device is computing DH key using **ECDH_P256_ComputeDhKey**.
4. Each device sends DHKeyCheck packet
5. Upon receiving DhKeyCheck each device computes LTK blob using **SecLib_GenerateBluetoothF5Keys**
6. After computing the each device sends HCI_LeStartEnc (on initiator), HCI_Le_Provide_Long_Term_Key (on responder)
7. Bluetooth LE Controller sends back SKD report custom event
8. Bluetooth LE Host Stack computes ESKD based on LTK blob using **SecLib_DeriveBluetoothSKD** and sends it to Bluetooth LE Controller
9. Bluetooth LE Controller encrypts the link

IRK flow and SecLib usage:

1. At startup, when gInitializationComplete_c event is received:

- the local IRK is generated using **SecLib_GenerateSymmetricKey**
- the local EIRK is generated using **SecLib_GenerateBluetoothEIRKBlobSecure**
- local CSRK is generated using **SecLib_GenerateSymmetricKey**

2. During legacy pairing when receiving bonding keys, IRK is obfuscated using **SecLib_ObfuscateKeySecure** and stored
3. When app wants to set the OOB keys using Gap_SaveKeys the IRK is obfuscated using **SecLib_ObfuscateKeySecure**
4. When application calls API Gap_VerifyPrivateResolvableAddress IRK is obfuscated using **SecLib_ObfuscateKeySecure** and verified using **SecLib_VerifyBluetoothAhSecure**
5. When a new connection is received in Host with RPA address not resolved by the Bluetooth LE Controller, the Host tries to resolve it by obfuscating it using **SecLib_ObfuscateKeySecure** and verifying it using **SecLib_VerifyBluetoothAhSecure**
6. When adding a peer in Bluetooth LE Controller resolving list, the peer's IRK is obfuscated using **SecLib_ObfuscateKeySecure** before setting it using **HCI_Le_Add_Device_To_Resolving_List**.
7. When an IRK plaintext is requested by the application using Gap_LoadKeys it is obtained using **SecLib_DeobfuscateKeySecure**
8. When legacy pairing completes and LTK needs to be send in the pairing complete event (gConnEvtPairingComplete_c) the **SecLib_DeobfuscateKey** is used to extract the plaintext.

A2B flow and SecLib usage:

1. At startup, when gInitializationComplete_c event is received, the application will call **ECDH_P256_GenerateKeys** to generate the public/private key pair required for the E2E key derivation and send the public key to the peer device.
2. When the public key is received from the peer device, the application will call **ECDH_P256_ComputeA2BKeySecure** to generate the EdgeLock to EdgeLock key.
3. The application will obtain an E2E IRK blob by calling **SecLib_ExportA2BBlobSecure** with key type gSecElkeBlob_c. The obtained blob is sent to the peer anchor. The peer anchor will call **SecLib_ImportA2BBlob** with keyType gSecElkeBlob_c and save the resulting ELKE blob in NVM, for Digital Key both anchors must have the same IRK.
4. After pairing, in order to send the LTK and IRK contained in the bonding data securely, the application will call **SecLib_ExportA2BBlobSecure** with keyType gSecLtkElkeBlob_c for the LTK, and **SecLib_ExportA2BBlobSecure** with keyType gSecPlainText_c for the IRK. The E2E blobs obtained are sent along with the rest of the bonding data to the peer anchor device.
5. After the bonding data is trasfered the E2E key is no longer needed and **ECDH_P256_FreeE2EKeyData** is called with the key object obtained at step 2 when **ECDH_P256_ComputeA2BKeySecure** was called.

Sensors Overview

The Sensors module provides an API to communicate with the ADC. Two values can be obtained by this module :

- Temperature value
- Battery level

The temperature is given in tenths of degrees Celsius and the battery in percentage.

This module is multi-caller, the ADC is protected by a mutex on the resource and by prevententing lowpower (only WFI) during its processing. Platform specific code can be find in fwk_platform_sensors.c/h.

Features

Manual Measurement

Calling “SENSORS_GetTemperature()” or “SENSORS_GetBatteryLevel()” function will give the last measured value that was copied to RAM. If you want to refresh this value you must first call the trigger function (SENSORS_TriggerTemperatureMeasurement() / SENSORS_TriggerBatteryMeasurement()) that configures the ADC to perform temperature or battery measurement, then a call to the refresh function (SENSORS_RefreshTemperatureValue() / SENSORS_RefreshBatteryLevel()) will read the returned value from the ADC and save it in RAM. You can run code between these two functions because the ADC won’t give you the value until it’s fully ready.

> **Important**: When a measurement is ongoing, new measurement requests will be **dropped**. Measurement triggers are only accepted when the measurement state is **IDLE**. This applies to both temperature and battery measurements to prevent ADC resource conflicts.

Periodic Temperature Measurement

The Sensors module supports automatic periodic temperature measurements that can be requested from two sources:

1. HOST Requests

Applications can request periodic temperature measurements using:

```
SENSORS_TriggerPeriodicTemperatureMeasurement(uint32_t temperature_meas_interval_ms);
```

2. NBU Requests (wireless_mcu platforms only)

The NBU (Narrow Band Unit) can request periodic temperature measurements. For more details about NBU temperature requests check NBU Integration Features section bellow.

Periodic Measurement Behavior

Immediate Trigger: Every periodic request (HOST or NBU) triggers an **immediate measurement** before starting the interval timer.

Interval Management:

- **Minimum Interval Selection**: When both HOST and NBU request periodic measurements, the system uses the **shorter interval**
- **Dynamic Updates**: Changing the interval from either source immediately triggers a new measurement and restarts the timer with the new effective interval
- **Independent Control**: HOST and NBU can independently start/stop their periodic requests

One-shot Mode: Setting interval to 0 triggers a single measurement and stops periodic operation for that source.

Usage Examples

```
// HOST requests periodic measurement every 100ms
SENSORS_TriggerPeriodicTemperatureMeasurement(100);

// HOST requests one-shot measurement and stops periodic operation
SENSORS_TriggerPeriodicTemperatureMeasurement(0);
```

Concurrent Requests Behavior

HOST Interval	NBU Interval	Effective Interval	Notes
200ms	100ms	100ms	NBU interval is shorter
100ms	300ms	100ms	HOST interval is shorter
0 (stopped)	150ms	150ms	Only NBU active
200ms	0 (stopped)	200ms	Only HOST active
0 (stopped)	0 (stopped)	No periodic	Both stopped

Measurement State Management

The Sensors module uses a state machine to manage ADC resource access:

States:

- **MEASUREMENT_IDLE**: No measurement in progress, ready to accept new requests
- **TMP_MEASUREMENT_ONGOING**: Temperature measurement in progress
- **BAT_MEASUREMENT_ONGOING**: Battery measurement in progress

Behavior:

- **Request Acceptance**: New measurement requests are only processed when state is MEASUREMENT_IDLE
- **Request Dropping**: If a measurement request is made while another measurement is ongoing, the new request is silently dropped
- **State Transitions**: State changes from IDLE ONGOING when measurement starts, and back to IDLE when measurement completes
- **Recovery Mechanism**: For periodic measurements, if a trigger fails due to ongoing measurement, a 1ms retry timer is started

NBU Integration Features

Platform Support: NBU integration features are only supported on **wireless_mcu** platforms. These features are **not available** on RT, mcxw23, and rw61x platforms.

Periodic Temperature Measurement from NBU

The Sensors module supports automatic periodic temperature measurements triggered by NBU requests. This feature allows the system to automatically measure temperature at regular intervals without manual intervention. This temperature data is used for XTAL32M calibration and Channel Sounding calibration.

How it works:

1. **NBU Request**: The NBU can request periodic temperature measurements by calling the registered callback with a measurement interval
2. **Timer-based Scheduling**: A timer manager is used to schedule periodic measurements based on the requested interval
3. **Workqueue Processing**: Temperature measurement triggers are processed through the system workqueue to avoid blocking operations
4. **Automatic Refresh**: Once a measurement is complete, the next measurement is automatically scheduled

Key Components:

- **Temperature Request Callback**: Sensors_TemperatureReqCb() - Handles NBU requests for periodic measurements
- **Timer Callback**: Sensors_TempMeasTimerCallback() - Triggers measurements on timer expiration
- **Work Handler**: Sensors_PeriodicTempWorkHandler() - Processes temperature measurement requests in workqueue context
- **Ready Callback**: Sensors_TemperatureReadyCb() - Called when temperature measurement is complete

Usage:

- **One-shot measurement**: NBU requests with interval = 0
- **Periodic measurement**: NBU requests with interval > 0 (in milliseconds)
- The periodic measurement continues until a new request changes the interval or stops it

Temperature Filtering and NBU Communication

Modified Moving Average Filter

On wireless_mcu platforms, temperature readings are processed through a Modified Moving Average (MMA) filter to reduce noise and prevent unnecessary NBU notifications. This filter helps to:

- **Limit XTAL32M calibration changes**: Prevents excessive calibration adjustments that could degrade RF performances
- **Optimize power consumption**: Reduces NBU wake-up events by limiting notifications to significant temperature changes
- **Reduce noise**: Smooths out temperature reading fluctuations for more stable system behavior

The XTAL32M calibration process uses a LUT (Look-Up Table) that contains pre-characterized calibration values mapping temperature ranges to optimal XTAL32M frequency adjustments, enabling precise crystal oscillator tuning based on thermal conditions.

The LUT is registered using `PLATFORM_RegisterXtal32MTempCompLut()` and this is currently done in `examples/_common/project_segments/wireless/wireless_mcu/app_common/hardware_init.c` and requires `gBoardUseXtal32MTempComp` to be enabled.

Configuration: Filter size is controlled by `PLATFORM_TEMPERATURE_FILTER_SIZE` (default: 4 samples)

NBU Temperature Threshold

Temperature values are only sent to the NBU when they exceed a configurable threshold:

Threshold is Controlled by `PLATFORM_TEMP_SENT_NBU_THRESHOLD` (default: 10 tenths of degrees Celsius = 1°C)

Temperature Processing Flow:

1. **Raw Measurement**: ADC interrupt captures temperature reading
2. **Sensors Module Informed** Sensors referesh the temperature value
3. **Filtering**: Raw value is processed through MMA filter
4. **Threshold Check**: Filtered value is compared against last sent value ± threshold
5. **NBU Communication**: If threshold is exceeded:
    - XTAL32M calibration is performed (if LUT is available)
    - Temperature value is sent to NBU
    - Last sent value is updated

```
Temperature Request
        ↓
ADC Interrupt - Measurement is ready
        ↓
Raw Temperature Reading
        ↓
Sensors Module Informed - Temperature refresh
        ↓
MMA Filter Processing
        ↓
Threshold Check: |filtered - last_sent| > threshold?
    ↓                ↓
   YES               NO
    ↓
LUT Available?
  ↓      ↓
 YES     NO
```

(continues on next page)

(continued from previous page)

```
  ↓       ↓
XTAL32M     ↓
Calibration ↓
  ↓       ↓

    ↓
Send Temperature to NBU
    ↓
Update Last Value Sent to NBU
```

Platform Configuration Macros:

```
// Temperature filter size (number of samples for averaging)
#define PLATFORM_TEMPERATURE_FILTER_SIZE 4U

// Threshold for sending temperature to NBU (in tenths of degrees Celsius)
#define PLATFORM_TEMP_SENT_NBU_THRESHOLD 10  // 1°C
```

API Usage Examples

Manual Temperature Measurement

```
int32_t temperature1, temperature2;
SENSORS_TriggerTemperatureMeasurement();
...
temperature1 = (SENSORS_RefreshTemperatureValue())/10;
temperature2 = (SENSORS_GetTemperature())/10;
```

In this case temperature1 is equal to temperature2, both are in degree celsius.

Battery Level Measurement

```
uint8_t batteryLevel;
SENSORS_TriggerBatteryMeasurement();
...
batteryLevel = SENSORS_RefreshBatteryLevel();
// batteryLevel is now in percentage (0-100%)
```

Handling Concurrent Requests

```
// First request - will be accepted
SENSORS_TriggerTemperatureMeasurement();

// Second request while first is ongoing - will be dropped silently
SENSORS_TriggerBatteryMeasurement();  // This will be ignored

// Wait for first measurement to complete
int32_t temp = SENSORS_RefreshTemperatureValue();

// Now battery measurement can be triggered
SENSORS_TriggerBatteryMeasurement();  // This will be accepted
```

Low Power Optimization - Wake-up Temperature Measurement

```
// In low power exit callback (interrupts masked, scheduler disabled)
/* Trig temperature measurement on wake-up.
 * If a temperature change is detected,
 * the new value will be sent to the NBU for appropriate XTAL32M trimming.
 * During channel sounding measurements, this temperature is also used for RTT compensation.
 * Since this function runs with interrupts masked and the scheduler disabled,
 * the unsafe variant must be used to avoid mutex acquisition.
 */
SENSORS_TriggerTemperatureMeasurementUnsafe();
```

This approach optimizes power consumption and provides additional benefits:

- **XTAL32M Trimming**: Temperature changes are sent to NBU for crystal oscillator calibration only if they exceed the configured threshold after filtering
- **RTT Compensation**: This temperature data is used by the NBU for RTT compensation during channel sounding measurements
- **Safe Execution**: Uses the unsafe variant to avoid mutex acquisition in interrupt context with scheduler disabled In case of periodic measurement:
- **Power Optimization**: Triggers temperature measurements when the system is already awake, avoiding dedicated timer wake-ups
- **Timer Reset**: Resets the periodic measurement timer to prevent unnecessary wake-ups

  Note: This optimization is implemented by default in wireless platform examples when gAppUseSensors_d is enabled. The temperature measurement is automatically triggered in the low power exit callback (BOARD_ExitLowPowerCb()) in examples/_common/project_segments/wireless/wireless_mcu/board_lp.c.

Constant macro definitions

Name :

```
#define VALUE_NOT_AVAILABLE_8 0xFFu
#define VALUE_NOT_AVAILABLE_32 0xFFFFFFFFu
```

Description :

Defines the error value that can be compared to the value obtain on the ADC.

SFC : Smart Frequency Calibration Overview

The Smart Frequency Calibration module provides operations and calibration for the FRO32K source clock. This module is split between main core and Radio core:

- fwk_rf_sfc.[ch]: RF_SFC module on Radio core that provides Main FRO32K measurement/calibration and state machine in synchornization with Radio domain activities. See details below.
- fwk_sfc.h: SFC module on host core that provides type definition for usage with fwk_platform_ics.[ch] with PLATFORM_FwkSrvSetRfSfcConfig() API and fwk_platform_ble.c for received callback from the NBU core

Host SFC Module

Algorithm parametrization

This module provides ability to configure the RF_SFC module by sending message to Radio core through fwk_platform_ics.c PLATFORM_FwkSrvSetRfSfcConfig():

- Filter size
- Maximum ppm threshold
- Maximum calibration interval
- Number of sample in filter to swicth from convergence to monitor mode

Ppm target

The ppm target is the deviation from the target clock accepted by the algorithm. When the deviation is larger than the ppm target. The algorithm will update the trimming value and reset the filter. The ppm target cannot be more aggressive RF_SFC_MAXIMAL_PPM_TARGET in order to avoid having to update trimming value at each measurement.

Filter size

Filter size must be included between RF_SFC_MINIMAL_FILTER_SIZE and RF_SFC_MAXIMAL_FILTER_SIZE. See *Filtering and Frequency estimation* section for more details on the parameter.

Maximum calibration interval

In monitor mode, new measurement are triggered by lowpower entry/exit. If the NBU core has a lot of radio activity it could never enter lowpower. The maximum calibration interval is here to ensure a measurement is done regularly. When executing idle the SFC module checks when the last measurement has been done, if it has been too long, it reset the filter and forces a new measurement

Trig sample number

The trig sample number is the number of samples needed by the algorithm in its filter to switch from convergence to monitor mode. Having more than one sample in convergence mode allows to confirm the trimming value that we have set.

SFC debug information

On the other way, the RF_SFC from Radio core sends back notifications to SFC module on main core using RX callback PLATFORM_RegisterFroNotificationCallback() from fwk_platform_ics.h and such information:

- last measured frequency
- average ppm from 32768Khz frequency
- last ppm measured from 32768Khz frequency
- FRO trimming value

RF_SFC module

The RF_SFC module provides the functionality to calibrate the FRO32K source clock during Initialization and radio activity.

The RF_SFC is mostly used on XTAL32K less solution when no 32Khz crystal is soldered on the board. It allows to calibrate the FRO32K source clock to the desired frequency to keep Radio time base within the allowed tolerance given by the connectivity standards. However, even on a XTAL32K solution, the RF_SFC is also used during Initialization until the XTAL32K is up and running in the system. The system firstly runs on the FRO32K clock source then switch to the XTAL32K clock source when it is ready with enough accuracy. This allows to save significant boot time as the FRO32K start up (including calibration) is much faster compared to XTAL32K .

This module will handle:

- FRO32K clock frequency measurement against 32Mhz crystal. It schedules appropriately the start of the measurement and gets the result when completed,
- Filter and estimate the 32Khz frequency value and error by averaging from the last measurements,
- FRO32K calibration in order to update the trimming value to reduce the frequency error on the clock.

The targeted frequency offset shall be within 200ppm. The RF_SFC will handle two modes of operation:

- Convergence mode: when frequency estimation is above 200pm,
- Monitor mode: when frequency estimation is below 200pm.

The RF_SFC module works in active and all low power modes on NBU domain, or on host application domain except power down mode. Power down mode on host application domain is not supported with the FRO32K configuration as clock source.

Feature enablement

Enabling the FRO32K is done by calling the PLATFORM_InitFro32K() function during application initialization in hardware_init.c file, in BOARD_InitHardware() function. If FRO32K is not enabled, Oscillator XTAL32K shall be called instead by calling PLATFORM_InitOsc32K() function. The call to PLATFORM_InitFro32K() from BOARD_InitHardware() can be done by setting the Compilation flag gBoardUseFro32k_d to 1 in hardware_init.c or any header files included from this file.

```
#define gBoardUseFro32k_d       1
```

Detailed description

Frequency measurements

When NBU low power is enabled, the frequency measurements are triggered on Low power wake-up by HW signal. The SFC process called from Idle task will check regularly the completion of the frequency measurement. When the measurement is done, it goes to filtering and frequency estimation process. The frequency measurement duration depends on monitor mode or convergence mode: In convergence mode, the frequency measurement duration is 0.5ms while it is 2ms in monitor mode. In monitor mode, the duration value remains less than the minimal radio activity duration so it does not impact the low power consumption in monitoring mode.

Filtering and Frequency estimation

The FRO32KHz frequency measurement values are noisy because of thermal noise on the FRO32K itself. Also, the frequency measurement can introduce some error. In monitoring mode, it is required to filter the measurements by applying an exponential filter. new_estimation = (new_measurement + ((1 « n) -1) * last_estimation) » n

Default value for n is 7 (meaning 128 samples in the averaging window).

Frequency calibration

When the frequency estimation gets higher than the targeted 200ppm target, the RF_SFC updates the trimming value for one positive or negative increment. For this purpose, it requires to:

- wake up the host application domain and keep the domain active,
- update the trim register of the FRO32K , this register is used to trim the capacitance value of the FRO32K,
- re-allow the host application domain to enter low power.

A slight power impact is expected during a calibration update due to host domain wake-up.

Operational modes

When the low power mode is enabled on NBU power domain, RF SFC handles two modes of operation: convergence and monitor modes. However, when low power is disabled on NBU power domain, only convergence mode is supported.

Convergence mode

Convergence mode is used when the estimated FRO32K frequency is above 200ppm or when the filter has been reset. Typically this occurs :

- During Power ON reset or other reset when NBU is switched OFF
- When temperature varies and FRO32K frequency deviates outside 200ppm threshold target
- When no calibration has been done during some time as we discard old values that could influence the algorithm

The convergence mode process typically starts with a FRO32K trim register update, performs a frequency measurement and the FRO32K trim register is updated until the measured frequency gets below 200ppm. These operations are repeated in a loop until the estimated frequency value gets below 200ppm. When below 200ppm during multiple measurements, the RC SFC switches to Monitoring mode. The convergence mode is only a transition mode to monitoring mode. In convergence mode, the NBU power domain does not go to low power. The convergence mode time duration depends on the initial frequency error of the FR032K. Default frequency measurement duration is 0.5ms so 20 measurements (given as example only) will require less than 10 ms to converge.

Monitoring mode

Monitoring mode is used when the estimated FRO32K frequency is below 200ppm. In this mode, the measurement is triggered on NBU domain wake up from low power mode using an internal hardware signal. The exponential filter is applied to compute the frequency estimation. If the frequency estimation value is still within 200ppm, the NBU power domain is allowed to go to low power. If the estimated value gets above the 200ppm threshold, the RF SFC switch back to convergence mode. The trim register is updated by one increment (positive or negative) and because the frequency has been adjusted and changed, the estimated filtered frequency is reset to discard all previous measurements. Going back to convergence mode typically happens during a temperature gradient. If the temperature is constant, it is not expected to have the estimated value to go beyond 200ppm so no calibration should be required.

Initialization and configuration

During initialization, the RF SFC module will block the Radio Software until monitoring mode is reached. This is to prevent the radio from running with an inaccurate time base due to an important 32k clock frequency error.

Initialization and configuration is done by the NBU core. The configuration parameters can set up:

- The 200ppm target threshold. This value shall be 200ppm or higher.
- The filtering number n (see section above), It shall be between 0 and 8. Default is 7 which is similar to an averaging filter of 128 samples. A higher value will be more robust against noise. A lower value will track temperature variation more faster.

In order to prevent the host application domain from going into power down mode (power down mode not supported with FRO32K as clock source), the fwkSrvLowPowerConstraintCallbacks functions structure is registered to the Framework service on host application core from fwk_platform_lowpower.c file, PLATFORM_LowPowerInit() function. The NBU code applies a

low power Deep Sleep constraint to the application core. This constraint is released when the NBU firmware has no activity to do and re-applied when a new activity starts.

Lowpower impact

Power impact during active mode:

In monitoring mode (this should be 99.9% of the time if temperature does not vary), the FRO32KHz frequency measurements are performed during a Radio activity so it does not increase the active current as the sources clocks are already active. Also, it does not increase the active time as the measurement takes less time than an advertising event or connection event so no impact on power consumption.

The main power impact will be in convergence mode. In this case, measurements/calibrations are done in loop until the monitoring mode is reached (frequency error less than 200ppm). This could happen:

- During power ON reset,
- When temperature varies: The frequency will deviate from 32768Hz and FRO32K trimming register correction will need to be updated for that,
- When no measurement has been done during some time as we cannot predict if the FRO has drifted, so we discard older values and start convergence mode.

When FRO32K frequency needs to be adjusted, the NBU core will wake-up the main power domain and will update the FRO32K trimming register.

Power impact during low power mode:

The power consumption in low power mode will increase slightly due to running FRO32K compared to XTAL32K. The power consumption of FRO32K typically consumes 350nA while it is only 100nA with XTAL32K. Refer to the product datasheet for the exact numbers.

Chapter 4

RTOS

4.1 FreeRTOS

4.1.1 FreeRTOS kernel

Open source RTOS kernel for small devices.

FreeRTOS kernel for MCUXpresso SDK Readme

MCUXpresso SDK: FreeRTOS Kernel NXP Integration This repository is the NXP integration layer for the FreeRTOS kernel (https://github.com/FreeRTOS/FreeRTOS-Kernel). It allows original FreeRTOS kernel upstream sources build in MCUXpresso SDK. It is part of the MCUXpresso SDK overall delivery which is composed of several sub-repositories/projects. Navigate to the top/parent repository mcuxsdk-manifests(https://github.com/nxp-mcuxpresso/mcuxsdk-manifests) for the complete delivery of MCUXpresso SDK.

For more information about the FreeRTOS kernel repo adoption see README_mcuxsdk.md: FreeRTOS kernel for MCUXpresso SDK Readme document.

FreeRTOS kernel for MCUXpresso SDK Overview

The purpose of this document is to describes the FreeRTOS kernel repo integration into the NXP MCUXpresso Software Development Kit: mcuxsdk. MCUXpresso SDK provides a comprehensive development solutions designed to optimize, ease, and help accelerate embedded system development of applications based on MCUs from NXP. This project involves the FreeRTOS kernel repo fork with:

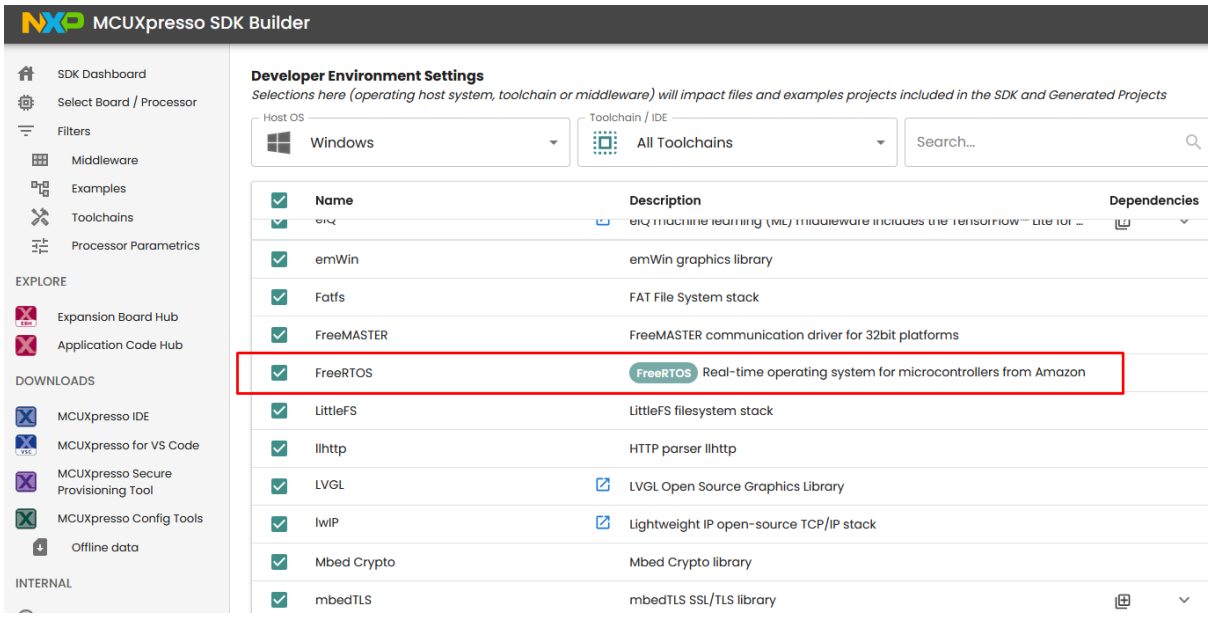
- cmake and Kconfig support to allow the configuration and build in MCUXpresso SDK ecosystem
- FreeRTOS OS additions, such as FreeRTOS driver wrappers, RTOS ready FatFs file system, and the implementation of FreeRTOS tickless mode

The history of changes in FreeRTOS kernel repo for MCUXpresso SDK are summarized in *CHANGELOG.md* file.

The MCUXpresso SDK framework also contains a set of FreeRTOS examples which show basic FreeRTOS OS features. This makes it easy to start a new FreeRTOS project or begin experimenting with FreeRTOS OS. Selected drivers and middleware are RTOS ready with related FreeRTOS adaptation layer.

FreeRTOS example applications

The FreeRTOS examples are written to demonstrate basic FreeRTOS features and the interaction between peripheral drivers and the RTOS.



List of examples

The list of freertos_examples, their description and availability for individual supported MCUXpresso SDK development boards can be obtained here: https://mcuxpresso.nxp.com/mcuxsdk/latest/html/examples/freertos_examples/index.html

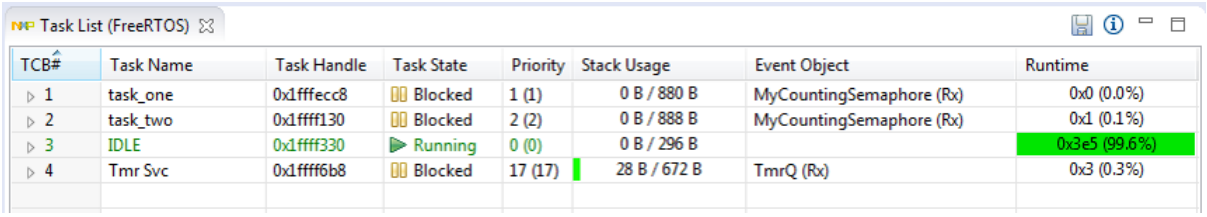
Location of examples

The FreeRTOS examples are located in mcuxsdk-examples repository, see the freertos_examples folder.

Once using MCUXpresso SDK zip packages created via the MCUXpresso SDK Builder the FreeRTOS kernel library and associated freertos_examples are added into final zip package once FreeRTOS components is selected on the Developer Environment Settings page:

The FreeRTOS examples in MCUXpresso SDK zip packages are located in <MCUXpressoSDK_install_dir>/boards/<board_name>/freertos_examples/ subfolders.

Building a FreeRTOS example application



For information how to use the cmake and Kconfig based build and configuration system and how to build freertos_examples visit: MCUXpresso SDK documentation for Build And Configuration MCUXpresso SDK Getting Start Guide

Tip: To list all FreeRTOS example projects and targets that can be built via the west build command, use this west list_project command in mcuxsdk workspace:

```
west list_project -p examples/freertos_examples
```

FreeRTOS aware debugger plugin

NXP provides FreeRTOS task aware debugger for GDB. The plugin is compatible with Eclipse-based (MCUXpressoIDE) and is available after the installation.

TCB#	Task Name	Task Handle	Task State	Priority	Stack Usage	Event Object	Runtime
1	task_one	0x1fffecc8	Blocked	1 (1)	0 B / 880 B	MyCountingSemaphore (Rx)	0x0 (0.0%)
2	task_two	0x1ffff130	Blocked	2 (2)	0 B / 888 B	MyCountingSemaphore (Rx)	0x1 (0.1%)

4	Tmr Svc	0x1ffff6b8	Blocked	17 (17)	28 B / 672 B	TmrQ (Rx)	0x3 (0.3%)

FreeRTOS kernel for MCUXpresso SDK ChangeLog

Changelog FreeRTOS kernel for MCUXpresso SDK All notable changes to this project will be documented in this file.

The format is based on Keep a Changelog, and this project adheres to Semantic Versioning.

[Unreleased]

Fixed

- Temporary workaround for FreeRTOS-Kernel upstream bug #1480: stray URL (http://files.iar.com/ftp/pub/box/bxarm-9.60.3.deb) accidentally placed outside /* */ comment delimiters on line 466 of the IAR CM33/CM55/CM85 TrustZone non-secure portasm.s files (introduced in upstream commit 78e0cc778a, PR #1195). Fixed copies are placed under portable/IAR/ARM_CM{33,55,85}/non_secure/portasm.s and the CMakeLists.txt SOURCES entries for the cm33/cm55/cm85_trustzone.non_secure IAR toolchain blocks are redirected to those copies. Revert the three CMakeLists.txt lines once the upstream fix is merged and the freertos-kernel-upstream revision is bumped past it, then delete portable/IAR/ARM_CM{33,55,85}/ from this repo.

Added

[11.2.0_rev0]

- update amazon freertos version

[11.1.0_rev0]

- update amazon freertos version

[11.0.1_rev0]

- update amazon freertos version

[10.5.1_rev0]

- update amazon freertos version

[10.4.3_rev1]

- Apply CM33 security fix from 10.4.3-LTS-Patch-2. See rtos\freertos\freertos_kernel\History.txt
- Apply CM33 security fix from 10.4.3-LTS-Patch-1. See rtos\freertos\freertos_kernel\History.txt

[10.4.3_rev0]

- update amazon freertos version.

[10.4.3_rev0]

- update amazon freertos version.

[9.0.0_rev3]

- New features:
  - Tickless idle mode support for Cortex-A7. Add fsl_tickless_epit.c and fsl_tickless_generic.h in portable/IAR/ARM_CA9 folder.
  - Enabled float context saving in IAR for Cortex-A7. Added configUSE_TASK_FPU_SUPPORT macros. Modified port.c and portmacro.h in portable/IAR/ARM_CA9 folder.
- Other changes:
  - Transformed ARM_CM core specific tickless low power support into generic form under freertos/Source/portable/low_power_tickless/.

[9.0.0_rev2]

- New features:
  - Enabled MCUXpresso thread aware debugging. Add freertos_tasks_c_additions.h and configINCLUDE_FREERTOS_TASK_C_ADDITIONS_H and configFREERTOS_MEMORY_SCHEME macros.

[9.0.0_rev1]

- New features:
  - Enabled -flto optimization in GCC by adding **attribute**((used)) for vTaskSwitchContext.
  - Enabled KDS Task Aware Debugger. Apply FreeRTOS patch to enable configRECORD_STACK_HIGH_ADDRESS macro. Modified files are task.c and FreeRTOS.h.

[9.0.0_rev0]

- New features:
  - Example freertos_sem_static.
  - Static allocation support RTOS driver wrappers.
- Other changes:
  - Tickless idle rework. Support for different timers is in separated files (fsl_tickless_systick.c, fsl_tickless_lptmr.c).
  - Removed configuration option configSYSTICK_USE_LOW_POWER_TIMER. Low power timer is now selected by linking of apropriate file fsl_tickless_lptmr.c.
  - Removed configOVERRIDE_DEFAULT_TICK_CONFIGURATION in RVDS port. Use of **attribute**((weak)) is the preferred solution. Not same as _weak!

[8.2.3]

- New features:
  - Tickless idle mode support.
  - Added template application for Kinetis Expert (KEx) tool (template_application).
- Other changes:
  - Folder structure reduction. Keep only Kinetis related parts.

FreeRTOS kernel Readme

4.1.2 FreeRTOS drivers

This is set of NXP provided FreeRTOS reentrant bus drivers.

4.1.3 backoffalgorithm

Algorithm for calculating exponential backoff with jitter for network retry attempts.

Readme

MCUXpresso SDK: backoffAlgorithm Library NXP Integration This repository is the NXP integration layer for the backoffAlgorithm library (https://github.com/FreeRTOS/backoffalgorithm). It allows original backoffAlgorithm upstream sources build in MCUXpresso SDK. It is part of the MCUXpresso SDK overall delivery which is composed of several sub-repositories/projects. JSON parser.

Readme

MCUXpresso SDK: coreJSON Library NXP Integration This repository is the NXP integration layer for the coreJSON library (https://github.com/FreeRTOS/corejson). It allows original coreJSON upstream sources build in MCUXpresso SDK. It is part of the MCUXpresso SDK overall delivery which is composed of several sub-repositories/projects. Navigate to the top/parent repository mcuxsdk-manifests(https://github.com/nxp-mcuxpresso/mcuxsdk-manifests) for the complete delivery of MCUXpresso SDK.

4.1.6 coremqtt

MQTT publish/subscribe messaging library.

MCUXpresso SDK: coreMQTT Library NXP Integration

This repository is the NXP integration layer for the coreMQTT library (https://github.com/FreeRTOS/coremqtt). It allows original coreMQTT upstream sources build in MCUXpresso SDK. It is part of the MCUXpresso SDK overall delivery which is composed of several sub-repositories/projects. Navigate to the top/parent repository mcuxsdk-manifests(https://github.com/nxp-mcuxpresso/mcuxsdk-manifests) for the complete delivery of MCUXpresso SDK.

4.1.7 corepkcs11

PKCS #11 key management library.

Readme

MCUXpresso SDK: corePKCS11 Library NXP Integration This repository is the NXP integration layer for the PKCS #11 key management library (https://github.com/FreeRTOS/corePKCS11). It allows original PKCS #11 key management upstream sources build in MCUXpresso SDK. It is part of the MCUXpresso SDK overall delivery which is composed of several sub-repositories/projects. Navigate to the top/parent repository mcuxsdk-manifests(https://github.com/nxp-mcuxpresso/mcuxsdk-manifests) for the complete delivery of MCUXpresso SDK.

4.1.8 freertos-plus-tcp

Open source RTOS FreeRTOS Plus TCP.

Readme

MCUXpresso SDK: FreeRTOS-Plus-TCP Library NXP Integration This repository is the NXP integration layer for the FreeRTOS-Plus-TCP library (https://github.com/FreeRTOS/freertos-plus-tcp). It allows original FreeRTOS-Plus-TCP upstream sources build in MCUXpresso SDK. It is part of the MCUXpresso SDK overall delivery which is composed of several sub-repositories/projects. Navigate to the top/parent repository mcuxsdk-manifests(https://github.com/nxp-mcuxpresso/mcuxsdk-manifests) for the complete delivery of MCUXpresso SDK.
